VOL. VI, No. 1

JULY 7, 1900

\$3.00 PER ANNUM

Dishonoring Military Medical Officers Dishonors the Nation.—Mr. Burdett-Coutts has been showing in Parliament the natural results of the contemptible contempt of army medical men. The English army officer and the War Office have habitually neglected the Army Medical Department. It has always been seriously undermanned, its members scarcely recognized as officers, usually excluded from mention in dispatches or public votes of thanks, with little facility for study, or leave for private research. As a consequence, there has been deplorable suffering of the sick and wounded in South Africa, and the people have another reason for indignation at the War Office. It is hard for men whose business is killing to have much respect for men whose business is only the little matter of saving life. This sin of our own services in the United States has not been so heinous as that of the Britisher, but it has been bad enough, especially in the Navy. If we had a united profession and a corporate voice, influence could soon remedy many abuses that now disgrace us. The encouragement of original research, the gathering and publication of medical experience, opportunities for postgraduate study, the supplying of the best medical journals and books to members of the corps—these and many such things are sadly needed.

The annual spring crop of honorary degrees gives some evidences that the best of our colleges and universities are awarding their honors in such a way as to make them worth having. We are glad to notice the names of two eminent medical men among others who have been honored: Professor William H. Welch, of Johns Hopkins University, received the honorary degree of Doctor of Law from Harvard, and the eminent surgeon Louis A. Stimson received the same honor from his alma mater, Yale. Among the smaller colleges the awards are much less discriminating, and hence honorary degrees have become so cheap as to be almost a disgrace in certain cases. Even among our better colleges and universities the proportion of politicians favored is strikingly large and the recipients of the honors are often of questionable character. Out of 17 honorary degrees by three of our leading universities four were awarded to politicians, four to college presidents, two each to ministers of the gospel, doctors, and eminent educators, and one to an eminent professor, one to a foreign ambassador, one to a well-

known writer. In the past the proportion of such awards to eminent medical men has been strikingly small, and makes it very evident that the medical profession is not the one to choose if we are seeking a prominent position in the eyes of the public. If awarded with proper care and discrimination the honorary degree takes the place, to some extent, of the honors which are conferred in foreign countries by the knighthood, etc., and they are not without some worth. The conferring of degrees on eminent scholars, other than their own alumni, by prominent institutions is an evidence of growing breadth and toleration; it tends to promote a friendly spirit between rival institutions and should become more general.

Anniversary and Memorial Publications in the United States.—Those to whom the method of honoring the life or the memory of a distinguished and beloved teacher, as illustrated in the *Festschrift*, prepared in honor of Drs. Jacobi and Welch, seems wholly new in this country, appear to be unaware of the fact that not less than seven years ago the "Wilder Quarter-Century Book," an octavo volume of 500 pages, containing a collection of original papers on physiologic subjects, was published by a number of former pupils of the distinguished professor of physiology, comparative anatomy, and zoology, in Cornell University, on the occasion of the quarter-centennial celebration of the opening of that university.

"Patent Medicine Profits."—Some illuminating facts are given publication in the prospectus of a new pharmaceutical company in which medical men are invited to become stockholders. The company has been organized for the purpose of manufacturing and selling a new anesthetic and other proprietary medicines. It is incorporated with a capital stock of 0, so many million dollars! "The operations of the company have been inaugurated on quite an extensive scale and the product is now being manufactured and has been placed on sale . . . and has been extensively advertised." "A large number of physicians, dentists, and professional nurses . . . as well as many prominent citizens" are said to be stockholders and to be prescribing and recommending this new remedy, which is recommended for the relief of some 30 painful conditions. One million dollars of preferred

stock is to be sold, and the proceeds are to be used to advertise the product and bring it extensively upon the market. Nowhere, however, is even the slightest hint given as to the nature or composition of this highly lauded product from whose sale, "if properly pushed," hope of "a princely fortune" is held out. The president of the company and the discoverer of the new remedy is said to be a professional man, and one of the directors attaches M.D. to his name. Testimonials as to the efficacy of the remedy are signed by lawyers, housewives, doctors, merchants, policemen, churchmen, manufacturers, reporters, dentists, and others. The following inducements are offered for engaging in the enterprise and are reproduced from the original, with the omission of names:

"Profits on proprietary medical preparations are larger than those in any other line of manufacture.

"The fortunes built up by successful patent medicine concerns are something enormous and in no other way can so much money be made so quickly and so easily.

"The annual profits of the M— remedies, for instance, are something enormous.

"Although Professor M— commenced their manufacture only a few years ago, he is known to have invested out of one year's profits alone nearly a quarter of a million dollars in Philadelphia real estate.

"On January 1, 1900, he gave away \$2,000,000 to the city of Philadelphia for an orphanage institution.

"Dr. R. V. P— has spread his remedies all over the world and is believed to have made over \$10,000,000.

"The manufacturers of a certain emulsion have made an immense fortune, notwithstanding the fact that their emulsion is a simple one, well known to physicians long before they commenced preparing it.

"It is stated on reliable authority that the two sons of Mrs. A— have an income of \$900,000 a year each from their share in the profits of a sarsaparilla.

"One of the principal owners of a laxative syrup started out with nothing at all and within 10 years became a millionaire."

The Etiology of the Infectious Diseases.—One of the most interesting papers read before the Section on Practice of Medicine at the Atlantic City meeting of the American Medical Association was that by Dr. Eugene Wasdin, of the United States Marine-Hospital Service, on Yellow Fever: Its Nature and Causes. The commission appointed by the Surgeon-General of the Marine-Hospital Service, of which Dr. Wasdin was the senior member, seems to have established the etiologic significance of the *Bacillus icteroides* for yellow fever; but more important than this, if possible, is the determination of the portal of entry of the microorganism into the system. By blowing lycopodium powder containing dried cultures of the *Bacillus icteroides* into the respiratory tracts of dogs, the author succeeded in producing typical yellow fever in the animals. The localization of the microorganism in the respiratory tract as its first nidus of development would explain the sterility of the bodies of patients that have died, early in the disease, of a toxemia, before the bacillus had an opportunity of entering the circulation. In the laboratory used by the commission the disease seems to have extended from the dogs infected in one room

through an open door, to healthy animals in an adjoining room, in which no insufflation experiments had been made. Dr. Wasdin made the statement at a later session of the section, while discussing a paper on typhoid fever, that, in his opinion, in the majority of cases the portal of entry for the bacillus of Eberth was through the respiratory tract. When asked by one of the members of the section how he accounted for the Plymouth, Pa., epidemic, Dr. Wasdin replied that when people drank water they also washed with water, and the microorganisms left after the water had dried were the infecting organisms. Dr. Wasdin admitted that infection through the intestinal tract was possible. In favor of the respiratory tract as the portal of entry we may call attention to the earliest symptoms—pharyngitis and slight bronchial irritation, with, sometimes, a severe bronchitis, or even pneumonia. The epidemics that have been traced to contaminated milk as the cause and those due to the eating of raw oysters, however, point decidedly to infection through the alimentary tract. Again, the experiments of Paul Remlinger (*Ann. de l'Inst. Pasteur*, November, 1897), by which rats and rabbits fed on vegetables that had been artificially contaminated with Eberth's bacillus acquired an affection that presented the most marked analogies to human typhoid fever, both bacteriologically and anatomically, point also to the alimentary tract as the first area of infection in this disease. The entire subject, which has been considered definitely settled, thus seems to be opened again, and it is not unreasonable to suppose that further experiment will show that typhoid fever may begin as a respiratory-tract infection as well as an alimentary-tract infection.

Homeopathic Dogma and Practice.—In the city of Washington on June 21 the American Institute of Homeopathy unveiled with fitting ceremonies a monument of Samuel Hahnemann. President McKinley occupied the most prominent seat upon the platform, where sat also H. B. F. McFarland, Commissioner of the District, General John M. Wilson, and Mr. Cortel-you, Secretary to the President. Attorney-General Griggs delivered a short and spirited oration. The monument, very beautiful from an artistic standpoint, occupies one of the choicest positions in the city, facing the statues of General Winfield Scott and Daniel Webster.

Specialism, into which field the homeopaths have freely entered, occupied the greater part of the purely medical side of the week's transactions. The papers read did not differ materially in their points of view from papers upon similar subjects read before other medical bodies. It was at the meeting of the section on *Materia Medica*, "the backbone of homeopathy," as Dr. Charles Mohr of Philadelphia characterized this branch of medical science, that an idea of the present status of homeopathy could be formed. The four hours

to be devoted to *Materia Medica* were assigned to the last two days of the program. Owing to the time occupied in thanking the Monument Committee and the President of the United States, and to the intention of many members to leave before the scheduled time, exactly two hours were spent in reading and discussing papers. But four of the five papers upon heart-poisons were read. The first on the "Proving of *Crataegus Oxy*" was pronounced by a member, in the discussion which followed, to be "perfect nonsense." Dr. W. A. Dewey, of Ann Arbor, prefaced his short paper upon *Adonis vernalis* with the remark that he knew nothing of the drug, had never used it, and wrote only at the request of the chairman of the section.

In the discussion that followed two excellent papers upon the actions of *strophanthus* and *digitalis*, drugs not yet proved by the methods of Hahnemann, cases were reported successfully treated, the dose employed being the "orthodox" dose of the U. S. Pharmacopeia. The discussions were characterized throughout by the mutual misunderstanding of terms, by objections to the use of certain terms, *e. g.*, physiologic instead of pathogenetic action of drugs, and twice members were accused of treating patients "allopathically." The truth of these accusations was not denied.

The treatment of disease antipathically, in other words, "allopathically," was stated by Dr. E. C. Price, of Baltimore, to be right and proper under certain circumstances, *i. e.*, upon the failure of homeopathic remedies, "for Hahnemann says the first duty of a physician is to relieve the sick." Antipathic treatment, he also stated, was indicated in "emergency cases," and he advised the giving of stimulants, not depressants, to those suffering from nervous shock. Even Dr. Mohr, a homeopathist of the old school, while not admitting their "curative" power, makes use of the "palliative" properties of the orthodox doses of the "allopath."

Such doubts and disagreements with the principles of Hahnemann are, to use the words of a disciple present, "creeping into the journals, hospitals and colleges" of the homeopaths. Indeed the tendency of the whole meeting went to show that the term "homeopath" is but a trade designation and does not include adherence to the principle implied. And yet the "homeopaths" have raised in the capital of the United States a monument resembling an altar, upon the base of which are inscribed the words, "*Similia Similibus Curantur*."

All this in spite of the modified definition of the term "homeopathic physician," offered by Dr. T. Y. Kinne, and adopted after a debate of considerable length: "A homeopathic physician is one who adds to his general knowledge of medicine a special knowledge of homeopathic therapeutics and observes the law of *similia*."

The erection of the monument to Hahnemann is not

fully appreciated by the profession of the United States. Nothing could give homeopathy more dignity and importance than this. Except for the statue of Gross there is nothing in art in Washington that bears any relation to medical science. But now the founder of homeopathy will always be shown in eternal bronze to the visiting thousands.

It is highly regrettable that funds cannot be raised to pay for the Rush monument.

Medical Sermonets, No. 19. The Physician's Vacation.—With the coming of the vacation season every wise physician will seriously consider the duty of securing a period of rest and change. For him it is indeed a duty, because, of all members of the community, his usual work is most ceaseless. He alone of all may not have even the commanded one day in seven—for the most literal of theologians would not require that the sick should be neglected on Sunday. Hence, at least his Sundays may, as it were, be stored up for the greater part of the year and gathered and utilized in the lump when he can best secure the occasion for a holiday. It is perhaps true that, owing to the peculiarity of his work the longer vacation of weeks may be more easily taken than the short one of days. Among the minor advantages is possibly the better understanding and good feeling that follows the mutual care of another's practice by the colleague, and the return favor when his time of rest shall come.

But beyond all such minor reasons remains the fact that the physician's duty of holiday-taking is trebly advisable. He owes it first to his patients, because the strenuousness of his life is so great that without the occasional easing-up of the strain the best and most effective therapeutics and medical service is impossible. The problems we have to solve, the tension at which the intellect has to be kept, the endlessly repetitive drains upon the emotional and sympathetic nature that must be endured, will, without rest, reduce the keenness of mind and the special ability to a dulness and routine that is harmful to medical art. It is, therefore, for the patient's good that his doctor should go holidaying.

In the second place it is due his family, and in the equally important third place it is due himself. There is another nature besides human nature, and to know this is imperative upon one having so little time for that as the medical man. The charm of nature-love is inexhaustible, and its instruction many-sided. If solitude is well for others, it is peculiarly so for one whose daily life is always in close association with many persons and when suffering and trial are inevitable concomitants. To escape from it all and witness the play of manifold life hardly touched by disease is not less than a duty and a necessity. The distinctive blessedness of such solitude is that it teaches one to become better acquainted not only with wife and children, but with oneself. In the unremitting call for outgoing and help one is likely to leave himself and the friendship with that self too far out of mind. The *persona* (or mask) leaves the personality out of sight and out of mind. In the social engine we may become only cogs in the great wheel of the objective, a bit of the mechanism grinding out the community's grist according to the demands of circumstance or fate. In the silences of the hills and the woods and the seashore we can leave all that, and rediscovering ourselves regain some of the freedom we should never forfeit and never be wholly without. Many, perhaps the vast majority, judging from the pitiable fashion of crowd seeking and crowd-loving, cannot endure the burden of themselves, but surely physicians are not of these, and they will therefore avoid noise and numbers and seek the healing of the woods and mountains.

Correspondence.

SIMULTANEOUS DISLOCATION OF BOTH SHOULDERS.

By S. VIRGIL MERRITT, M.D.,
of Fall River, N. Y.*To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—*

A FEW days ago I saw with Dr. D. E. Cone a rather unusual case, which I think deserves mention. A woman of 60, who weighed about 160 pounds, and had no history of previous injury, fell 3½ feet from a stepladder with both arms extended over her head. The resulting injury was a simultaneous dislocation of both shoulder-joints (subglenoid in each). The luxations were easily reduced under ether anesthesia. There was no other injury beyond a few bruises.

CONTAGION AND INFECTION.

By JOHN N. BELL, M.D.,
of Detroit.*To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—*

IN the JOURNAL of June 2, Dr. L. F. Flick, in his excellent paper on "The Registration of Tuberculosis" speaks of the loose manner in which the words contagious and infectious are used in medical literature, and, as an exemplification of the difference between a contagious and an infectious disease cites smallpox and malaria. A little farther on in the same paper he says "malaria is purely contagious." It would appear from this that Dr. Flick is himself guilty of a little laxity in construction.

MENSTRUATION SOON AFTER BIRTH.

By ALBERT H. WALES, M.D.,
of Chicago.*To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—*

I HAD scarcely finished reading the communication of Dr. H. McVicker Smith in a recent number of your valuable journal, relative to his case of precocious menstruation, when it was my fortune to meet with a similar experience. The labor was perfectly physiologic and of short duration; 4 days later I was notified by the nurse that she had discovered a discharge of blood on the napkin. The flow gradually increased until it assumed the dignity of a free menstrual discharge; it slowly diminished and disappeared on the ninth day after birth.

PAN-AMERICAN MEDICAL CONGRESS.

By HENRY B. YOUNG, M.D.,
of Burlington, Iowa.*To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—*

APPROX of the Pan-American Medical Congress which is scheduled to convene in Havana, Cuba, on December 26, 1900, I inquire if it is not possible to amend the schedule so that it will name a later date for the meeting? I do not know positively how it may be with others, but think many would like to attend, *provided* they could do so and not miss their Christmas at home. Then again, January 1, usually is settling day, the day when we have to pay our debts and expect others to pay us. To be absent from home at such a time creates a bad impression upon our creditors, and gives our debtors an excuse for delay. By all means let us have the date January 26, 1901 (or thereabouts), if possible. At that date those of us who live in the north will have an

extra inducement to go—and miss the disagreeable February weather.

COAL IN THE APPENDIX.

By WALTER LATHROP, M.D.,
of Hazleton, Pa.*To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—*

WE have heard at various times of foreign bodies in the appendix, but, aside from enteroliths, they are not common.

June 19 I operated on a young man who had a severe attack of appendicitis. I found dense adhesions from previous attacks, and after a considerable time succeeded in separating the adhesions, and removed the appendix, which was very large, but quite short, resembling a medium-sized date; upon inserting a probe I felt some hard substance, and after removing it, I found a piece of pure *anthracite coal*. How this got in the appendix is a mystery, but my assistant made the plausible suggestion, that this piece was an agglutination of coal dust, the man being a miner for a number of years. The specimen is flat, and about ½ inch long, ⅛ inch thick.

The appendix was perforated at its cecal attachment, the coal lying just above the opening. The genuineness of this specimen was vouched for by seven physicians who were present at the operation, so that I think the case can stand as unique in the annals of foreign bodies in the appendix.

UNSCIENTIFIC ARGUMENTS.

By G. BETTON MASSEY, M.D.,
of Philadelphia.*To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—*

IN the report of a meeting of the Pittsburg Academy of Medicine in the JOURNAL of June 16, page 1342, Dr. D. D. Simpson, if correctly reported, employed an ignoble weapon against the cataphoric treatment of malignant disease by remarking that "Massey had written much concerning electrical treatment in gynecologic cases, and claims remarkable results, but other men fail to get such results for some reason." This statement was unworthy of a place in scientific argument, for two reasons, one that it contained an insinuation against my honesty, for in no other light could his opinion of my work in gynecology bear upon the subject then under discussion, which was malignant disease. I care nothing for the gentleman's private opinion of my veracity, under the circumstances, but decidedly object to its public presentation. The other reason why such reckless statements should secure an equally public denial is the incorrectness of this opinion as to the value of electricity in gynecology in other hands than mine. Surely anyone who heard the eloquent advocacy of electricity in gynecology by so able a surgeon as Thaddeus A. Reamy, of Cincinnati, in the gynecological section at the Columbus meeting last year, would be differently impressed. I am in a position to prove by my correspondence and otherwise, that there is an increasing number of general practitioners using electricity in gynecologic practice, and that by this means they succeed in averting a large number of operations of the nature that Dr. Simpson was illustrating by a specimen that evening. This discussion at the Pittsburg Academy referred to the possible value of the cataphoric method in destroying malignant growths of the conjunctiva, and as this method can be most beautifully employed in small growths in that region, being bloodless and absolutely controllable, it is hoped that these extraneous matters will not be permitted to interfere with its usefulness.

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Airings for Children.—The charitable societies are trying to raise money to provide outings for the children of poor families. Enough applicants have been received by the Country Week Association to fill the country boarding-houses within a radius of 50 miles.

Headache Pills Cause Death.—On June 27 the dead body of an unknown man was found in a barn near Blue Ball, Lancaster County. A vial of "headache pills" found by his side caused the coroner's jury to pronounce death due to neuralgia of the heart caused by taking too many of the pills.

Pennsylvania College of Dental Surgery.—The chair of chemistry in the faculty of Pennsylvania College of Dental Surgery is vacant, owing to the retirement of Prof. Henry Leffmann. The Board of Corporators will meet July 16, and the matter of electing a professor will then be acted upon. Application should be made to Joseph Pettit, M.D., 1010 Land Title Building, Philadelphia.

The State Board of Medical Examiners held an examination in Industrial Hall, Philadelphia, June 26-29. It was conducted by Drs. Beates, McCormick, Hamaker, Ramsey and Hulshizer. At the same time an examination was conducted in Pittsburg by Drs. Foster and McConnell. The Philadelphia class numbered 210, of which 15 were women. The class at Pittsburg numbered 110, making a total of 320 applicants; of these 20 were reexamined.

Vital Statistics of Philadelphia for the week ended June 30, 1900:

Total mortality	Cases.	497 Deaths.
Disease.		
Inflammation of appendix 1, colon 1, brain 13, bronchi 6, kidneys 14, heart 2, liver 1, lungs 18, pericardium 1, peritoneum 10, pleura 1, stomach and bowels 21, uterus 1, pharynx 1, tonsils 1		93
Cholera infantum 55, cholera morbus 1		56
Pulmonary tuberculosis		51
Marasmus 18, inanition 16, debility 5		39
Apoplexy 22, paralysis 7, softening of brain 5		34
Heart—disease of 29, fatty degeneration of 1, enlargement of 1		31
Casualties		20
Carcinoma of—breast 5, liver 4, neck 1, stomach 5, thigh 1, uterus 5		20
Convulsions 16, puerperal convulsions 2		18
Diphtheria	76	15
Bright's disease		12
Old age		10
Uremia		8
Typhoid fever	13	7
Brain—congestion of 4, hemorrhage of 1, dropsy of 2		7
Liver—cirrhosis of 4, disease of 1, abscess of 2		7
Teething		6
Lungs—abscess of 1, edema of 3		4
Diabetes		4
Suicide—carbolic acid 1, drowning 1, hydrocyanic acid 1, jumping from roof 1		4
Diarrhea		3
Drowned		3
Scarlet fever	63	3
Septicemia		3
Measles		3
Heart prostration		3
Anemia 3, obstruction of bowels 3, congestion of lungs 2, dysentery 2, ulceration of stomach 2, Coroner's cases 2, whooping-cough 2, alcoholism 1, atheroma 1, aneurysm of aorta 1, burns and scalds 1, cyanosis 1, erysipelas 1, gastric fever 1, gangrene 1, hemorrhage of stomach 1, influenza 1, insanity 1, arterial sclerosis 1, stricture of throat 1		

NEW YORK.

New York Medical College for Women.—The late Mrs. Schley, sister of ex Governor Flower, bequeathed \$10,000 to this institution.

To Cleanse Chinese Quarters.—The Board of Estimate has appropriated \$20,000 for the Board of Health to use in fumigating the Chinese quarters in Manhattan, Brooklyn, and Coney Island.

Brooklyn Water Supply.—The shortage in Brooklyn's water supply is growing serious. The reserve supply in the storage reservoirs is at present less than half what it was in June of last year, and, according to the department, there is no relief in sight.

Outings for Poor Women and Children.—The first day excursion of the New York Association for Improving the Conditions of the Poor was sent to the seashore June 26. The association will have 5 such excursions each week until September 1. The average number taken is about 350.

Physicians Speculate.—A well known New York oculist, entering as a silent partner in a firm last January, put in \$200,000. Result, a total loss, the firm failing for \$500,000. Another specialist lost \$25,000 several times on Wall Street; he is now dealing in real estate along the Jersey Atlantic Coast. Some years ago a specialist lost two fortunes in patents and is now too old to make another.

A Novel Life-Insurance Complication.—When Howard C. Benham, of Batavia, was under sentence of death for the murder of his wife he held a life-insurance policy of \$6,000, and the company not desiring to carry a risk on its books of a man who had been executed, paid the policy in full. On the 21st, Benham, having obtained a new trial, was acquitted and is a free man. What action the company will take in the case has not yet been determined.

Life Insurance and Tuberculosis.—Local doctors admit that they have been reporting the secondary cause for deaths occurring as a result of tuberculosis for the purpose of obliging parents with marriageable daughters, and to enable relatives of the victims to pass examinations for life insurance. Insurance officials generally will share with the New York Health Department the anxiety caused by the discovery, that there has been great laxity in the matter of reporting cases of tuberculosis.

Health Commissioner Accused.—Effort is being made to remove Dr. W. T. Jenkins from his position as Health Commissioner, on the ground that he is using his official position for private gain. A long list of charges was presented to the Mayor and sworn to by Dr. Willard P. Worster. According to Dr. Worster, in 1896 Dr. Jenkins organized and had incorporated for his own benefit a society known as the "Merchant Marine Hospital Service and Dispensary" and represented to ship-owners that he will favor their crews through his office. Dr. Jenkins denies the charges and says his connection with the hospital began when he held no official position, and that one member of a board of 5 commissioners could have no power which could be used.

NEW ENGLAND.

The Caney Hospital of Boston received \$25,000 by the will of Julius Adams of that city.

Harvard Medical School.—Dr. Franklin Dexter has been appointed associate professor of anatomy.

The **Harvard Medical School** graduated 135 students this year, 51 of whom received their degree *cum laude*.

Yale University.—M. E. White, professor of pathology has resigned and will be succeeded by Charles Bartlett.

Tetanus.—Four cases of tetanus resulted in Boston from the use of explosives in celebration of Bunker Hill Day, June 17.

The Boston School Committee has passed this order: "Hereafter all school furniture purchased for new, permanent schoolhouses shall be adjustable."

Charles Sedgwick Minot, of Harvard Medical College, has been elected president of the council of the American Association for the Advancement of Science.

Members of the Profession Honored.—The degree of LL.D. has been given to Dr. William Henry Welch, of Johns Hopkins, by Harvard and to Dr. Lewis A. Stimson, of Cornell Medical School, by Yale.

Republican Convention.—Dr. John F. Hill, of Augusta, Me., was nominated for governor this week by the largest Republican Convention ever gathered in the State. The Republican majority is so large that this nomination virtually guarantees an election.

School Sanitation.—More than \$500,000 is necessary to repair 100 school buildings in Boston which according to the Board of Health are in a dangerously unsanitary condition. Were they private property the Board would order their immediate repair or condemnation.

The Boston Floating Hospital made the first trip of the season on July 5. The trips will be taken daily until September 1. The hospital capacity has been increased so that 3 wards, including 55 beds, are available for permanent patients. All day patients who may be sent can be accommodated.

Free Baths for Lowell.—Free public baths received considerable attention in the Lowell city council meeting on June 26. It was said that if the Coburn land, near City Hall were purchased, enough money would be raised by popular subscription to erect a building, and that the Locks & Canal Company would furnish water free.

A Medical Leader.—In conferring the honorary degrees of LL.D. upon Dr. William H. Welch, of Johns Hopkins University, President Eliot used the following words: "William Henry Welch, Professor of Pathology, Johns Hopkins University, who holds first place in the medical profession of the United States as teacher, pathologist, and organizer of medical progress."

Question of Clean Ice.—Dr. Hill, bacteriologist of the Board of Health, of Boston, has been making a personal investigation of the sources of supply of ice companies, with special reference to instances of pollution. Thus far the general condition has been found satisfactory. The Board reserves the right to refuse to let the ice from any polluted pond be sold in Boston.

Appropriation for Newton Hospital.—An order was passed recently by the Newton Aldermen appropriating \$35,000 for two new contagious wards at the Newton Hospital. It was stated that, at one time during the winter, the diphtheria ward was so crowded that 3 patients were placed in one bed, and that it was often the case that a patient having scarlet fever contracted diphtheria in addition, so impregnated with germs were the present wards.

The Harvard Medical School Association.—At a meeting on June 27, it was announced that after next year only college graduates will be admitted to the school, and the medical, dental and veterinary schools shall be merged into one department, under the guidance of a single body of trustees. For the use of this department 26 acres of land have been purchased by a syndicate and the university will buy it as soon as possible. The Apostle of the new methods in medical education was the subject of an address by William T. Councilman. He criticised present methods of teaching and favored 4 examinations a year rather than one. Clarence J. Blake, of Boston, was elected president of the association.

CHICAGO AND WESTERN STATES.

Rush Medical College.—Dr. Henry Favill has been appointed Professor of Therapeutics.

Chicagoan's Charitable Bequests.—The late T. B. Blackstone willed \$2,500 to the Passavant Hospital, \$2,500 to the Relief and Aid Association, \$2,500 to the Orphan Asylum, and \$25,000 to St. Luke's Hospital.

Child Labor.—The State officers of Wisconsin are rigidly enforcing the child labor law. Assistant Inspector J. J. Williams recently visited the large cities and took over 200 children from their employment and caused 18 arrests. The parents are the ones who wilfully violate the law.

Quarantine Raised in Honolulu.—A telegram was received in San Francisco June 21 from Surgeon General Wyman of the Marine-Hospital Service at Washington, D. C., to be forwarded to Assistant Surgeon Carmichael of the Marine Hospital Service at Honolulu, directing that official to suspend all further quarantine against ships clearing from San Francisco, and in addition directing Dr. Carmichael to cease the fumigation of vessels hailing from that port.

Advertising Medicos Left Victim Penniless.—The dead body of Andrew Anderson was found in a well on the grounds of the McLean Hospital, San Francisco, on June 23. In his clothing were found two receipts, one for \$500 and another for \$30, given by a "medical" firm of advertising "specialists" in acknowledgment of his payment to them for treatment for an incurable disease. He is supposed to have committed suicide because of having been left penniless through this extortion.

A Novel Idea.—A physician in Chicago has provided for himself and family a noise-proof house as a protection against the street dins, which persist despite the recently announced intention to enforce the anti-noise ordinance. The problem was to exclude the noises and admit the air, and he solved it, he says, by stuffing all the cracks about the doors and windows with strips of rubber, perforated with zigzag holes. Through these air is admitted while the noise is deadened, the sound waves dying out in repeated reflections in the crooked passages.

The Ohio Medical Law.—A law governing the license to practice has recently been enacted in Ohio, similar to that of Pennsylvania and New York. It contains a reciprocity clause authorizing the registration of certificates issued by other States that enforce equally high requirements. The examinations shall be conducted under the direction of the State Board of Medical Registration and Examination, and shall be held simultaneously in Cincinnati, Cleveland, Columbus, and Toledo, the questions being the same at each place. The leading medical sects are all represented in one board. The osteopaths succeeded in securing a provision to the effect that the law should not apply to anyone of their craft holding a diploma from a legally chartered and regularly conducted school of osteopathy issued on the requirement of four annual five-month terms, provided he passed an examination by the board in anatomy, physiology, chemistry and physical diagnosis; but that he should not be permitted to administer drugs or perform major surgical operations. They failed to obtain the enactment of a bill providing for a State Board of Osteopathic Examiners with power to pass upon the qualifications of those who wish to practice that peculiar system of massage.

Diploma-Mill Men in Jail.—After 4 years of defiance of the State Board of Health of Illinois, the proprietors of the Metropolitan Medical College of Chicago have been arrested by United States Marshals on the charge of using the mails to defraud. The 4 members arrested and held in default of bail are: James Armstrong, president of the college, J. H. Randall, vice-president, Thomas Armstrong, secretary, and Charles M. Hovey, attorney. Complaints have come from all parts of the United States and Europe about the bogus diplomas, and many of the graduates are said to be practising in India. Texas is the home of many of those remaining in the United States. The diploma mill called the Metropolitan Medical College is a successor of the Independent Medical College which in turn had been a successor of the Illinois Health University. The State Board of Health with the assistance of the Governor of the State succeeded in passing a bill in 1899 which gave the attorney-general power to end the operation of such institutions. Learning that the promoters of the "college" were in possession of several additional charters under which they expected to conduct business as soon as the courts should deprive the Metropolitan of its power to issue degrees, the Board thought it best to place the proof obtained in the hands of the postal authorities. Inspector Guy T. Gould matriculated as a student and was expected to attend for about 10 days, but his advanced knowledge in the science of medicine was accepted by the faculty to warrant his being graduated in 3 days. The inspector in the course of a quiz was asked, "What would you do in a case of appendicitis?" "I'd get a doctor," he replied. "Well, you're all right," said the lecturer, "I think we can graduate you at once."

SOUTHERN STATES.

Johns Hopkins University.—Dr. F. S. Cullen and Dr. W. W. Russell have been appointed professors of gynecology.

The Kentucky School of Medicine.—At the annual commencement exercises of the Kentucky School of Medicine the doctorate address was delivered by Dr. Roswell Park, LL.D., of New York. Degrees were conferred upon 49 graduates, 14 of whom are postgraduates. The school is a direct descendant of the medical department of the Transylvania University.

Orleans Parish Medical Society.—At a meeting June 23, Dr. E. H. WALET reported a case of **Carbuncle of neck**, complicated with phlebitis and metastatic abscesses, exhibiting patient. DR. S. P. DELAUP made a preliminary report of a case of **Ligation of the innominate artery**. The patient is a male negro, 57 years of age, married, laborer. Six years ago he suffered an attack of apoplexy which confined him to bed a month, the left side being paralyzed. General arterial sclerosis is present. Aneurysm was first noticed by patient about four months ago. Idiopathic aneurysm of third portion of subclavian artery was diagnosed. At the operation (June 14) another aneurysm was discovered at the bifurcation of the innominate and common carotid arteries. Three ligatures were applied to innominate artery—one-fourth of inch apart—2 of kangaroo tendon and 1 of corded silk. Pulsation reappeared in the tumors and at the wrist in 3 hours. The patient is now doing well.

CANADA.

University of New Brunswick, Fredericton.—At the recent centenary celebration the degree of Doctor of Laws was conferred among others upon the following members of the McGill University, Principal Peterson, Dr. A. Johnson, Dr. J. G. Adams.

Improvements at McGill University.—The enlargement of the present medical buildings at McGill is soon to become an accomplished fact. In order to interfere as little as possible with the work of teaching, it is intended to spread the repairs and improvements over a period of about 2 years. The changes contemplated were rendered possible by a donation of \$100,000 from Lord Strathcona and the Hon. Mrs. Howard, and will afford a much needed increase in accommodation.

Epidemic Smallpox.—During the past few months there has been an epidemic of smallpox in the province of Quebec and some few cases have developed in Montreal. Fortunately the measures adopted have been successful and the disease has been practically stamped out. About 500 cases altogether were found in Canada, 230 of which were in the province of Quebec. The type of the disease seems to have been the same as that of the epidemic occurring in the Central States. While it was very mild the infectivity seems to have been very great. The similarity to chickenpox was marked. Secondary fever rarely recurred. The eruption passed through all the typical stages, but dried up quickly.

Montreal Medico-Chirurgical Society.—At a meeting held June 22, Dr. JAMES STEWART showed an interesting case of **ankylosis of the cervical vertebra** due to old gonorrheal inflammation. DR. ADAMI and JAS. BELL reported a very interesting case of **actinomycosis of the liver**. The patient was a farmer, aged 22. He had suffered for some weeks from irregular fever with, at intervals, expectoration of large quantities of very fetid pus. In the sputum no tubercle-bacilli were found. It was thought an empyema was present and aspiration of the chest was performed without result. Then the chest was opened, and on the upper surface of the diaphragm a white fungating mass was discovered, but no pus. The patient subsequently died, and at the autopsy, in the right lobe of the liver and extending from it down through the diaphragm, was found a large mass the size of an orange. In the pus from this area, the actinomycetes were readily demonstrated. Multiple foci were also found in the lungs, spleen, and kidneys. The case deserves importance, as it is probably the first case reported in

Canada. DR. G. E. ARMSTRONG read a paper on **Gastric ulcer** in which he reviewed the statistics of Keen and of Welch as to its site and frequency. The ulcer was most often found on the anterior surface near the cardiac and the lesser curvature. Under the most recent methods the mortality has been decreasing as the condition has been more promptly recognized of late by physicians. The rapid occurrence of a board-like resistance of the abdominal muscles was emphasized as a very important diagnostic feature.

McGill University.—The 67th annual session of the Medical Faculty came to an end on June 15. The total number of students in the faculty was 469. The graduating class numbered 95, of whom 75 received the degree of Doctor of Medicine. An interesting feature of the session was the inauguration of a Course in Public Health for graduates, this being the first course of the kind to be given in any university in America. The course embraced sanitary chemistry, bacteriology, chemical analysis, hygiene, and similar subjects. The course was intended to qualify its diplomates for the duties of public health-officers. At the convocation the diploma of Public Health was conferred upon Drs. W. W. Ford, J. E. Laberge, H. S. Shaw, and J. Allan Williams. The following promotions have been made in the Faculty: Dr. A. G. Nicholls to be lecturer in pathology; Dr. S. W. Stirling, lecturer in ophthalmology; Dr. D. J. Evans, lecturer in obstetrics; Dr. J. N. McCarthy, lecturer in anatomy.

MISCELLANY.

Yellow Fever Subsiding.—No new cases are reported at Quemados. All the nonimmunes are now confined in the detention camp at Mirianao. At Santa Clara there have been no cases since the troops left the city.

Obituary.—GEORGE S. WARD, of Newark, June 26, aged 73.—SAMUEL C. LUCHSINGER, of Milwaukee, June 23, aged 28.—GEORGE GODFREY SANE, of Madison, N. J., June 25.—LLOYD MORRIS HORWITZ, of Helena, Montana, June 22, aged 33.—J. T. M. CARDEZA, of Claymont, June 28, aged 80.—CARTER GRAY, formerly professor of neurology in the Long Island College Hospital, Brooklyn.—DR. FROTHINGHAM, late professor of ophthalmology in the Ann Arbor University, Michigan.—LOUIS ARCULARIUS, of New York, July 1, aged 62.—FESSENDEN NOTT OTIS, of New York, aged 75.

Condescension to the Educated Profession.—The Secretary of the State Board of Medical Examiners, in accordance with the action of the Twenty-eighth General Assembly, Iowa, holds the examination for medical certificates at the colleges. The reduction of the fee from \$20 to \$10 for examinations before the Board is also greatly appreciated. While the generosity of the people and of the Legislature allows the Faith Healers, Christian Scientists, Magnetic Healers, Weltmerites, Chiropractics and Five-yearites to practise without certificates or the annoyance and expense of examination or of previous medical study, the physician appreciates the concessions above referred to as granted by the late General Assembly.—*Iowa Health Bulletin*.

The International Medical Congress.—According to instructions from Dr. A. Chauffard, Secretary-General of the thirteenth International Medical Congress, no subscriptions to the Congress will be received after July 15, and the name of no subscriber will appear in the official program whose subscription was not received before June 15.

The publications of the Congress will consist of 17 volumes, one of which will be sent gratuitously to each subscriber; that is, the volume containing the papers of the section under which he has inscribed himself. The other 16 volumes may be purchased at 4 francs a volume, or 45 francs for the series.

Cuban Improvement.—Surgeon-Major Reed and Drs. Carroll, Agramonte, and Lazcar, the commission recently appointed by Secretary Root to investigate acute infectious diseases in Cuba, have begun operations at Quemados, where several cases of yellow fever have occurred during the last few weeks. The conservative portion of the local press heartily approves of the project. Besides yellow fever, they will investigate leprosy, acclimating fever, malaria, and, in

fact, everything infectious. The yellow-fever situation at Quemados shows much improvement. There have been only four deaths, two of which were Americans, including Major Frank H. Edmunds, acting inspector-general on the staff of General Fitzhugh Lee, who died June 18. General Lee refuses to leave his headquarters, though he has given permission to his staff if they desire to do so.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended June 29, 1900:

Changes in the Medical Corps of the U. S. Army
for the week ended June 30, 1900:

STONE, First Lieutenant J. HAMILTON, assistant surgeon, now on temporary duty at Santa Clara, Cuba, is relieved from all duty with the garrison at Matanzas, and assigned to station at Santa Clara Barracks, Santa Clara, Cuba.

McLAUGHLIN, W. B., acting assistant surgeon, will proceed from Matanzas to Sagua Barracks, Sagua-la-Grande, Cuba, for duty.

FORSYTHE, J. W., acting assistant surgeon, is relieved from duty at Sagua Barracks, Sagua-la-Grande, Cuba, will proceed to Matanzas, Cuba, for duty.

ECHEVERRIA, Major RAFAEL, surgeon, relieved from duty as attending surgeon to quartermaster's employes, and will report to the commanding general, department of Havana and Pinar del Rio, for temporary duty.

DUCKER, Major ORLANDO, surgeon, is relieved from special duty in the office of the chief surgeon of the division of Cuba, and will report to the commanding general, department of Havana and Pinar del Rio, for temporary duty.

BARNET, E. B., acting assistant surgeon, in addition to his present duties, will attend the quartermaster's employes at the Corral, Havana, Cuba.

BALCH, Major LEWIS, surgeon, the orders of June 15, honorably discharging him from the service is revoked.

ANDERSON, CHARLES, acting assistant surgeon, will proceed from Santa Barbara, Cal., to Fort Brown, for duty.

CROSBY, Major WM. D., surgeon, U. S. Volunteers, captain and assistant surgeon, U. S. Army, is honorably discharged from the volunteer service, only, to take effect June 30.

DEVEREUX, JOHN R., acting assistant surgeon, now in Washington, D. C., will report at Washington Barracks for duty.

NOEL, AUGUSTE A., acting assistant surgeon, will proceed from New York City to Havana, Cuba, and report to the commanding general, division of Cuba, for assignment to duty.

CRABTREE, GEORGE H., acting assistant surgeon, will proceed from Chicago, Ill., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

WOLFE, First Lieutenant EDWIN P., assistant surgeon, is relieved from duty at Puerto Principe, Cuba, and will proceed to Morro Castle, Santiago de Cuba, for duty.

DAY, JAMES L., acting assistant surgeon, now at Vancouver Barracks, will proceed with the necessary medicines to Seattle, Wash., for duty on the transport "Egbert."

POLHEMES, Captain ADRIAN S., assistant surgeon, is granted leave for 7 days, to take effect after the completion of his duties as medical officer accompanying detachment of the Sixth Cavalry to San Francisco, Cal.

TAYLOR, RALPH L., acting assistant surgeon, is granted leave for one month, subject to his recall by telegraph in case his services are needed.

HARVEY, Major PHILIP F., surgeon, leave granted is extended one month.

A board of medical officers to consist of Major JOHN VAN R. HOFF, surgeon; Major PETER R. EGAN, surgeon; Captain GEORGE M. WELLS, assistant surgeon; First Lieutenant FREDERICK F. RUSSELL, assistant surgeon, is constituted to meet at headquarters, department of Puerto Rico, San Juan, P. R., for the examination of candidates for admission into the medical corps of the Army.

GIESCHING, FRED, hospital steward, now at the Post Hospital, Presidio, from the division of the Philippines, will be sent to Fort D. A. Russell for duty.

BUNGER, HENRY, hospital steward, is relieved from duty at Fort D. A. Russell, will be sent Manila, P. I., for assignment to duty.

Changes in the U. S. Marine-Hospital Service,
for the week ended June 28, 1900:

AUSTIN, H. W., surgeon, granted leave of absence for 1 month from August 2, 1900.

MAGRIDER, G. M., surgeon, granted leave of absence for 10 days.

SMITH, A. C., passed assistant surgeon, granted leave of absence for 7 days.

OAKLEY, J. H., passed assistant surgeon, granted leave of absence for 15 days.

SPRAGUE, E. K., passed assistant surgeon, granted leave of absence for 10 days.

WICKES, H. W., passed assistant surgeon, granted leave of absence for 15 days.

GEPPES, S. B., assistant surgeon, granted leave of absence for 1 month from August 20.

ANDERSON, F. F., assistant surgeon, granted leave of absence for 10 days.

BILLINGS, W. C., assistant surgeon, granted leave of absence for 15 days from June 28.

WILSON, R. L., assistant surgeon, relieved from special temporary duty at San Francisco Quarantine, and directed to report to the medical officer in command at San Francisco for duty and assignment to quarters.

EARLE, B. H., assistant surgeon, is relieved from special temporary duty at San Francisco Quarantine and directed to report to the medical officer in command at San Francisco for duty and assignment to quarters.

LONG, J. D., assistant surgeon, upon being relieved from duty at New York, N. Y. (Stapleton), is to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for duty.

FRANCIS, EDWARD, assistant surgeon, will proceed to New York, N. Y. (Stapleton), and report to the medical officer in command for duty and assignment to quarters.

BAHRENBURG, L. F. H., assistant surgeon, will proceed to New York, N. Y., and report to Surgeon L. L. Williams, Immigration Depot, for duty.

BURKHALTER, J. T., assistant surgeon, to proceed to New York, N. Y. (Stapleton), and report to medical officer in command for duty and assignment to quarters.

BOGGESE, JOHN S., assistant surgeon, to proceed to Chicago, Ill., and report to medical officer in command for duty and assignment to quarters.

MC COY, G. W., assistant surgeon, to proceed to St. Louis, Mo., and report to medical officer in command for duty and assignment to quarters.

PIERCE, C. C., assistant surgeon, to proceed to Mobile, Ala., and report to medical officer in command for duty and assignment to quarters.

WARREN, B. S., assistant surgeon, to report at Washington, D. C., for temporary duty.

ROWLES, J. A., acting assistant surgeon, granted leave of absence for 10 days from June 12.

SIBREE, H. C., acting assistant surgeon, granted leave of absence for 7 days.

ROEHRIG, A. M., hospital steward, upon being relieved from special temporary duty at the San Francisco Quarantine, to rejoin station at San Francisco, Cal.

HANRATH, F. R., hospital steward, relieved from duty at New York, N. Y. (Stapleton), and upon expiration of sick leave of absence, to proceed to Cleveland, Ohio, and report to medical officer in command for duty and assignment to quarters.

GIBSON, F. L., hospital steward, relieved from duty at Washington, D. C., and directed to proceed to Honolulu, Hawaii, and report to Surgeon D. A. Carmichael, for duty and assignment to quarters.

APPOINTMENTS.

EDWARD FRANCIS, of Ohio, LOUIS P. H. BAHRENBURG, of Ohio, JOHN T. BURKHALTER, of Georgia, JOHN S. BOGGESE, of Ohio, GEORGE W. MC COY, of Tennessee, CLAUDE C. PIERCE, of Tennessee, and BENJAMIN S. WARREN, of Alabama, commissioned as assistant surgeons, June 22.

WALTER R. HICKS, of Michigan, appointed acting assistant surgeon, for duty at Menominee, Mich., June 23.

Changes in the Medical Corps of the U. S. Navy, for the week ended June 30, 1900:

FISKE, C. N., assistant surgeon, ordered to the Boston Navy Yard, June 22.

RUSH, W. H., surgeon, when discharged from treatment at the Naval Hospital, Mare Island, Cal., ordered to Washington, D. C., July 10, for examination for retirement, and then home and to wait orders.

EAKINS, O. M., assistant surgeon, detached from the "Buffalo," and ordered to the "Scindia."

STOKES, C. F., surgeon, promoted to surgeon from May 31.

Bacteriologic and Clinical Researches with Reference to Slight Elevations of Temperature during the Puerperium.—Franz (*Obstetrics*, May, 1900, translated from the *Centralblatt für Geburtshilfe und Gynäkologie*) has studied a series of 2,285 cases of labor, and from his clinical researches has undertaken to answer the following questions: 1. Is there any relation between the number of fever cases, and primiparity, multiparity, duration of labor, time at which the membranes are ruptured, duration of the stage of expulsion, and duration of the third stage? 2. What conclusions, positive, or at all events, probable, with reference to the origin of the bacteria, can be drawn from the omission of internal examinations, the number of examinations, the number of examiners, and the number of operations? These questions he answers in the following resumé: 1. Slight elevations of temperature during the puerperium are usually caused by saprophytes which gain access to the uterine cavity. 2. The saprophytes themselves do not cause fever. It develops only when the outflow of the bacteria-containing secretion is prevented. 3. The saprophytes which are found in the uterus in cases of slight elevation of the temperature are probably identical with the saprophytes of the vagina. 4. Internal examination is usually a factor in causing slight elevations of temperature, only in so far as it causes vaginal wounds which serve to further the development of the bacteria which are always present. 5. Slight elevations of temperature occur oftener by half in primiparas than multiparas. 6. Diminishing the duration of the third stage increases the number of slight elevations of temperature. 7. Long duration of labor, long duration of the expulsive stage, and premature rupture of the membranes, have but little influence in producing these cases. [W. K.]

foreign News and Notes.

GREAT BRITAIN.

The Royal Society is about to elect as a member Dr. Patrick Manson, physician to the colonial office.

University of Dublin.—Sir William MacCormac received the degrees of M.D., M.Ch., *honoris causâ*, in the University of Dublin, June 23.

Royal College of Surgeons of England.—John H. Morgan has withdrawn his name from the list of candidates for a seat on the Council of the Royal College of Surgeons of England, J. A. Bloxam, senior surgeon to Charing-cross Hospital, having decided to become a candidate.

The Howard Medal.—The subject for the essays for the Howard Medal of the Royal Statistical Society, to be awarded in 1901, with £20 as heretofore, is the History and Statistics of Tropical Diseases, with especial reference to the bubonic plague. The essays should be sent in by June 19, 1901.

Epsom College.—On June 16, the Council of Epsom College awarded the Wakley prize to the Senior Prefect Colin Giffard. The prize is the result of a collection made by the friends of the late Thomas Wakley. The amount collected was invested and the dividends provide the funds for the prize, in perpetuation of the memory of the founder of the *Lancet*.

The Late Mrs. Gladstone.—To the late Mrs. Catherine Gladstone the medical profession owes a great debt in that she was the pioneer of the free convalescent home movement. The distress caused by the cholera epidemic of 1866 forced upon her attention the necessity of such institutions. She appealed to the public, and generous donations were sent in, including one of £1,000 from the Queen. The first home was opened at Snaresbrook, later transferred to Woodford.

Irish University Education.—At the annual meeting of the Assembly of the Presbyterian Church in Ireland, held in Dublin June 8, the convener of the Committee on Higher Education strongly commended as an equitable solution of the university question the nationalization of Trinity College, by which is meant that the theological degrees, as well as the degrees in medicine, law, and art, should become the property and privilege of the whole nation.

The Council of the Children's Country Holiday Fund has sent in one year over 33,000 children from the slums of London into the country for a fortnight's holiday. Mr. Treves attended the recent annual meeting of the subscribers to the fund, and is reported to have said that unless means could be devised whereby London children could from time to time see something of the country, he was afraid the condition of these children would never improve.

The Thames Conservancy.—The general report of the conservators of the river Thames for the year 1899 has recently been published. Probably none of the public bodies engaged in work bearing on the health of the people of London carries out the duties committed to it with more thoroughness than this Board. Few realize that the purification of the river is only one of the important duties which they have to perform, a great part of their work being the protection of the navigation of the river, both above and below London.

The officers of the Indian Medical Service held their annual dinner at Hotel Cecil, London, June 14, under the chairmanship of Sir Trevor Lawrence. After the usual loyal toasts had been proposed and honored, that of the "Sister Services" was given by Surgeon-General C. Sibthorpe, Sir Henry Noobury and J. Jameson responding. The Chairman proposed the toast of "The Guests" to which W. S. Church responded. The President of the Medical Society of London, Frederick Roberts, proposed "The Indian Medical Service," to which Sir Joseph Fayrer replied, referring to the early days of the service and the influence of Broughton and of Hamilton.

National Sanatorium for Consumption, Bourne-mouth.—The report presented to the annual general meeting of governors of this institution showed that there was a debt of £655 for the building of a new sanitary wing at a cost of £1,000, and that the ordinary annual expenses had been increased to the extent of about £200, due mainly to the expenditure requisite for efficiently carrying on the open-air treatment, and that this further sum would be required to meet the expenses of the present year.

Disease in South Africa.—The death of 538 men and 20 officers in the South African Field Force is reported for the fortnight ended June 9. The *Times* publishes daily detailed lists of the victims to disease. The report for the 6 days ended June 16 is typhoid fever 188, dysentery 13, pneumonia 5, various diseases 10; total 216. A disease in epidemic form called "veldt fever" is reported, which is attributed to infection from dead horses. The symptoms are those of ordinary epidemic influenza, and it is probably an old disease under a new name.

The World's Temperance Congress.—The British Medical Temperance Association recently entertained the scientific members of the World's Temperance Congress. The *Physician and Surgeon* believes that the methods of temperance reformers in general, and Dr. Ridge and Mr. Horsley in particular, can never achieve the ends they have in view. Dr. Archdall Reid declares that every scheme of temperance reform—total prohibition, local veto, the Gothenburg system, etc.—which depends on the abolition or diminution of the alcohol supply, is in effect a scheme for the promotion of ultimate drunkenness.

The Omagh (Ireland) Board of Guardians have referred a case of interest to medical officers, of Poor Law and other administrative bodies, to the Local Government Board. Dr. Hunter, of Carrickmoore, was summoned to give evidence in a case in Dublin. The call was imperative, and he felt himself justified in repairing to Dublin without first asking the consent of the Board of Guardians, whose medical officer he was. The liability for paying the fee of the *locum tenens* thus devolved on the guardians, they having through their relieving officer appointed a substitute. They allege that before leaving his dispensary derelict, Dr. Hunter was bound to apply to them for leave of absence, and they would have granted permission only on the condition that he provided and paid a substitute.

Overcrowding in London.—The recent debate in the House of Commons on a Government bill for the housing of the working classes revealed a very bad state of affairs, notwithstanding all that has been done. The London County Council has rehoused 8,928 persons, displacing 16,615, but meantime London rents have doubled with a fearful strain upon workmen's means. Statistics showed 900,000 persons living in an illegally crowded condition. In Camberwell 17 persons were found living and sleeping in one room. In the East End beds were let out to 3 sets of occupants daily, for 8 hours each. The Public Health Act forbids this; but it was said, "Of what use is it to eject from houses those whose only other sleeping-place is the Thames Embankment under the open sky?" The death rate from contagious diseases has gone up in the last 30 years from 101 and 160 to 270 to the 1,000. The bill authorized a County Council to provide houses outside of its own district—it being found impossible to rehouse in London, so long as slum property has to be bought up on the greedy owner's terms. Meanwhile the expense to the taxpayers of hospitals and other reliefs for the victims of overcrowding is said to be \$650,000 a year.

The Royal Society Annual Conversazione.—The exhibition held by the Royal Society on June 20 contained little of a novel character, yet fully maintained the high standard it has reached in recent years. An apparatus for the production of short electric waves and the study of electro-optic phenomena was shown by Dr. J. A. Fleming. A beam of electric radiation was produced by a radiator, the wave-length being about 3 inches. The receiver is of the Branly type and is connected with a relay and an electric bell to indicate the impact of electric waves. The spectra of the inert gases of the atmosphere were exhibited by Prof. W. Ramsay and Dr. M. W. Travers, who have now succeeded in

thoroughly separating 5 constituents from atmospheric nitrogen, viz., helium, neon, argon, krypton, and xenon. Dr. William J. S. Lockyer showed some clever photographs of bright and dark lightning flashes. The poisonous lotus of Egypt was shown by Prof. Wyndham Dunstan. This plant is very poisonous to animals in its living condition, but when dried becomes a useful fodder. Experiments were performed by Prof. Hele-Shaw and Mr. Hay on stream-line motion analogous to lines of magnetic induction. Two models of mosquitos enlarged 23 times linear and models of human blood-corpuscles infested with the malaria parasite were shown by Prof. E. Ray Lankester.

CONTINENTAL EUROPE.

The Health of Paris.—An epidemic of typhoid is now raging in certain parts of Paris. The average number of cases reported in 4 years, 1895-98, was 1,315. In 1899 the number rose to 4,329 of which 398 were reported in the first 10 weeks. During the same period of 10 weeks in 1900 no less than 891 were reported. The cause has been traced by Drs. Thoinot, Martin, and Miquel to that portion of the water-supply derived from the River Vanne. It is said that the desire to keep these facts from being too well known resulted in Dr. Thoinot being removed from his office.

Physician Declined Challenge.—A physician at Freiburg recently had an altercation with one of his confrères. When provoked by the latter he declined to challenge him, alleging religious scruples. As each happened to be surgeon-major of reserves the military tribunal took up the case with the result that the physician who declined to fight has received the following order from the Emperor's cabinet: "You are dismissed from your rank as surgeon-major of the reserves, because, in spite of repeated invitations, made to you in demand, in conformity with the laws of honor, reparation for an insult, you have refrained from challenging your adversary."

University Appointments.—WÜRZBURG: Professor Hess of Marburg has been appointed to the chair of ophthalmology, vacated by the migration of Professor von Michel to Berlin.—ZÜRICH: Dr. Paul Ernst of Heidelberg has been appointed professor of pathology and general anatomy.—KÖNIGSBERG: Dr. Oscar Santer, *privat-docent* of surgery, has been made professor.—PRAGUE (Bohemian University): Dr. Kunta has been promoted to an extraordinary professorship of pathological anatomy; Dr. Carl Kuffner has been appointed professor of psychiatry and neuropathology.—GÖTTINGEN: Dr. A. Cramer has been appointed to the chair of psychiatry.—HEIDELBERG: Dr. Göppert has been appointed extraordinary professor of anatomy.—INNSBRUCK: Dr. Stephan Bernheimer of Vienna has been appointed professor of ophthalmology.

Alcoholism in Primary Schools.—The German authorities at Bonn, according to the *Medical Age*, had an investigation upon alcoholism among pupils in the primary schools, which shows a startling state of affairs. Out of 100 children, 16 did not drink milk, and absolutely refused to drink it because it had no savor. Of 237 pupils, 7 to 8 years of age, there was not one who had not drunk wine, beer, or whisky, although 23% had never tasted whisky, but habitually drank beer or wine. Of these children, 8% were given their glass of whisky every day by their parents that they might become strong. As a result of these investigations it was proved that children most accustomed to alcohol showed the least intelligence; children who had their morning glass of whisky and found no savor in milk showed it by great inattention during the morning hour. A curious fact shown by this investigation was that young girls who took whisky with their breakfasts were more numerous than young boys.

Experimental Treatment of Tuberculosis by Means of Raw Meat and Meat-Juice.—M. Richet and M. Héricourt, of Paris, according to the *Lancet*, inoculated a certain number of dogs with tuberculosis and separated them into 3 groups. The dogs composing the first group were fed upon ordinary food and died at the end of 3 or 4 weeks. Those in the second group were fed upon cooked meat and lived very little longer than did those in the first

group. Those in the third group were fed solely upon raw meat and remained in perfectly good health at the end of 6 months from the beginning of the experiment. The curative influence which a raw meat diet possesses over tuberculosis experimentally produced in dogs is thus established, for it is almost unknown for a tuberculous dog, living under ordinary conditions, to last for more than 3 months. Raw meat-juice appears to have the same action as that of raw meat. M. Richet and M. Héricourt have also ascertained that this effect of raw meat has a prophylactic as well as a curative action. Two dogs which had been fed for many months upon raw meat and meat-juice were inoculated and are alive at the present moment, despite the fact that after the inoculation they were taken off the special diet and put upon ordinary diet. Control dogs inoculated at the same time, but which had not been prepared by being fed upon the special diet beforehand, are dead long ago. The two observers have also investigated the dose necessary to obtain success, and consider that to preserve a dog from the effects of an inoculation of tubercle it must be given a minimal dose of from 10 to 12 grams to the kilo of body-weight every day. The active principle is evidently a soluble substance, for if the meat is chopped up and pressed to deprive it of its juice, a second pressing after moistening with water produces an absolute inactive fluid, even after the meat has been allowed to soak for 24 hours. These facts confirm the results formerly obtained by Malassez and Vignal who laid stress upon the importance of muscular "opotherapy" in tuberculosis. They had noticed that tubercle never developed in muscles and concluded that meat-juice contained some plasma inimical to the evolution of tubercle.

MISCELLANY.

Surgeon-General Y. Saneychsi, of the Imperial Japanese Navy, has been made a Baron.

Obituary.—THOMAS JONES, of Manchester, died at Springfontein.—ALFRED FISHER, of Liverpool, June 17, aged 37.—FRIEDRICH BROSN, of Dresden, aged 42.—WILHELM KÜHNE, of Heidelberg.—EDWARD MATTHEW SHIRTLIFF, of Newlands, aged 63.—PROF. JOSEPH GRUBER, of Vienna, aged 73.

Rains in Famine District.—The Viceroy of India cables that the monsoon has considerably improved the west coast. Six inches of rain has fallen in Bombay City, extending to Berar and the central provinces, while there have been frequent showers in the submontane districts and the north-western provinces.

Dr. Rudolf Amandus Philippi, of Santiago, 92 years of age, will soon celebrate the seventieth anniversary of receiving his doctor's degree from Berlin University. He is professor of botany in the Santiago University, and director of the Natural History Museum. He attended Alexander von Humboldt's lectures when a student.

The Famine in India.—Lady Curzon in a letter to the Famine Relief Committee of Chicago said that \$26,000,000 had been expended in direct relief by the Indian Government, \$10,000,000 in suspensions and remissions of land revenue, 6,000,000 for the purchase of seed and cattle, and \$5,000,000 in loans to the distressed states. The Relief Committee has, through various channels, disbursed \$2,500,000. This is to be met partly by reducing appropriations for military purposes from \$80,000,000 to less than \$72,000,000.

The Colonial Surgeons in Ashanti.—Of the 26 Europeans believed to have been surrounded in Coomassie on the west coast of Africa by the revolted Ashantis, 6 are in the Colonial Medical Service. The victims to duty are Patrick Joseph Garland, Edward Herbert Tweedy, Albert John Chalmers, William Medlycott Graham, J. B. Hay, and W. F. Macfarlane. The climate in which they live is one of the most fatal in the world to white men. At present they are in a critical condition, shut up in a native town far from the sea, with no immediate prospect of relief.

Antityphoid Serum Fails in India.—The experiment with the antityphoid serum in the army is, so far, disappointing, according to the *Medical Press and Circular*. "According to Surgeon-General Jameson, the inoculated officers seem to have suffered in a somewhat larger propor-

tion than the noninoculated, and to have exhibited a higher case-mortality, differing in this respect from the results of inoculation of the men. When, however, they did contract the disease the same high case-mortality was observed as among the officers. It is too early as yet to draw any far-reaching conclusions from this experiment on a large scale."

Fever at Bloemfontein.—The War Office has issued correspondence with Lord Roberts regarding the charges relating to inadequate hospital service at the seat of war. He suggested a committee of inquiry and said there had been an abnormal number of sick at Bloemfontein due to the exhausting march and to the terrible unsanitary condition of the camp at Paardeberg, where the only water available for drinking flowed from the Boer camp where the river contained many decomposing animals. There was also a large number of wounded after the fight on March 10. To accommodate 2,000 was no easy task, said Lord Roberts. No tents were carried and the public buildings had to be turned into hospitals. In 3 months 6,369 enteric fever patients were admitted, with 1,370 deaths—about 21%. If the rate was abnormal it was due to the exhausted state of the men and not to the neglect of the medical corps. The principal medical officer reported that the arrangements at Kroonstadt were in good order.

Rains Scant in India.—The Secretary of State for India received the following dispatch from the Viceroy of India, July 2: "Rainfalls have been fairly general during the past week, but the monsoon current continues weak, causing anxiety. Frequent showers have fallen in parts of the Central Provinces, Mysore, Bombay, the Decca, Madras, Berar, and Hyderabad, but the rainfall to date is insufficient for a general resumption of agricultural operations. Little or no rain has fallen in Northwestern India. In anticipation of the rainy season, work near villages and home gratuitous relief are being largely substituted for the large works, and Government advances are being freely given for the purchase of plows, bullocks, seeds, and subsistence. The poorer cultivators are receiving gifts from the famine fund. Even after abundant rain has fallen throughout the distressed districts, relief will be necessary on a large scale until the early crops ripen. The persons receiving relief number 5,803,000."

The Plague.—The mortality from plague in India generally is declining. Throughout all India only 746 deaths were reported for the week ending June 2, compared with 975 for the previous week. In the city of Bombay 205 deaths occurred from plague, being the largest number in any single town or province of India. Throughout the Bombay Presidency generally, exclusive of the city, 162 deaths from plague occurred. In the city of Calcutta 167 plague deaths occurred during the week ending June 2. June 13 a telegram from Brisbane was received in London to the effect that 2 deaths from plague had occurred there, and 1 death at Rockhampton. There has been no news of plague in South America for some time. It seems, however, that it has been more severe in Rio de Janeiro than the absence of news would have implied, for although it is stated to be declining, there were 27 cases of plague and 13 deaths from the disease during the first week of June, 1900.

Congenital Luxation of the Knee-joint.—Drehmann (*Zt. f. Orthop. Chir.*, vol. iii, 4th part) says that in these cases the capsular ligament is always intact, but is very slack and loose, and the patella is generally smaller and often absent. The conical ligament is stretched, but limits further dislocation of the joint. In 102 out of the 127 cases reported the tibia was displaced anteriorly, and in 54 of the 102 only one side was involved. The etiology of this deformity is explained as follows: early in the fetal life the foot becomes displaced upwards and engages in the chin, axilla or some such place, and is held there so that as the leg grows the joint is overextended, causing a displacement, and finally a slipping of the tibia out of its normal position follows. The prognosis is much more favorable than in cases of congenital hip-dislocation, and if the treatment is instituted early enough a cure should almost always result. The treatment consists in forcibly restoring the parts to their proper place, and fixing the limb in a flexed position for several weeks, at the end of which time healing should result. [G.B.W.]

1.—From a study of the two cases reported in this paper and of the related literature the conclusion is reached that cases of **muscular atrophy** that present the well-known localizations regarded as characteristic of the different forms of muscular dystrophy. In the large majority of these cases the spinal cord and the peripheral nerves are normal. In other rare cases, presenting the clinical features of **muscular dystrophy**, the nervous system is more or less involved. The histologic changes in the muscles are not pathognomonic of any form of atrophy. Muscular dystrophy is to be regarded as a disease usually distinct from spinal muscular atrophy, but transitional forms connect the myopathic and myelopathic types of atrophy.

2.—In the case here reported **degenerated motor fibers** were traced throughout the central nervous system from the Rolandic area into the sacral region. Degeneration was found in the corpus callosum, the ulnar nerve and the muscles of an upper limb, and the degeneration of the cerebral cortex was employed to determine the extent of the cortical motor area in man.

3.—A woman, 63 years old, presenting left hemiplegia, was suddenly seized with symptoms of uremia, which terminated fatally. Postmortem examination disclosed in addition to marked interstitial nephritis, a large, flat tumor of the dura, extending over the right frontal lobe, encroaching somewhat on the motor area and on histologic investigation proving to be an **endothelioma** infiltrating the cerebral tissues. In sections of the cerebral cortex in the neighborhood of the tumor the coats of the vessels, especially the media, were greatly thickened. The ganglion-cells in the regions supplied by these vessels were not arranged normally in layers. Many of them were without nuclei, such of the latter as were present being displaced to the periphery. The cell-processes were few in number and often beaded and fractured, and the apical processes of the large pyramidal cells pointed in various directions. The latter cells presented further the microchemic reactions of **iron-infiltration**.

In a rabbit treated experimentally with rattlesnake venom there occurred rotation about the longitudinal axis of the animal, with arching of the spine, exaggeration of the reflexes and exophthalmos with ocular deviation. After death there were found chromatolysis and pigmentation of nearly all the cells of Purkinje in the cerebellum and slight pigmentation of the motor cells of the cerebral cortex.

From a consideration of the conditions found in these two cases the conclusion is reached that an infiltration of iron, associated with diseased arteries, may occur in ganglion-cells

from childhood to old age. An infiltration of a hemoglobinoid substance in the ganglion-cells is possible in connection with disintegrating processes of free blood in the tissues or of the blood within the vessels. The infiltration of both substances is associated with chromatolysis of the ganglion-cell. Symptoms of cerebellar disease may result in the lower animals from degeneration of the cell independently of any gross lesion.

4.—An unmarried woman, 52 years old, presenting hysterical symptoms, was discovered to be **addicted to the nightly use of 15 grains of sulfonal**. She promised to discontinue the practice, but several weeks later she developed symptoms of intoxication, with mental confusion, difficulty in speech, complete insomnia, with peculiar sighing dyspnea. The urine, withdrawn by catheter, exhibited a deep pink color. Stiffness of the legs developed, followed by paraplegia and loss of control of the sphincters. The reflexes were abolished, but sensibility was preserved. The paralysis rapidly spread upward and death resulted from heart-failure. Spectroscopic examination of both the urine and the blood disclosed the presence of hematorporphyrin. On histologic examination, degenerative changes were found in the liver, the kidney and the heart. The lungs were pigmented. The spleen was filled with greenish pigment, free and enclosed within cells; the fibrous trabeculae were greatly increased in size; the follicles were extremely well developed. The lymphatic glands were excessively pigmented. Histologic examination of the brain and spinal cord failed to disclose any noteworthy alteration.

5.—A man, 34 years old, had complained of stabbing pains in the legs for some time, the more marked on the left, with diffuse tenderness, especially pronounced over the nerve-trunks. The right lumbar region was the seat of continuous pain and tenderness with occasional attacks of sharp pain extending into the left lumbar region. Gait had been unsteady for 6 months. There was some stiffness of the joints and the left leg was thought to have become wasted. The knees were swollen and the feet edematous, especially the left foot. Prickling and tingling sensations also were present, but common sensibility was preserved. The knee-joints were absent. Micturition became frequent, and abdominal pain more severe. Death resulted from pulmonary edema. Upon postmortem examination a somewhat granular tumor, about 4 cm. long, 1 cm. in antero-posterior and 7 cm. in transverse measurement, was found lying upon the lumbar enlargement and the caudal nerves. In the lumbar region up to the first lumbar segment, the cord was much larger than usual in cross-section, but there was no evidence of infiltration of the cord by the new-growth. Sections of tumor stained with various dyes exhibited the appearances of a **melanotic sarcoma**.

6.—Careful examination of the blood was made in 16 cases of **leukemia**. Oligocythemia was found in all. As a rule the red cells appeared to contain less than the normal amount of coloring matter. Polychromatophilia occurred in nearly all of the cases. Vacuolation was sometimes observed in nucleated red cells, but this may have been factitious. Poikilocytosis was present in all cases. Nucleated red cells were present in all of the cases but one. The ameboid activity of the circulatory leukocytes appeared lessened. The polymorphonuclear cells were generally increased in the myelogenous or leukocyte cases, but not in those of lymphatic leukemia. The cells were quite variable in size in cases of leukocyte leukemia. They were frequently abnormal in shape. Changes in the neutrophilic granules were frequent. The nuclei presented much irregularity. The acidophilic polymorphonuclear cells were increased in the large majority of leukocytic cases. The conditions were different in the lymphatic case. The ungranulated mononuclear leukocytes were greatly increased in number in all of the cases of leukocytic leukemia. The acidophilic mononuclear cells were present in all of the cases of leukocytic leukemia. The lymphocytes were increased in a few cases, but were in general normal as to nucleus and protoplasm. The mast-cells were present in excess in most cases of leukocytic leukemia. Circulatory mast-cells were present in but one case of lymphatic leukemia. The myelocytes were present in all cases of leukocytic leukemia, but none was found in 4 cases of lymphatic leukemia, although a large number were present in a case of acute lymphatic leukemia. In but one instance was cellular division by mitosis

observed. Leukocytic degeneration may be protoplasmic or nuclear, or both. In a few cases the intercellular glycogen seemed increased, but in the majority it seemed normal. Charcot-Leyden crystals were not observed. The fibronic network was normal in all cases. The urine was carefully studied in 2 cases and the uric acid estimated in 3 others. The phosphates and the uric acid were increased. On chemical study of the blood in two cases the specific gravity was found reduced on account of the oligocythemia, but the reduction was partially nullified by the excess of leukocytes. The specific gravity of the plasma was above the normal in one case and normal in the other. The dried residue of the total blood was nearly normal in one case and somewhat below normal in the other. The dried residue of the plasma was above the normal in one case and normal in the other. The plasma-proteid, and of course its nitrogen, were above the normal in one case, but scarcely normal in the other. The volume of cells in one case was 33.4, in the other 41.6. The nonprotein nitrogen of the plasma was increased tenfold in one case and doubled in the second. The alkalinity was the maximum normal in the first case, slightly reduced in the second, and notably increased in a third. Assuming the excess of dried residue beyond the sum of the plasma-proteids, the erythrocytic proteids; the plaques and the ash to consist largely of the leukocytes, and the excess in nitrogen to have been derived largely from the leukocytes, the nitrogen-content in one case was nearly double the best obtainable figures and entirely normal in the other.

The following summary of the **biologic relations of the human leukocytes** is presented: The circulating blood contains six types of lymph-cells; the large lymphocyte and its direct descendant, the small lymphocyte derived from the lymph-glands and nodes; the ungranulated, large, mononuclear leukocyte, probably derived from the marrow; the polymorphonuclear neutrophilic leukocyte, derived from the myelocyte; the polymorphonuclear eosinophile, probably derived solely from the marrow; and the polymorphonuclear basophile, probably derived solely from the marrow. These cells have the power of reproduction by division, but this is not a prominent phenomenon; and these cells are, for practical purposes, not reproduced in the circulating blood. These types are distinct and not interchangeable, the distinctions being based upon differences in size, shape and reactions of the nuclei; the quantity and quality of their protoplasm and of their granulations; their differences in mobility; their different reactions in the envelopment of foreign bodies; their varying relations to the functions of phagocytosis and bactericidal action; their different relations to clotting; and their widely distinct reactions to various disease processes, particularly to infections, blood-diseases, and experimental procedures. There is a differentiation in the leukocytic reaction to disease-processes in different parts of the body—the blood, the colonic tissues, the alimentary tract, and the skin. Lymph-tissues are derived only from lymph-tissues and produce no other tissue, either physiologic or pathologic.

The following varieties of leukocytosis are described: (1) General in type; (2) polymorphonuclear; (3) lymphocytosis; (4) mononuclear; (5) eosinophilic; (6) basophilic; (7) myelocytosis.

The alterations in the tissues in 2 cases of acute leukemia and in 10 cases of chronic leukocytic leukemia are described.

For the purpose of determining whether persistent leukocytosis is capable of inducing any of the circulatory or local cellular changes of leukemia, the spleen was removed from 3 dogs. Only temporary moderate lymphocytosis developed, and the lymphatic glands were not enlarged.

Leukemia is considered a peculiar variety of leukocytosis rather than a neoplastic condition. Its specific cause is not known. Two types and a mixed form occur, namely, lymphocytic leukemia, myelogenous or leukocytic leukemia and myelolymphocytic leukemia.

It was found that in cases of leukemia the use of arsenic tends to diminish the number of leukocytes, and to augment the number of red cells, although improvement in the objective symptoms does not always coincide with the beneficial effects upon the blood. In other cases, however, the drug has no action upon the blood or the symptoms.

7.—This paper discusses the **anomalies** that may be observed in the **red blood-corpuscles**, together with the de-

generations that can be induced by means of water, weak acids, saline solutions, poisons, pressure, heat, cold and blood-serum. The viscosity of the red cells, the occurrence of vacuolation, the presence of granular masses or streaks, the process of budding and fragmentation, total necrosis, irregular fragmentation, ameboid movements and polychromatophilia are also considered. Attention is devoted further to alterations in size, irregularity in shape, vacuolation, abnormal viscosity, shadow corpuscles, polychromatophilia and alterations in resistance. Some experiments in isotonicity are recorded, and the effects of cold, of hypotonic saline solutions, of saline solutions in the living body, of heat, of serum from cases of chlorosis, leukemia, pernicious anemia, disease of the heart, and of heterogenous corpuscles in the circulation are described. It was found that the first stage of degeneration is always a beginning resolution of the vital or chemic combination of the hemoglobin and the stroma, as exhibited in slight areas of decolorization or, in an earlier or more diffuse form, in slight irregularity of contour. Next the hemoglobin is completely altered and removed, leaving areas of decolorization, in which the hemoglobin may be seen as granular streaks and particles. Occasionally the hemoglobin separates without distinct decolorization of the corpuscles. Complete decolorization with the formation of shadow corpuscles is the last stage of this simple form of degeneration. Irregular contractions of the protoplasm may or may not attend this form, but it may occur independently; then, however, as a result of gross insults, such as by heat. Budding and marked poikilocytes are the results. A more general change may lead to poikilocytes by slow ameboid movements. Microcytes may be split off in either case; while macrocytes are found in some instances, probably as a result of inhibition of liquid. Complete or partial fragmentation may result from slight pressure or other mechanic causes in a corpuscle somewhat degenerated, though the same causes would leave a normal erythrocyte unaffected. Changes of color-reaction, chromatophilia, may or may not be seen in degenerated red corpuscles. All of the changes described may occur in the corpuscles of anemic diseases and indicate some causative influence from without, probably the serum. The discovery of changes in the red corpuscles in cases of anemia is therefore indicative of but one of the pathologic conditions and perhaps not the first. The underlying disorder is not improbably often chemic and connected with disturbances of metabolism or organic action. The altered serum changes the corpuscles. The presence of altered red cells is not always an indication of improper formation, but in many cases the alterations are the result of degeneration.

8.—As the result of an experimental investigation it was found that following severe hemorrhage in the dog the replacement by saline solution of the volume of blood lost is followed by a most rapid restitution of the sugar and the proteids of the plasma, probably derived from the tissues by direct lavage.

9.—An imperfectly nourished man, 38 years old, with a previous history of lead-poisoning, but without evidence of disease of the kidneys or of the circulatory organs, was subjected to **metabolism experiments** for a period of 10 days, throughout which water was given in large amounts. The results obtained were contrasted with those of a previous period of slight water-ingestion, the amount of nitrogen ingested and excreted being accurately determined. When water was given in large amounts the degree of nitrogen-retention was much diminished and metabolism was increased. It could not be determined that the use of large amounts of water had any distinct effect upon absorption.

10.—As the result of an experimental investigation upon rabbits it was found that of all the etiologic factors that enter into the **pathogenesis of appendicitis**, imperfect drainage of the organ plays the most conspicuous part. Whenever this is present and persists for even a brief period of time, there are bound to arise definite, and at times serious, consequences. As a direct result of the interference with drainage the innocuous *Bacillus coli communis* is converted into a virulent organism. It is this exalted virulence, as well as the inability of the organ by peristaltic action to rid itself of the organism themselves or of their toxins, that is directly responsible for the local lesions and the constitutional disturbance. The varying degrees of virulence, as attained by microorganisms under certain predisposing conditions—most

conspicuously that of imperfect drainage—suggest an explanation for the wide range of severity manifested in individual attacks. Next in importance to the parts played by insufficient drainage and microorganismal activity is the question of circulatory disturbances. The result of this is twofold: The tissues lose thereby in resistant power, and the virulence of the bacteria is increased. The insignificance attached to the presence of foreign bodies in the human appendix has been well borne out by experimental work.

11.—The patient was an unmarried white woman, 60 years old, deaf and lacking in intelligence, who appeared to be suffering from weakness and senility. The area of cardiac dulness extended one inch to the right of the sternum, and a systolic murmur was heard at the apex of the heart. Postmortem examination disclosed, in addition to **chronic obliterating phlebitis of the left superior pulmonary vein**, effusion into the left pleural cavity, moderate ascites, atelectasis of the superior lobe of the left lung, chronic fibrous myocarditis, chronic sclerotic endocarditis with mitral insufficiency, cirrhosis of the liver, chronic interstitial nephritis, general atheroma, and a calcareous fibroma of the uterus.

12.—See this JOURNAL, Vol. I, No. 21, p. 956.

13.—In cover-glass preparations of the sputum from 8 of 9 cases of **whooping-cough**, and from the trachea at autopsy in one case an organism believed to be the Czaplewski-Hensel bacillus was found in predominating numbers. The corresponding organism was found in cultures from the sputum in 7 cases. In several instances favorable results were obtained from the injection of blood-serum from individuals who had previously passed through attacks of whooping-cough.

Influenza with Four Distinct Pneumonic Attacks Accompanied by Otitis Media Purulenta, Cerebral Hyperemia, Colitis, Marasmus; Recovery.—At the meeting of the American Medical Association held at Atlantic City, June 5, 6, 7, 8, 1900, Ullman reported the case of a child, aged 20 months, in whom influenza was complicated by 4 distinct attacks of pneumonia, each of which ended by crisis. Acute purulent middle-ear disease accompanied by a purulent discharge from the left eye and nostril and cerebral hyperemia that produced attacks resembling meningitis in character also developed. As a result of colitis the patient was unable to assimilate the simplest food and consequently marasmus resulted. No bacteriologic examination was made because the child did not expectorate. Blood-examination showed secondary anemia and a leukocytosis of which 97% were lymphocytes and 3% polymorphonuclear leukocytes; there were also macrocytes, microcytes, and poikilocytes. The patient recovered. [J.M.S.]

Plantar Reflex and its Associated Phenomena, Particularly Babinsky's Phenomenon.—Waller and Paul (*Journal of Mental and Nervous Diseases*, June, 1900) contribute a valuable article. The latter they regard as characterized by a pronounced extension of the great toe with or without extension and separation of the other toes. In regard to the plantar reflex, studies upon young women apparently prove that it is not influenced by fatigue. It was present in 40 of 55 normal cases. In 5 cases it was absent and in 10 differed in the two feet. Similar studies of a great variety of patients gave about the same results. Some 200 cases of disease of the nervous system without lesion in the pyramidal tract were examined. In 65% the reflex was normal; in 2% Babinsky's phenomenon was absent, but in these, implication of the pyramidal tract could not be excluded. In infants, the reflex movements of the toes could not be definitely determined, but dorsiflexion of the foot seemed to be clearly constant. The authors then give their results in cases in which the pyramidal tract was distinctly involved. Babinsky's phenomenon was present in 7 of 9 hemiplegias, in 15 of 24 diaphragmias, and in all of another group of hemiplegias, and in 2 cases of spinal disease. About 200 cases were examined in which the pyramidal tract was diseased, and in 70% the Babinsky reflex was present. In a few cases, it was present when pyramidal disease apparently could be excluded. It was very much more constant than exaggeration of the patellar jerk or the Achilles tendon reflex, and apparently is the earliest symptom to appear in the pyramidal tract disease. [J.S.]

1.—Stokes reports a number of cases which he believes somewhat refute the idea that the wounds made by **Mauser bullets** are "humane and harmless." His experience in the Boer war, acquired in the Maritzburg military hospital and in the General Hospital, Maori River, led him to believe that the character of the gunshot wounds in the early part of the campaign differs materially from those observed later, both as regards the gravity of the wound and the increased difficulty of keeping them aseptic. He believes that the Boers frequently used expanding bullets, and that another cause for the increased severity of wounds is that later in the war the range became much closer. He reports 8 cases in which amputation was necessary on account of the severity of the injury causing either splintering of the bone or extensive laceration of the soft parts. [G.B.W.]

2.—**Antenatal diagnosis** includes the discovery of normal pregnancy and of plural pregnancy, of fetal death, of diseases and monstrosities of the fetus, of hydramnios, and of morbid conditions of the placenta. All these matters must be kept in mind in examining a patient who may be pregnant, and in all of them there is at any rate an increasing probability that the diagnosis may be thoroughly well established under favorable circumstances and with care and skill. The making of the diagnosis of the antenatal morbid state during antenatal life will be best accomplished by taking up the following lines of investigation in order. First, the previous medical history of the woman, both general and sexual, must be inquired into; for there are certain circumstances which may be regarded as commonly preceding the development of morbid states in pregnancy; secondly, the past history and present state of the father, and the family history on both sides ought to be taken into account; for there are fetal diseases and embryonic deformities which appear to be hereditarily transmitted; thirdly the maternal symptomatology during the pregnancy which is in progress must be carefully investigated; fourthly, a very complete physical examination ought to be made of the maternal organs, and especially of the abdominal viscera; fifthly, the fetus should be fully examined by the hands, by the ear, by the cephalometer, by the Röntgen-rays, and by any other means of exact research that may yet be invented; and finally, the maternal urine and blood should be subjected to a chemical and microscopical investigation, as it is beginning to be realized that the condition of the fetus *in utero* is to some extent reflected in the composition and character of the maternal excretions. Ballantyne considers the mother's previous reproductive history is of much more immediate value in the diagnosis of antenatal morbid states than is her purely medical record. Therefore the menstrual habit and type ought to be ascertained and any abnormal conditions noted. The condition of the mother as to marriage must be inquired into, whether she married early or late in life and whether she married a near relative, as uncle or first cousin. The history of the previous pregnancies of the pa-

tient may yield information of the very greatest value in the making of a diagnosis. [W.K.]

3.—Barr does not believe in the cold-bath treatment of high temperatures in **pneumonia** because it involves the free administration of alcohol of which he does not approve and because it chills the extremities. He believes that a large moist poultice, if the patient is lightly clothed and evaporation is allowed to take place freely, removes a great amount of latent heat; the object is to cool the patient, not to keep the poultice warm. He also advocates the use of one or more large abdominal ice-bags to lower the temperature, to raise the general arterial pressure by the action of the cold on the splanchnic area, and to diminish the frequency and increase the depth of the respirations. This method must be adopted early in the disease or not at all. If the lung is in the stage of gray hepatization the use of the poultice will produce better cooling effects. Ice should not be used for very old or very fat people. Bleeding should never be adopted after the first 45 hours and never at any time if the pulse is small, feeble, and compressible. He advises the use of 10 minim doses of wine of antimony every 4 hours to an adult, never to be continued beyond the third day. Opium should be used to induce sleep; 2 or 3 10 grain doses of Dover's powder during the night often answer. In alcoholic subjects the combination of opium and antimony answer well. Where the lung is engorged and the right side of the heart is handicapped chloral is preferable to opium. The sick room in this disease should be well lighted, well ventilated, and the temperature should be about 65° F. Nausea and vomiting may be treated by washing with warm water or by a calomel purge. When the pulse is feeble and expectoration is difficult a mixture of ammonium carbonate, potassium citrate, or potassium nitrate, and citrated caffeine is advantageous. Cardiac failure may be met by strychnin, caffeine, and digitalis. Terebene is the best remedy in the late stages with profuse expectoration. During convalescence tonics are required. When the pulse is small and irregular and the vessels are rigid a small amount of alcohol may do good. In alcoholic cases with delirium, alcohol, atropin, and morphin are valuable; if necessary chloroform may be administered by inhalation for its quieting effect. The food should be liquid, light and nutritious. [J.M.S.]

5.—Gastroenteritis, enteric fever, and dysentery were common in the Imperial Yeomanry Base Hospital. Washbourn considers the alimentary canal the portal of entry for the microorganisms in each disease. As etiologic factors he places flies, dust, and water in the order mentioned. He thinks that the drinking of Modder River water and the use of fresh meat received from Capetown were responsible for many cases of **gastroenteritis**. In the treatment of **dysentery**, which was not very fatal, 2 cases out of 158, the author used ipecacuanha in 30 grain doses after abstinence from food and a dose of laudanum or chlorodyn. The dose was repeated in 4 hours. Magnesium sulfate was given in dram-doses every hour until the motions became fecal. He thinks that inoculation does not have a marked effect in mitigating the attacks of **enteric fever**; 2 patients who died of the disease had been inoculated. Several patients presented enteric fever after an attack of dysentery. There were cases in which the only diagnosis possible was simple continued fever. No case of **malaria** arising in South Africa has been seen. [J.M.S.]

6.—Low made sections of the **filariated mosquitos** of the **genus culex** after colloidin embedding. It was found that the young filaria, after reaching their highest stage of development in the insect, instead of lying passively in the thoracic muscles, leave that tissue and, in the vast majority of instances, travel forward in the direction of the head of the mosquito and pass into the loose cellular tissue which abounds in the prothorax in the neighborhood of the salivary glands. After a short sojourn in the prothorax the worms enter the lower part of the head and coil themselves up in the loose connective tissue immediately below the cephalic ganglion and the salivary duct. From the head they may be traced passing into the proboscis, making an independent passage through the base of the labium, and pushing forward along the proboscis between the labium and hypopharynx, among the stylets. These parasites then enter the human tissues when the mosquito next feeds on man. This statement could only be proved by a dangerous

experiment; but the evidence is strongly in favor of the hypothesis. [J.M.S.]

7.—Baker reports the case of a boy, aged 13, who was suffering from **pneumonia**. The patient was sleepless and delirious and the temperature rose to 104.4° F. Five grains of Dover's powder every 4 hours, later reduced to 2½ grains at like intervals, produced the most decidedly good results. The disease was complicated by severe earache due to the impaction of a plug of cotton. [J.M.S.]

8.—Rees advises the following method for the **preservation of mosquitos**. After killing the insect and separating the legs, place a large drop of thick xylol Canada balsam on a slide and invert it on the mosquito, which should be resting on its back. Then arrange the wings and legs again if necessary; pour on some thin balsam, which will straighten the proboscis and antennae. After hardening the excess of balsam is chipped off, a glass ring is put on the slide around the balsam, and the chamber is filled with balsam so that the upper surface is convex in order that when the cover-glass is applied no air-bubbles shall remain. [J.M.S.]

9.—Whiteford calls attention to the necessity in cases of **strangulated hernia** of emptying the bowel above the constriction, thus relieving not only the constipation, but relieving the patient of the accumulation of feces from which he has been absorbing various poisons. [G.B.W.]

10.—Raw reports a case of **cesarean section and embryotomy** on the same patient, whose greatest conjugate diameter was 2½ inches. She was short but well developed and very rickety, with spinal angular curvature. Surgical emphysema also complicated the condition. [W.K.]

1.—Anderson gives case-histories of patients who have been benefited by **tuberculin treatment** and of those in whom the use of **tuberculin** has served to **clear the diagnosis**, otherwise obscure. He believes that if used with reasonable care the tuberculin is both efficient and safe in the human subject. Cases of external tuberculosis are the best for studying the effects of the treatment by this substance. Thirty-five patients suffering from lupus vulgaris, 7 from scrofuloderma; and 3 from lupus erythematoses were treated, all except one with the old tuberculin. The excepted patient received tuberculin (T. R.). The only other treatment was 2 to 3 ounces of cod-liver oil daily and generous diet. Statistics concerning the result or the treatment are given. The author is of opinion that the local inflammatory action of the remedy effects the improvement. The treatment must always be accompanied by hygienic measures. He thinks tuberculin (T. R.) is the safer of the two forms of tuberculin.

He gives tables for diluting the tuberculin for administration. [J.N.S.]

2.—In the alimentary form of **diabetes** the erroneous state observed in connection with the urine consists in the abnormal presence of dextrose. As a result, when the urine is examined quantitatively by cupric oxid reduction and the polarimeter, the figures given by the 2 methods are in accord. In contrast to this **simple form of diabetes** there is a class of the affection in which the dextrose in the urine is derived from a two-fold source. It is present as the result of a faulty carbohydrate assimilation and as the result of an abnormal proteid disintegration. This is also attended by other abnormal degenerative products, and it is these substances that produce the diabetic coma. Pavy proposes the term **composite diabetes** for this latter variety of the complaint in contradistinction to the simple alimentary form. In the composite form the chain of associated products of faulty proteid disintegration includes B oxybutyric acid, diacetic acid, and acetone. The amount of these products may serve as an indication of the degree of abnormal disintegration taking place within the economy. The existence of ammonia in combination with sulphuric or phosphoric acid in the urine of a diabetic patient is also evidence of abnormal proteid destruction. The article is continued. [J.M.S.]

3.—From a study of the **uric-acid salts**, Tunncliffe and Rosenheim conclude: 1. That there is no evidence of the existence of quadriurates either in the artificial or the natural amorphous urinary deposits or in the fluids of the body. Under these circumstances it is advisable to discontinue the use of the term quadriurate. 2. That the substances obtained artificially under the conditions supposed to produce quadriurates consist of mixtures in varying proportions of uric acid and biurates or of pure uric acid or pure biurates alone. 3. That the natural amorphous urinary deposits consist of a mixture of uric acid with urates of sodium, ammonium, potassium, calcium and magnesium, (containing, in the majority of cases, phosphoric acid in addition). 4. That the property of some natural and artificial amorphous urates of showing the formation of uric-acid crystals under the influence of water is due to the dissolving out of the more soluble biurate moiety and a change in physical state of the remaining uric acid. 5. That any theory concerning the pathology or treatment of gout or the uric-acid diathesis built upon the assumption of the existence of quadriurates requires reconsideration. 6. That the existence of two forms of uric acid (the tautomonic lactane and the lactine form) may explain the variation in the physical and physiologic behavior of this acid and its salts. [J.M.S.]

4.—In considering the **management of the anesthetic in cases in which respiratory impediment exists**, Buxton first defines primary circulatory failure as a depression of the circulation which is preceded by no interference with respiration; and secondary circulatory failure as a circulatory depression consequent upon and causally related to interference with the functions of respiration. The pulmonary circulation is materially assisted or hindered according (1) as the thoracic movements are maintained and are competent, and (2) as the gaseous composition of the blood is maintained at its physiologic standard. Obstructed breathing, due to blocking in the upper air-passages, commonly arises from enlarged tonsils, pharyngeal abscess, enlarged tongue, or old adhesions between the posterior wall of the pharynx and the tissues of the faucial arches. Goiter, angina of Ludovic, lymphadenoma, lymphadenitis render anesthesia difficult and dangerous. Patients with emphysema, and very fat persons also, offer mechanic obstacles to the respiratory function. The position of the patient for operations in the dorsal region offers a serious obstacle to surgical anesthesia. Operations on the thorax also present many difficulties to the anesthetist. [J.M.S.]

5.—Cowan reports the case of a man, aged 30 years, suffering from mania with incoherence who presented an **old dorsal dislocation of both hip-joints**. In spite of the fact that the friends of the patient asserted that the condition was due to a severe thrashing received at the hands of a drunken man when the patient was 7 years of age, and that the patient did not limp or present deformity before that time, the author believes the condition to be **congenital**. Progression was accompanied by a marked rolling, waddling gait. [J.M.S.]

6.—Probably the most generally accepted view is that **puerperal eclampsia** is due to a toxemia of a urinary nature, toxic substances being retained in the blood which should have been excreted by the kidneys, and the frequent association of albuminuria with eclampsia certainly supports this theory. It has been stated that one pregnant woman in 40 is albuminuric, and that of these one out of every 4 develops eclampsia; that eclampsia without albuminuria is of rare occurrence—one case in 10. From these facts the practical conclusion is drawn that albuminuria should always be looked for in pregnant women, and actively treated during pregnancy when detected. As regards treatment, there can be no doubt that the chief indication is to eliminate the toxic matter from the circulation, or, failing this, to dilute it as much as possible. With this object in view purgatives, diuretics, and diaphoretics are given, and Dr. R. Jardine has recently strongly advocated the use of saline injections. Spurr reports 3 cases of puerperal eclampsia, in 2 of which he relied on calomel and croton oil respectively as purgatives, in each instance with very satisfactory results; but in any future case he would feel more inclined to resort to the more rapid and certain method of emptying the lower bowel with copious and repeated enemas. The second indication must be to counteract or modify the effects of the poison in the system and for this purpose numerous drugs have been recommended—morphia, chloral hydrate, bromids, chloroform, veratrum viride, etc. After the experience gained in the 3 cases reported, Spurr would never hesitate to place entire reliance on the mixture of chloral hydrate and bromid, supplemented if need be by the prolonged administration of chloroform; but in a disease of such gravity, arising from a toxin, whatever its nature, of such virulence, it is absolutely necessary to give these counteracting drugs in full doses, and above all to persevere in the line of treatment adopted and that even in cases apparently hopeless. [W.K.]

7.—A man of 20 was operated upon for **compound fracture of the skull**. The symptoms of depression which had previously existed were relieved and his condition gradually improved for several days; then a rise of temperature and mental dulness developed, and death followed 28 days after the injury. Necropsy revealed a **brain-abscess** at the site of the injury. In a second case, a man of 56 entered the hospital with right hemiplegia. His condition was such that no definite history could be obtained; convulsions developed, and the man died on the twenty-fourth day after the injury. The necropsy showed the brain tissue to be much softened, and three large clots were found—one high up just inside the central fissure, a second lower down inside the middle frontal convolution, and a smaller clot in the occipital region. In the third case, a boy received an injury of the head so severe that it was possible to insert a probe by its own weight 2½ inches into the brain. The hemorrhage was arrested and an antiseptic pad was applied; without further intervention recovery followed in 3 weeks. [M.B.T.]

8.—A man of 28 had suffered from **constipation** for 4 years, relieving himself only by enemas and purges. Celiotomy was performed and the sigmoid flexure was found dilated to the size of a stomach and filled with fecal matter; this portion of the intestine was cyst-like in structure; it was emptied and sutured to the abdominal wall, and since this time the patient's bowels act normally. In a second case, a man of 42 had suffered from constipation for 8 or 10 years; his condition had been worse for the previous year and symptoms of acute intestinal obstruction had occasionally developed. Treatment by purgatives was ineffectual. On opening the abdomen the **sigmoid flexure** was found **enormously dilated**, extending into the pelvis; it was opened and sutured to the abdominal wall; uninterrupted recovery followed. The bowel movements have since then been normal and the patient has gained much in weight. [M.B.T.]

9.—In the treatment of **fractures of the lower jaw** Carter advises wiring; he prefers to use the dental engine in drilling the holes and then inserts an annealed silver-plated copper wire which is stronger and more ductile than silver, the wound should be well irrigated and the parts dusted with iodoform and boric acid; for some time no conversation should be allowed and mastication is forbidden for several weeks. [M.B.T.]

10.—Elliott reports the case of a woman, aged 44 years,

who presented no family nor personal tuberculous history. The patient's husband had died of pulmonary tuberculosis 3 years before her own illness and the patient had slept with him nearly to the end of his life. Suddenly, in 1894, the patient experienced a sharp pain in the right breast which soon became worse, and was accompanied by dyspnea and cough. Soon a pleural effusion was discovered which was followed by the development of hectic symptoms. Before aspiration was done the patient had a violent fit of coughing and expectorated about 3 pints of greenish-yellow pus, which toward the end of the paroxysm was mixed with blood. The next examination of the chest showed the presence of air and fluid. Seven weeks after the commencement of the illness the symptoms had disappeared, and in 3 months the patient was able to take up her duties as a monthly nurse. The patient was perfectly well 2½ years later with only a slight pleural friction on deep inspiration as the remains of the **pyopneumothorax**. [J.M.S.]

11.—A boy of 10 years had severe pain in the sacral region which made it impossible for him to sleep or assume the sitting posture. On rectal examination it was found that the 2 lower segments of the sacrum were tilted inward and that the continuity of the sacral curve was lost. The coccyx was removed and since then the boy is free from pain and able to sit comfortably. [M.B.T.]

12.—Newman reports the case of a woman, aged 30 years, who was suffering from **acute rheumatism**. On the twenty-first day of the disease the temperature rose to 107.8° and the pulse was 174, weak and irregular. The **hyperthermia** continued for about 24 hours. Sponging with water at 45° F. reduced the temperature in that time, and thermometer subsequently did not register above 102°. A soft mitral systolic murmur was heard near the end of the attack. [J.M.S.]

13.—A girl of 19 had suffered from anemia and amenorrhea for 2 years; pills of the dried sulfate of iron were administered with some improvement. This was temporary, however, and later a large amount of fluid developed in the abdomen; the latter increased in size until the patient suffered decided discomfort and became very feeble. An incision was made and about 8 pints of blood-stained fluid were drawn off and a drainage tube was inserted; the fluid reaccumulated and the patient's condition became very unsatisfactory. An attempt was made to establish collateral circulation by suturing a piece of omentum about 2 inches square to the abdominal wall. The superficial abdominal veins soon began to enlarge and the patient improved in health and strength and is now reported to be in excellent condition. The trouble is believed to have been due to **lymphatic leukemia**. [M.B.T.]

14.—A woman of 61 was admitted to the hospital with symptoms of a strangulated left **femoral hernia** of 6 days' duration. Herniotomy was immediately performed, the sac was gangrenous and infiltrated with pus; it contained a loop of intestine which had become twisted, forming a small **volvulus**, the neck of which lay just within the abdominal cavity close up against the femoral ring. The gangrenous loop was removed and anastomosis was performed with the aid of a Robson's bobbin; death followed 26 hours after the operation. [M.B.T.]

1.—Sheffield is of opinion that the digestive system is

affected in **influenza** by the patient's swallowing saliva which contains the bacillus of Pfeiffer. He agrees with the generally accepted idea that the germs gain entrance into the system primarily through the respiratory tract. The influence of this disease upon the respiratory, digestive, and nervous systems is discussed. Both croupous and bronchopneumonia, meningitis, otitis, mastoiditis and nephritis are complications or sequels. Sheffield is of opinion that the same prophylaxis should be employed to prevent the spread of influenza as is for measles, scarlatina, etc. Isolated cases are not easy to diagnosticate, but the following will aid in the diagnosis: (1) The invariable presence of the bacillus of Pfeiffer in the expectoration; (2), the simultaneous development of respiratory, digestive, and, at times, nervous phenomena; (3), early and pronounced prostration, incommensurate with the severity and duration of the attack. **Sodium benzoate** is the very best drug in this disease, as it meets all the requirements. [J.M.S.]

2.—Bodenhamer opposes the view taken by Martin that there are **valves in the rectum**. He says the corrugated condition of the mucous membrane of the rectum is caused solely by the tonic contraction of the involuntary muscular fibers. Plicae of similar kind are caused by the tonic contraction of the sphincter ani externus. All the corrugations and plicae may be temporarily obliterated by mechanically distending the rectum. This could not be done if they were true valves. They are composed solely of mucous membrane. Their function, like that of the curves of the rectum, is to prevent a too rapid descent of the contents of the bowel, not as valves, but as a brake. The arrangement of these plicae and corrugations is never constant, and the latter do not oppose each other so as to completely close the lumen, as a valve would do. Within the margin of the anus are a number of sacculi, or lacunae, but they are in no sense valves. No valves are needed by the rectum, as the sphincter muscles are sufficient for all its needs. [J.M.S.]

3.—Killebrew believes that greater regard should be paid to **asepsis in obstetrical cases**. However, even with the strictest precautions some cases will become infected. He regards puerperal infection as a surgical disease and believes it should be treated surgically. If the infecting bacteria have penetrated deeper the walls of the uterus or invaded the peritoneal structures, curettage and opening of Douglas's cul-de-sac, with the proper application of antiseptic dressings must be resorted to. If the case is seen early, treatment should be begun by giving intrauterine irrigations or normal salt solution or saturated solution of boric acid. [W.K.]

4.—Crawford believes that **formalin** has not received that consideration at the hands of surgeons and obstetricians which it merits. He says it comes nearer meeting all the requirements for a perfect disinfectant than any other substance yet employed. It ranks with the best germicides. It is both an antiseptic and a deodorant. It is less irritating to both hands and wound than any other efficient drug. It does not injure instruments, and is practically innocuous; even the peritoneal cavity may be irrigated with it, and a considerable amount may be left in that cavity to be absorbed. Formalin is to be differentiated from formaldehyd, as the latter is 2½ times as strong as the former. For washing the hand and surface of the body a ½% solution of formalin is used for cavities, a ¼% or ⅓% is sufficiently strong. For gynecologic work it is almost an ideal disinfectant, also in operation for appendicitis, particularly when there is pus and irrigation is necessary. It is particularly useful for packing and draining pus-cavities, being far superior to iodoform. It meets all the requirements in obstetric practice. Another advantage is its cheapness. One dram of formalin added to 3 pints of water makes a ¼% solution. [J.M.S.]

5.—In a case of **cleft palate** in which the Langenbeck and Davis-Colley operation had failed to close the immense defect, Beck utilized a lateral flap from near the base of the tongue which was united with the freshened edge of the palate. The gaping wound margins of the side of the tongue were accurately united, the floor of the mouth was packed with iodoform gauze and a mild solution of boric acid was sprayed through the nostrils every 15 minutes for 9 days; the base of the flap was divided, and one week later the flap was united with the opposite margin of the cleft. This operation was suggested by the ease with which extensive resection of the tongue is tolerated by carcinomatous patients. [M.B.T.]

6.—Lockard quotes Rokitansky's theory that the **laryngeal phenomena in typhoid fever** are manifestations of the general disease, a true metastasis of the poison to parts of the laryngeal structure. This the writer considers true in the main. Typhoid is not a disease of the intestines alone, but of the entire lymphatic system. The lesions in the larynx are separated into those due to the toxins, specific lesions, and those due to malnutrition. The specific lesions begin by swelling of the more prominent adenoid masses found in the sinus pyriformis and at the base of the arytenoids. It appears that their further progress is similar to the typhoid ulcers of the intestine. The laryngeal ulcers are usually from 2 to 6 in number, round or oval, sharply circumscribed, and generally appear at the end of the second week. The presence of these ulcers makes the prognosis much graver. Purulent perichondritis may develop. A case is reported by the author where a man of 35 had a laryngeal ulcer during an attack of typhoid. Dyspnea was so great that tracheotomy had to be performed. Pus was evacuated and recovery followed. Landgraf maintains that the larynx is involved in 11% of all fatal cases. [J.M.S.]

7.—McKinney, while unwilling to accept the arbitrary dictum of Bosworth, that **atrophic rhinitis** is a sequence to chronic purulent rhinitis of childhood, leans strongly to the main proposition of Bosworth's belief. He cites several cases whose history inclines him to this view. [J.M.S.]

Medical Record.

June 30, 1900. [Vol. 57, No. 26.]

1. Concerning the Peritoneum and the Treatment of Exudative Peritonitis. ALBERT A. BERG.

1.—Berg considers: 1. That the introduction of **pyogenic bacteria into the normal peritoneal cavity** produces no evil results, provided they are not mixed with caustic or irritating substances. 2. The introduction of nonpyogenic organisms into the normal peritoneal cavity produces different results, depending on whether the organisms injected cause decomposition of albumin. In the latter case even considerable amounts of bacteria and fluid are absorbed, without evil consequences, while in the former general sepsis, but not purulent peritonitis, results. He discusses at length the methods by which the peritoneum absorbs substances from the peritoneal cavity and concludes that: "In order that bacteria should develop on the peritoneum and produce a bacterial peritonitis, there must be already a mechanical or chemical peritonitis. A primary bacteria peritonitis is not a possibility, because the normal serosa, by its resorptive property, absorbs the implanted bacteria, or else it does not respond by inflammation to those bacteria." He believes so long as peritoneum is peritoneum, so to speak, drainage is superfluous and objectionable. When, however, a region has been denuded of its peritoneal covering, this area must be drained, for these parts no longer possess their rapid absorbing power. Berg protests against the too active handling of this most delicate tissue. The pendulum of our activity is gradually swinging the other way, and we are commencing to recognize that gauze packing, irrigation, evisceration, not only injure the delicate nervous mechanism of the peritoneum, but also favor, by interfering with the activity of the cellular process, the local sedimentation of bacteria with their consequent local development and deleterious effects. The peritoneum has been endowed with its own protective attribute, which is not heightened by manipulation or the introduction of foreign material. If we supplement the internist's treatment of peritonitis, by a removal of the cause of the inflammation and cease to abuse and injure this delicate membrane we will meet with most gratifying results. [W.K.]

2.—English's treatment for **typhoid fever** is first to give quinin to exclude malaria, then to give calomel. Afterward he keeps the bowel as empty as possible. For this pur-

pose he gives aloin and podophyllin, and for the purpose of keeping the bowel as nearly aseptic as possible he gives carbolic acid camphor in doses of 10 to 12 drops every 2 hours for 48 hours, then decreasing the dose. He gives large amounts of water as a diuretic and diaphoretic. He watches carefully for tympanites, and so far as possible prevents it by the measures previously described, and if heart-failure occurs he gives digitalis and whisky. The food which he relies upon is dissolved beef during the first 2 weeks; after this he adds some milk, and he especially recommends "eggemon," which consists of an egg beaten up with the juice of one lemon and a little sugar. [D.L.E.]

3.—Two cases of **akromegaly** are reported in which pituitary tablets were given for several months with no improvement in the symptoms. In one case there had been bitemporal hemianopia resulting from the pressure of an enlarged prehypophysis upon the optic chiasm. The vision was progressively lost, indicating that the hypophysis had continued to enlarge. Leszynsky thinks that it is practically established that akromegaly is not due to obliteration of the glandular structure of the hypophysis. He considers that there are no rational grounds for the administration of pituitary extract in akromegaly. [D.L.E.]

4.—Elsberg recommends the following method of repeated **sterilizing of sponges** by boiling: The sponges are freed from calcareous matter by immersion for 24 hours in 8% muriatic acid solution, and are then thoroughly washed in water. They are then boiled 15 minutes or longer in the following solution: Potassium hydrate, 1 part; tannic acid, 3 parts; water, 100 parts. They are washed in water, carbolic acid, or sublimate solution until all of the potassium hydrate tannic acid mixture (which is of a dark brown color) is removed. The sponges are preserved in 5% carbolic-acid solution. Sponges that have been used can be resterilized by washing them in water, and then boiling them once more in the solution, etc. The solution can be used any number of times, as it does not deteriorate by boiling or by age. Sponges prepared in this manner are absolutely sterile, and they will be found to have retained all their physical qualities—size, softness, elasticity, power of absorption, etc. [M.B.T.]

1. The Prevention of Dystocia Due to Fetal and Pelvic Disproportion. EDWARD A. AYERS.
2. The Treatment of Tumors Complicating Pregnancy. BROOKS H. WELLS.
3. The Indications for Premature Delivery, with Special Reference to Eclampsia and the Preeclamptic State. S. MARX.
4. When Is It Proper to Interfere in Apparently Difficult or Delayed Cases of Labor, Especially in Primiparas. MALCOLM MCLEAN.

1.—Ayers is profoundly impressed with the importance of the subject of **dystocia due to fetal and pelvic disproportion**, and believes that more careful consideration should be given this subject. It should be considered briefly in two divisions; first, to what extent can we foresee the outcome of fetal passage through the maternal pelvis? secondly, to what extent can we, by means of such foresight, prevent the evils that threaten? In multiparas, we have as aids to prognosis the previous history of labors, and in both classes paternal characteristics, pelvimetry, fetal palpation, cephalometry and tentative engagement of the fetal head. He thinks that in studying the physical characters of the parents the bones are the most important point to be considered in forming a prognosis of fetal size at birth. The heaviest children are usually born of parents of large bone. If with large-boned parents there is a mutual family history of high intellectual development, we may expect large head-diameters in children at birth. When the parents are of opposite types, he believes the **mother's character will predominate**. Excess of fat in the mother increases the amount of soft tissue in the pelvic canal, but more materially causes dystocia, in that the dynamic force in expulsion is weak. Anemia, chlorosis, or other weakening conditions may cause loss of *vis a tergo*. Pelvimetry, abdominal palpation and cephalometry should

be the methods used in determining the relations between the fetal and maternal parts, and any practical results from the above carefully-applied efforts to make early diagnosis of dystocia must obtain in either the restrictions of fetal growth, the induction of labor, or preparedness for obstructions in labor. The diet recommended by Rowbotham, of confining the patient largely to vegetable acids, with the intention of preventing the formation of earthy salts, is valuable. If induction of labor is decided upon, the best methods are: (1) The sterile, solid, flexible bougie; (2) the small Barnes bag, used very slowly to excitation of pains only; and (3) the tampon—any of these to be preceded by the administration of a full dose of castor-oil. [W.K.]

2.—Considering the dangers incident to the **complication of pregnancy** by various new growths involving the uterus and pelvis, Wells believes that in all cases of cancer the extremely gloomy prognosis for both mother and child warrants the physician in making the radical operation until at least the sixth month of pregnancy. When the conditions are favorable vaginal hysterectomy is best. When the disease is more advanced or the body of the uterus is larger, Werder's method is advisable. Here the ovarian and uterine arteries are tied through an abdominal incision and the uterus freed from the bladder and broad ligament without cutting through the vaginal wall. The vagina is then freed from its attachments by blunt dissection as far down as is thought advisable, and the uterus drawn down and out through the vulva by stout traction forceps. The peritoneum is then united over the fundus, the abdominal wound closed, and the operation completed by removing the uterus after dividing the vagina at the point selected. This method avoids any contamination of the peritoneal cavity or of any cut surface by septic or cancerous matter. When the fetus is viable at later stages of pregnancy cesarean section with immediate removal of uterus and vagina is indicated. In cases of ovarian cysts, fibroids, or other obstructions, Wells is of the opinion that cesarean section by modern methods will save more lives than forcible dragging of the child through the pelvis. If discovered early in the pregnancy these growths should be removed, for his experience is that during pregnancy abdominal operations in general are well borne and, because of the elasticity and succulence of the tissues, are not as difficult as would be supposed. When possible, see that the excretory organs are put in the best possible condition, avoid all unnecessary hemorrhage, and, particularly, use the most rigid precautions against any septic infection. [W.K.]

3.—Marks considers that too much stress is laid upon examining the urine for albumin as an **indication of eclampsia**. He has seen many women go to term with albuminuria without symptoms referable to toxemia. Urea is always found markedly diminished in these so-called true toxemias of pregnancy, or urinemias. He makes a strong plea for a regular and methodic course of urea estimation in all cases instead of, or relegating to secondary importance, the time-honored examination for albumin. In regard to disproportion between the fetal head and the maternal pelvis he believes the only positive indication for interference is the failure of the head to engage. [W.K.]

4.—McLean thinks that **interference with labor** in primiparas is responsible for many serious conditions. The greater duration of labor in primiparas is due to that peculiar physiologic softening-down and relaxation of the soft parts, which occupies many more hours in its accomplishment than in the case of multiparas. If, however, when the forces are apparently normal, the presenting part is arrested at any given point, say, for over half an hour, or, if the soft parts of the mother having once been relaxed and thoroughly moistened with mucus, are becoming hot, edematous, and discolored, the indications are clear for early and efficient assistance. [W.K.]

1.—Shattuck, Warren, and Cobb give a detailed analysis of 24 cases of **typhoid fever in which peritonitis** occurred and was **treated by laparotomy**. They also give the histories of 3 additional cases in which either peritonitis was apparently not present or the case was not certainly typhoid. The article is quite long, but exceedingly valuable. The cases are reported in detail at the end. The early portion consists of the conclusions drawn from them, which are summarized as follows: In many cases, infection cannot be diagnosed until it has become widely spread, and must necessarily be fatal. In these cases abdominal operation is almost hopeless. If the case is mild and the general condition fair, an abdominal operation is readily borne provided no peritoneal infection is present. In a few cases of mild typhoid there may be sudden perforation with severe symptoms, but the symptoms and the process are both localized, although severe, and if immediate operation is performed the chances are good, although general infection may occur in from 1 to 5 hours, and the spontaneous walling off of the diseased process by protecting adhesions is too rare to be worthy of consideration. In most mild cases whether there be perforation or not, the initial symptoms are usually slight, and consist of local pains, tenderness, and spasm, and leukocytosis. These always demand serious consideration. In any case of typhoid fever, abdominal pain should always lead to suspicion of commencing infection of the peritoneum. In all cases of typhoid, particularly in cases of abdominal pain, the leukocytes should be counted frequently, and in the latter condition at least once an hour. When there is rise of white blood-count with pain and local tenderness and muscular spasm, operation is usually indicated and should in all cases be considered. The authors call attention to the fact that in many of the cases they report an operation should have been performed some hours earlier than it actually was. In their statistics at the beginning, they call attention to a few interesting points. Only 17 of the 24 actual cases were due to perforation. One of the others was due to a rupture of a mesenteric gland. Most of the cases were males and nearly all occurred in early adult life. Complications of various kinds were present, but appeared to have little influence upon the course of the disease. In 7 of the cases the symptoms occurred suddenly without any premonitory symptoms. In 14 they came on gradually. In one case a chill was present. The great majority of the cases were imperfectly studied. The leukocytes were not counted, or only counted once, and the records of the physical examinations are extremely unsatisfactory. Bacteriologic investigations were incomplete, and it is not certain that the results, when they implicated the colon-bacillus, were always accurate. Six cases recovered, but in 3 of these no infection was found at the operation. These prove that an abdominal operation in slight or moderately severe cases of typhoid fever is not very fatal. [J.S.]

2.—Cotton reports two cases of **separation of the epiphysis of the olecranon**. In both cases the injuring force seemed to be purely muscular action. The insertion of the triceps is largely on the epiphysis, but a few of the fibers of the tendinous expansion run beyond the epiphyseal line, and it is due to this fact that there was no more considerable separation of the fragments in these cases. In making a diagnosis of this injury, it is to be remembered that the form of the epiphysis differs greatly in different individuals and that the older the patient the proportionately smaller will be the separated fragment. The treatment consists in fixation of the arm in partial extension with massage for 6 or 7 weeks and then cautious, passive and active motion. There is little liability of involvement of the joint, and union of the fragment with the shaft with complete restoration of function should result when proper treatment has been carried out. [O.B.W.]

1.—Deaver believes that the general surgeon is equally as well equipped to perform every operation of gynecology as is the specialist himself, and he urges the application of the principles of general surgery, particularly the extirpation of carcinomatous glands, in the operation of **hysterectomy**. In the majority of cases he favors the abdominal operation; this is the only way in which the diseased glands can be reached, for the superficial lymphatics of the uterus empty into the lumbar glands, while the lymphatics of the lower part of the uterus terminates in the internal iliac glands. It also gives better access for complete removal of all diseased tissue, it lessens the risks of immediate or subsequent hemorrhage, for the hemorrhage can be seen and definitely located, which is not the case if the vaginal route is chosen. Catheterization of the ureters is not an essential part of the operation. The abdominal route also lessens the danger of infection. Deaver doubts the possibility of sterilizing any vagina. Vaginal hysterectomy is applicable only in cases in which the disease is confined strictly to the vaginal portion of the cervix, the cervical or uterine canal, and in which the uterus is freely movable. In cases in which there are adhesions fixing the organ, or in which there has been inflammation or fixation of the appendages, the abdominal operation is safer, easier and a more rational procedure. Any enlargement of the uterus increases the difficulties of the operation and offers another objection to vaginal hysterectomy. [M.B.T.]

2.—In closing, Bullard draws the following conclusions: There exist certain nontraumatic cases of **increased intracranial pressure** of unknown or doubtful origin. Whenever such an excess of intracranial pressure exists as to cause serious symptoms, the question of its relief by opening the cranium and cutting the dura should always be considered. This is also true in cases of acute severe optic neuritis of unknown origin. In certain non-traumatic cases of excessive intracranial pressure, more or less permanent relief—or even cure—may be obtained by proper surgical intervention. [M.B.T.]

3.—Sackrider gives some excellent suggestions with regards to the management of **typhoid fever**, without adding anything specially new. He advocates the early use of intestinal antiseptics and reduces temperature by the use of cold water enemas and cold sponging. [M.B.T.]

1.—A man of 58 had suffered for about 9 years with some difficulty in swallowing, caused by an **esophageal pouch**. This filled with the first food swallowed at a meal, but could be partly emptied by muscular effort after eating. In 3

years it had doubled its capacity and operation was decided on. Atropia was given hypodermically to keep the mouth and throat dry and it acted admirably; the esophagus was exposed by a 4 inch incision along the anterior border of the sternomastoid muscle. After blunt dissection between the esophagus and vertebra, the attachments of the pouch were found and separated. In order to locate the opening definitely a probang was passed into the pharynx; the fundus of the pouch was opened and spread by hemostatic forceps; the pouch seemed to be a prolongation of the mucous membrane through the muscular fibers of the pharynx and esophagus; it was removed by cutting the isthmus close to the pharyngeal opening and the mucous membrane was inverted and sutured with interrupted catgut sutures. Discomfort from expectoration of mucus and pain from swallowing gradually disappeared and on the tenth day the wound was entirely healed. In a second case a woman of 54 complained of difficulty in swallowing and regurgitated her food, sometimes several hours after eating; she had lost considerably in flesh and strength. A probang was arrested 7 inches from the incisor teeth; no tumor could be detected in the neck. The sac was dissected out through a 5-inch incision along the anterior border of the left sternomastoid muscle; the base of the pouch was attached to the posterior surface of the esophagus and lower border of the pharynx. The pouch was about the size of half a hen's egg and had an opening which easily admitted the tip of the index finger; there was constriction at the site of the pouch. To enlarge the constricted esophagus a considerable circular margin was left about the opening of the sac, the lower portion of the margin was brought downward, placed in the gap made by the divided posterior surface of the narrowed esophagus. The mouth of the pouch was then closed by interrupted Lambert sutures. At first, after the operation leakage occurred of about half the quantity of food swallowed, but the wound closed slowly and the woman is now in perfect health. [M.B.T.]

2.—Rogers believes that **stenosis of the larynx** after diphtheria is less likely to follow intubation than tracheotomy. The etiology, according to O'Dwyer, is very careless or unskilful insertion of poorly constructed or improperly fitting tubes. Rogers considers this incorrect, however, and he believes that the most common cause of stenosis is hypertrophy of the subglottic tissue accompanied by chronic inflammation; intubation is in no way the cause of this, as it occurs irrespective of the operation; less often there is ulcer and subsequent formation of cicatricial tissue; this is unavoidable in certain instances. In the treatment of this condition tracheotomy may be necessary and then the larynx may be dilated with sounds passed from below upward. A tube is then inserted and it is increased in size as soon as the tissue has yielded. Whether stenosis is dependent upon hypertrophy or cicatricial tissue, whether it originally accompanied intubation or not, marked improvement may be expected and a cure may result in from 5 to 6 weeks. Metal tubes can not be used as they soon become roughened and may cause ulceration. Hard rubber tubes are the ideal and they may be worn for an almost indefinite time. Rogers believes that as diphtheria antitoxin comes into earlier and more general use the need of intubation for acute stenosis will gradually disappear. [M.B.T.]

3.—A **perforation** of the anterior wall of the stomach resulted from a gunshot wound just at the left of the ensiform cartilage. On opening the abdomen another perforation was found in the posterior wall along the greater curvature near the pylorus and also one in the hepatic flexure of the colon. The wounds of stomach and intestine were closed by Lambert sutures. Delirium tremens developed and the patient died. The abdomen was found perfectly free from inflammation at the necropsy and the wounds firmly united. In a second case a stab wound resulted in perforation 2 inches long in the anterior wall of the stomach; the wound was closed, the abdomen was cleansed and drainage was provided, but the patient never rallied and died 12 hours later. In a third case, a woman of 32 was suffering from spasmodic stricture with secondary esophageal dilation. By the use of bismuth solution an x-ray photograph was taken which showed that the esophagus was elongated and dilated with a horizontal portion resting upon the diaphragm. On opening the abdomen, the stomach was found much diminished in size and there were between 3 and 4 inches of esophagus below the

diaphragm. **Gastrostomy** was performed by the Sabana-jew-Frank method. Six weeks later the external opening constricted from development of a keloid; this was dissected away, but recurred and was again removed. The patient is now in good general health and has not suffered since the time of operation. In a fourth case a boy drank caustic potash solution by mistake and a few days later difficulty in swallowing resulted. An unsuccessful attempt was made to dilate, but as the patient lost flesh and strength rapidly gastrostomy was performed. The boy has since gained considerably in flesh and strength and can swallow semisolid food. In a fifth case a man of 45 had suffered from severe gastric symptoms for 18 months, he was much reduced in flesh and weak, a nodular tumor involved the region of the pylorus and on opening the abdomen it was found that the mesenteric glands were affected. Anterior **gastroduodenostomy** was performed. After the operation there was rapid improvement and the patient returned to his work; he failed and died as the result of extension of the disease 18 months later. In a sixth operation of the same character as the previous one, the patient survived the operation only 6 weeks, vomiting and loss of strength, resulting from regurgitation of intestinal contents. In a seventh case a woman of 26 entered the hospital complaining of pain in the epigastric region, with rapid loss of flesh and strength. Vomiting followed within a few hours after taking food, and she had become reduced almost to a skeleton. A median incision was made; the tumor was freely movable, and as there was no evident involvement of surrounding structures, **gastrectomy** was decided on. The pylorus was clamped and divided, and the esophageal opening was also divided close to the cardia, after ligating the omental attachments along the curvatures in small sections. End-to-end anastomosis was then performed with interrupted sutures. The operation lasted 50 minutes and was followed by slight shock. Rectal feeding was given for 5 days, progressive improvement followed, and the patient gained between 30 and 40 pounds in 6 months after the operation. A little over a year after the operation she gave birth to a healthy child; during her pregnancy there was evidence of abdominal trouble, and after recovery from confinement an exploratory operation was performed. The gallbladder and transverse colon were found involved by recurrence of the carcinoma and death followed from this cause, 21 months after the operation. [M.B.T.]

4.—A woman of 44 had noticed numbness and tingling in the ring and little finger of the right hand 9 months previously; a soft globular tumor, about the size of a hen's egg, was found in the neck. Expansile pulsation synchronous with the heart-beat and a distinct bruit gave the diagnosis of **aneurysm**. A curved incision was made with the convexity downward just above the suprasternal notch and ending about 2 cm. above the deltoid tubercle of the clavicle; **ligation of the first portion of the right subclavian** was then performed with the use of 3 formaldehyd catgut sutures. The aneurysm involved the entire third portion of the artery slightly encroaching on the second portion. An anomalous position of the subclavian vein above the artery throughout its whole course gave rise to some difficulty; the vein was torn while endeavoring to retract it downward and some time was lost in controlling the hemorrhage. Primary union followed the operation and the pain in the arm and hand completely disappeared. [M.B.T.]

5.—A man of 63 years, while riding in a spring wagon, was thrown to the ground by the wheel sinking into a rut; he fell on his right elbow, and after the injury great increase in the breadth of the elbow was noticed; the olecranon could be felt to the outer side of the external condyle, the condyles and articular surfaces of the humerus could be felt downward and to the inner side of the radius and ulnar. A **complete outward dislocation of the elbow** was diagnosed and confirmed by x-ray photograph. Attempts at reduction were unsuccessful until the muscles had been separated from the external condyle and the triceps was cut across, when the bones easily resumed their natural relation. The arm was put up in a slightly flexed position, and suspended. The patient returned home in 4 weeks with a limb in a useful position with a considerable range of passive motion, but without much active motion. [M.B.T.]

6.—A woman of 25 complained of a severe pain in the left shoulder-blade, with cough and profuse expectoration. There appeared to be a collection of pus on the left side and

on incision a considerable quantity was evacuated. Diseased bone was found and scraped and a discharging sinus resulted; from the sinus escaped pus which contained small granules, and on microscopic examination **actinomycosis** was diagnosed. Death resulted some months later. At necropsy the right **lung** was found adherent laterally to the chest-wall, left lung was adherent posteriorly and at the apex anteriorly. On breaking up adhesions the sinuses were found to connect with the lungs. A careful pathologic report by Professor Flexner is given. [M.B.T.]

7.—A young woman fell down stairs scratching the inside of the right thigh. A few nights later she awakened with severe pain in the leg and discovered a black spot in the skin. She entered a hospital and was treated for 3 months, during which time several spots appeared on the same leg. No change in the condition was noticeable 10 months after the beginning of the trouble. The areas broke down and ulcerated and then would heal; the attacks generally began with an outcrop of vesicles which coalesced and resulted in death of the tissue. During one year there were 31 such attacks. Iodid of potassium, mixed treatment, nutritive tonics, nervous sedatives, and antituric acid treatment were all tried without avail. The pelvic contents were examined without finding any cause of **reflex irritation**; skin grafting was followed by a good result, but the new skin soon lost its vitality. Nerve-stretching of the anterior crural nerve was tried and later resection; all these measures were without favorable results. Amputation at the hip joint was done, but 2 months later a slough appeared on the left thigh over the patella and on the stump. No pathologic explanation seemed possible and the disease is believed to be of central origin. [M.B.T.]

8.—A physician, 34 years old, was thrown from his wagon in a runaway and fell, striking the left hand. A dislocation of the left shoulder was reduced under anesthesia, but pain along the entire length of the arm was continuous, and on rotating the arm with the finger in the axilla, a splintered piece of bone could be felt near the inner tuberosity. A diagnosis of **fracture of the anatomic neck of the humerus** was confirmed by the x-ray photograph. The pressure of the head of the bone caused irritation of the circumflex and musculo-spiral nerves, thus accounting for the pain. The bone was removed under anesthesia and rapid recovery followed. [M.B.T.]

5. I. Points of Practical Interest in Surgical Gynecology.—II. Some Pitfalls in Gynecologic Diagnosis. H. MACNAUGHTON JONES.
6. A Case of Cerebrospinal Fever—Purpuric Variety. WILLIAM FREW.

1.—Cobbett gives interesting tables in his article that show the relation of notifications of and deaths from **diphtheria** from 1839 to 1899, before and after the introduction of antitoxin. The statistics are taken from the health-reports of London, Edinburgh, Glasgow, Liverpool, Manchester, Birmingham, Leeds, Bristol, Newcastle-on-Tyne, Paris, and Berlin. The tables show that there has been a remarkable fall, both in the diphtheria death-rate and case-mortality since 1898. The commencement of this fall was coincident with the introduction of antitoxin. The fact that diphtheria is not spread by bad drains and unsanitary surroundings, as was formerly thought, but by direct transference of the bacillus from mouth to mouth, needs to be forcibly impressed upon all. As measures designed to stamp out the disease the author recommends: 1. The bacteriologic examination of all suspicious cases of sore throat and the throats of all persons who come in contact with patients suffering from the disease. All persons in whom the diph-

theria-bacillus is found should be isolated until the cultures give negative results. 2. All persons recovering from diphtheria should be isolated until the specific microorganism has disappeared from their throats. 3. Whenever diphtheria breaks out in an institution of any kind all the inmates should be submitted to the bacteriologic test, and those that give positive results should be isolated. 4. Every effort should be made to prevent mouth-to-mouth infection in schools. 5. Every town should have a competent bacteriologist. [J.M.S.]

2.—In the treatment of ringworm of the scalp Jamieson gives the following details: 1. The hair must be kept shaved or cut from the entire scalp until the cure is complete. 2. The scalp must be kept rigorously clean by washing twice a day with superfatted potash soap and warm water. 3. The following application may be used: 1 dram of precipitated sulphur, 10 grains each of salicylic acid, Beta-naphthol and ammoniated mercury, and 1 ounce of lanolin. This ointment should be rubbed into the scalp slowly and carefully for 10 minutes twice daily. [J.M.S.]

3.—By the term cross-infection we usually understand the contraction of a second infectious disease by a patient already under treatment for one of the other diseases of the same class. In the City Fever Hospital of Edinburgh during 1899, Ker noted that 3.67% of the 1,034 patients suffering from scarlet fever contracted measles, and that 0.38% contracted varicella. Out of 331 patients suffering from measles 2.4% contracted scarlet fever, and out of 147 patients sick with diphtheria 27% took scarlet fever. These cases of so-called cross-infection do not originate in the hospitals but are imported infections. The condition may arise from the fact that a wrong diagnosis was made before entrance to the hospital; because the patient was suffering from two diseases when admitted, only one of which had been diagnosed; or because a patient was admitted with one disease while incubating another. [J.M.S.]

5.—Jones discusses the pitfalls in gynecologic diagnosis. In pelvic and abdominal surgery we have not only to satisfy ourselves as to the presence of some gross lesion in any particular organ, but we must also determine before operation, if such be decided upon, the nature and extent of the complications that may seriously affect or impede it. He emphasizes the point that pain, in affections of the adnexa as of the uterus, is a symptom which is most deceptive, both in diagnosis and prognosis. The various errors liable to be made in diagnosis are noted. We are liable to mistake other tumors or swellings for mobile kidneys. There are two conditions which may complicate the presence of an abdominal tumor and considerably increase the difficulty of diagnosis—the presence of ascites and pregnancy. Another not uncommon and yet most serious error is that of mistaking the earlier symptoms of appendicitis for inflammation of the adnexa and pelvic peritonitis. Fatal errors have arisen from this mistake, with the consequence that perforation occurred from a fulminating appendicitis before operation was proposed. Perhaps no form of pelvic disease opens so many possibilities of error to both physician and surgeon as ovarian cystoma. Even assuming that we are correct in our differentiation of a true ovarian cyst, apart from a simple cyst of the parovarian, we have in our preliminary examination to decide as to its nature, whether unilocular or multilocular, whether benign or malignant. This assumption, however, removes at once some 50 or more abdominal conditions, each of which so far simulates ovarian cystoma as to have led to operative errors as a consequence. These are the more frequently occurring complications to be determined: ascites, pregnancy, ectopic gestation, cystic or other disease in the kidney, spleen, or liver, uterine myoma, supuration in the cyst, and extensive adhesions. [W.K.]

6.—Frew reports the case of a girl, aged 8 years and 4 months, who was found in collapse in bed one morning after having been ill for about 3 days with sore throat and fever. The patient was restless, had a dazed and stupid look, and a general ghastly appearance. There was a copious purpuric eruption over the face, legs and arms. The patient vomited, passed urine involuntarily, and at one time presented a temperature of 106°. Later, the head became retracted, the vertebral column was curved in a position of opisthotonos, there were coma and delirium. The patient recovered under treatment. A diagnosis of cerebrospinal fever, of purpuric variety, was made. [J.M.S.]

1.—Well-recognized causes of climacteric hemorrhage are carcinoma of the portio, of the cervical mucous membrane, or of the body of the uterus; more rarely, the presence of polyps, or sarcoma of the uterus. But when none of these causes are present there may occur persistent hemorrhage. This has been ascribed by some authors to "hyperplasia uteri" preclimacteric, by others to the softening of the uterine tissue and obstruction in the vicinity of the vena cava ascendens, or to the atheromatous condition of the bloodvessels. Theilhaver, however, is of the opinion that in many cases of preclimacteric hemorrhage the cause is not the condition of the mucous membrane, nor the changed constitution of the bloodvessels, nor abnormal function of the ovaries; but is the abnormal condition of the uterine muscle which, through greater or less relaxation, will not contract sufficiently to counteract the hemorrhage. At the menopause, or in the postclimacteric period, there is present an atrophy of the muscles and a considerable stenosis of the vessels, hence the uterine muscle is not in a condition to counteract the hyperemia, and there occurs in consequence of the atony of the uterine muscles an overflow of blood and persistent menorrhagia, a condition analogous to "subinvolution uteri postpuerperalis." To this same cause, the atony of the muscles, may be due the menorrhagia of the young, in whom the uterine muscle is not yet fully developed; also hemorrhage in the chlorotic, or those convalescent from severe illness. [W.K.]

2.—Ott reports 2 cases of embolism of the mesenteric arteries. The first patient was a man 42 years old, suffering from mitral regurgitation. The embolism occurred with prolonged chill, preceded by vomiting and accompanied by severe pain in the abdomen, cyanosis, and extremely rapid pulse. Diarrhea set in, the stools containing mucus and blood. About $\frac{1}{2}$ of a liter of blood was discharged by the bowel. There were also symptoms of pulmonary infarction—dullness, rales, bronchophony, and slight friction. Characteristic sputum did not, however, develop. The patient gradually improved. In the second patient, a man of 50, who had no heart lesion, but a left-sided hemiplegia, severe pain developed in the hypogastric region. The stools contained blood in large amounts. The hemiplegia gradually improved, as did the other symptoms, the blood disappearing from the motions after a few days. The author believes that in the first patient the embolism was due to the **dislodgment of an intracardiac thrombus**, thrombus in the heart-chambers having been favored by the very poor heart-action. In the second patient the source of the embolus was not clear. There was no evidence of Bright's disease, but clear indications of arteriosclerosis. The embolism was ascribed to the atheroma of the aorta and large vessels. Gerhart and Kussmaul consider as diagnostic of mesenteric embolism demonstration of the source of the emboli, hemorrhage from the intestine, sinking of the body temperature, severe abdominal pain, distention and tympanitis of the abdomen, a possible exudate in the peritoneal cavity, antecedent or contemporaneous embolism in other parts of the body, and the discovery of distended mesenteric folds through the abdominal wall on palpation. The author believes that the fall of temperature is not important and that the infarcted mesentery cannot generally be felt. Regarding treatment, in the first case, in which an insufficiency of the heart-muscle was the cause of the embolism, the vessels being intact, the chief indication was to increase the arterial pressure in order, if possible, to overcome the

obstruction. This was done with camphor and digitalis. In the second case, an account of the condition of the vessels caution was necessary. Stimulants were used, but only in the quantity requisite; a little sherry was all that was given. The use of cold to the abdomen is usually inadvisable, as it may stimulate peristalsis, but it may at times be employed. [D.R.]

3.—**Schmidt's test for bile** which Schorlenmmer employed in his investigation is performed as follows: Two or three particles of fresh feces are rubbed up with concentrated watery solution of corrosive sublimate in a glass dish. After standing covered for 24 hours the material is examined macroscopically and microscopically for the presence of greenish particles. Bilirubin is colored green by this test; hydrobilirubin, red. Nothnagel had postulated the statement that the presence of unaltered bile-pigment in the feces in disease points to the participation of the small intestine in the morbid process. Schmidt examined a large number of normal and pathologic feces, and came to a different conclusion. He found that even in disease limited to the colon bile could be present in the feces. The bile was usually attached to mucous particles of different kinds, more rarely to muscle remains, shreds of fibrous tissue, etc. Nothnagel considered the presence of certain forms of mucus in the feces, particularly the so-called yellow mucous particles, as characteristic of catarrh of the small bowel. Schmidt, however, found that these yellow particles did not consist of mucus, but of albuminous substance, and that therefore they had no significance. In disease of the small intestine it is only the very tiny particles and shreds intimately mixed with the feces that are of importance diagnostically. Many of these are demonstrable only with the microscope. At times they are seen to be partly-digested cells. It is the presence of such **partly-digested cells** that is more indicative of origin from the small bowel than are bile-stained particles. [D.R.]

4.—**Ichthalbin** is a compound of albumin and ichthyol. It exerts a favorable influence upon nitrogenous metabolism, and is a valuable intestinal antiseptic. It may be given to children in place of calomel when an antiseptic action is desired, without accompanying purgation. [D.R.]

5.—**Dormiol** is a compound of chloral and amylene hydrate. It is a valuable, low-priced hypnotic. Its initial dose is .5 gram ($7\frac{1}{2}$ gr.). Its soporific effect manifests itself in from half an hour to an hour after administration. [D.R.]

6.—**Tannopin** (tannon) is a condensation product of tannic acid and urotropin. It is a useful astringent in acute diarrheas. It is tasteless, but its great disadvantage is its high cost. The dose for children is .5 gram ($7\frac{1}{2}$ gr.); for adults, 1 gram (15 gr.). [D.R.]

7.—The patient whose case was described in the last number of this JOURNAL also had attacks of vertigo and diplopia, the attack lasting no longer than a minute, and apparently due to paralysis of the right external rectus. Schultze looks upon the condition as a periodic abducens-palsy, considers it an **epileptic equivalent**. Another interesting case is cited—the patient, a young girl, was subject to typical epileptic attacks—some of them were preceded by peculiar actions. She would lift her clothes and expose her person without the slightest sense of shame, and would try to devour excrement if within reach. Some attacks were inaugurated by another type of *dura*—a brief period during which she indulged in religious or metaphysical speculation. Why is there a God? Is there a God, a heaven, a hell? At times these peculiar phenomena occurred without leading to a convulsive seizure. They are under such circumstances true equivalents of attacks. A third patient, who also had typical epilepsy, was liable to attacks, during which she suddenly grew pale and passed urine involuntarily. She was conscious of what was happening. At times the condition was followed by a typical convulsion, after which the patient remembered neither the *dura* nor the attack. Another patient, of neurotic stock, shot himself through the skull in the temporal region in a suicidal attempt. Speech was at first affected, but improved gradually. Later he developed typical epileptic attacks. After one of the first seizures he complained of a peculiar sensation in the face, and it was proved that the regions of the first and second branches of the left trigeminus were entirely anesthetic. This anesthesia lasted a few hours, and would occasionally precede the convulsion. Schultze believes that the bullet injured the affected branches of the

fifth nerve. Whether the epilepsy is to be viewed as reflex, or as itself of traumatic origin, or whether the epilepsy is idiopathic, the author is unable to decide. The patient also suffered from *folie de toucher*. [D.R.]

1.—v. Bruns says that the prognosis of wounds made by modern small caliber rifles is much more favorable than is the case with the older weapons, and that the treatment should be of a conservative nature. This is especially true of perforating wounds of the abdomen, in which rest and expective treatment generally results in a cure, but laparotomy, conducted under such circumstances as are always present at the field hospital, is almost invariably accompanied by a fatal result. [G.B.W.]

2.—See editorial columns, June 16.

3.—**Pes valgus** is characterized by the foot returning to its normal form as soon as the weight of the body is taken off. It differs from flat-foot in that the arch of the foot is still retained even when the weight of the body is thrown on it. The deformity consists in marked pronation and abduction of the anterior part with extreme prominence of the internal malleolus, a condition which simply is an exaggeration of the normal position of the foot when supporting the weight of the body. The symptoms produced by this condition are rapid tiring on walking, often accompanied by more or less severe pain in almost any part of the foot. The development of pes valgus is in the great majority of cases due to badly-shaped shoes and especially to high heels. There is present in these cases a weakening of the tibialis posticus muscle and very often an actual passive lengthening of the tendon. Hoffa reports a case in which he shortened this tendon and obtained a brilliant result. [G.B.W.]

4.—In a previous paper Lanz has shown, by making cultures from wounds, some treated aseptically and others antiseptically, that better results can be obtained by the **aseptic methods**. However, even the very best of aseptic technic at times will be followed by some infection and only the utmost efforts on the part of the surgeon will be rewarded with continued success. The three sources of trouble are the hands of the surgeon, the skin of the patient and the ligature and suture material; the instruments, dressings, dishes, etc., can all be absolutely sterilized by heat. Therefore, Lanz employs only silk sutures and ligatures put up in small glass balls from which they can be used directly without coming in contact with anything except the hands of the surgeon, and uses in septic cases long rubber gloves so that his hands will not become infected with virulent organisms. He ends by stating that he has had a run of 100 cases without the occurrence of a single stitch-abscess or other suppuration, and in these cases only silk was used for the sutures and ligatures. [G.B.W.]

5.—Walcher calls attention to the possibility of operators who practise asepsis, getting so accustomed to considering all their armamentarium sterile that they forget that infection may be produced by contamination of the once sterile gowns and dressings. This contamination may occur either by the touching of some septic object such as a table or chair, or by the settling of germs out of the air or through some carelessness of the nurse or assistant. As a remedy for this possible evil he proposes the **limiting of the aseptic field**; that is, to consider everything aseptic except the towels surrounding the wound, the instruments, the hands of the surgeon and his assistants and the dressings, and when one of

the sterile objects comes in contact with a septic one, either it must be re-cleaned or discarded. [G.B.W.]

6.—Braun says that silk and other sutures made of permeable material, if not removed at an early date cause the stitch-wound to become reddened, and when left in long enough, to suppurate. This infection is not the result of using septic material, but is due to the bacteria traveling down the thread as though it were a drain, subsequent to the operation. Therefore the use of wire suture material and silkwormgut is not followed by nearly as many stitch-abscesses. The best wire for suturing is the aluminum bronze, because of its malleability and its strength, allowing the use of thin wire and the tying of knots as though it was thread. However, the best of all suture material is linen thread permeated with some substance to destroy its absorbing properties. Pagentecher uses celluloid for this purpose. Braun has during the past year used collodion, preparing the sutures himself, and is very much gratified with the results. His method is as follows: Boil and then dry thoroughly, place in ether for 24 hours, then for a few days in a thin solution of collodion, next in a thick solution for the same length of time. It is then drawn through a slit in a cork to remove the excess and wound around a suitable form on which it is allowed to dry. [G.B.W.]

7.—Lauenstein says that during the past 20 years the question of sterilizing catgut has been definitely settled, as there have been a number of methods introduced whereby an absolutely sterile catgut can be produced. If after the use of such sterile catgut infection follows, it must be a secondary one due to contamination from the hands or air before the operation or afterwards from the tissues of the patient, either the skin or mucous membrane. Therefore, it is essential that the greatest care be exercised in the preparation of the gut and that in its use the most rigid asepsis be practised. Both from a scientific and practical standpoint the gut prepared with some antiseptic is better than the purely aseptic material. Now that we are certain that catgut can be made sterile, its property of being absorbed by living tissues makes it the material par excellence for buried sutures and ligatures, and for this purpose it will be superseded only by some absorbable substance which also has the advantage of not being a good soil for development of bacteria and does not swell when moistened. [G.B.W.]

8.—In a large number of experiments Schenk and Zaufal have shown that mechanical disinfection with Schleich's soap alone will not render the hands free from germs, so that it is essential that the washing be followed by some chemical disinfectant. Better results can be obtained when the hands are scrubbed with sand soap as suggested by Sanger and then immersed in a hot 1:1000 solution of corrosive sublimate. The sand soap does not cause any irritation of the skin. The brushes used in scrubbing the hands should be sterilized by boiling in a 1% soda solution each time they are used. The best disinfectant for following the cleansing is a 1:1000 solution of bichlorid as hot as the hands can bear. When heated the germicidal action is much accelerated. [G.B.W.]

10.—Moritz briefly describes a method for ascertaining the proper size of objects subject to diagnosis by the x-rays. It is based on the production of parallel rays by the continued motion of the x-ray tube through a limited area. [G.B.W.]

Revue de Chirurgie.

April 10, 1900. [20me Année, No. 4]

1. Epithelioma of Both Breasts Coincident with Tuberculous Peritonitis. A. LEDENTU and H. MORESTEIN.
2. Excision of the Scapula with Conservation of the Upper Extremity in Malignant Tumors of this Bone. L. PICQUÉ and DARTIGUES.
3. Multiple Pedunculated Uterine Fibroma. F. TERRIER and E. REYMOND.
4. Resection of the Hip. ROSCHET.
5. The Pathology and Anatomy of Carcinoma of the Stomach. B. CUNEO.

1. A case of carcinoma of both breasts is reported occurring in a woman 27 years old; 12 years previously she

had had a general inflammation of both breasts, and when she first came under observation it was thought she might be suffering from tuberculosis of the breasts from the fact that there was, at the same time, evidence of tuberculous peritonitis. There was no enlargement of the axillary glands. Laparotomy was performed, and her condition was temporarily considerably improved. She refused to have the breast excised or even to allow a small specimen to be cut for examination. Death resulted a few months later. Examination by 2 competent pathologists showed that the growth was a cylindrical epithelioma. [M.B.T.]

2.—A woman of 25 had been taken, about 4 months previously, with severe pain in the right arm accompanied by formication in the hand. After a month the pain disappeared completely, but reappeared 3 or 4 weeks later. About this time the patient noticed a tumor of the shoulder; when first examined this tumor had the size of a fetal head, it was hemispherical and the skin over it was a violet color, it seemed to be limited to the posterior surface of the scapula. A diagnosis of osteosarcoma was made and the operation of excision of the scapula was performed. Pathologic examination proved the growth to be sarcoma. A good recovery followed. At present, as a matter of course, all movement of abduction, extension, and flexion of the arm are impossible, but nearly all movements of the forearm, the hand, and the fingers are possible; the external and internal heads of the triceps also prove sufficient for extension of the forearm. The patient is able to write and to do ordinary work even of some delicacy. The methods of operating are quite thoroughly discussed and a table is given of 77 cases in which the operation has been performed; in 36 cases the extirpation was partial, 35 total, and in 6 it was carried out in combination with resection of the head of the humerus. The entire mortality was 15 or about 18%; death resulted from infection in 5 cases; from primary hemorrhage in 5 other cases; as the result of opening the pleura in 1 case; and from bronchitis, aggravated by chloroform in 1 case; in 1 case death resulted from a metastatic growth in the lungs 14 days after operation. [M.B.T.]

3.—A successful case of supravaginal hysterectomy for fibroid uterus is reported and thorough study is given of the pathologic conditions which were found. [M.B.T.]

4.—Rochet advocates resection of the hip by the anterior route according to the method suggested by Olier. From a comparative study of patients operated upon by this method and by the posterior method it appears that healing results more rapidly, and that ankylosis results in a more favorable position. This route also offers better facilities for drainage and the chances of secondary infection are lessened. In a great majority of cases the operation was for suppurative diseases of the hip joint. [M.B.T.]

5.—Cunéo reports the results of studies as to the mode of local extension of carcinoma of the stomach and the involvement of the lymphatic glands. He finds that the disease, particularly in the case of carcinoma of the pylorus, presents 3 peculiarities of great practical importance; the early and extensive involvement of the submucosa, the tendency of carcinoma to invade the lesser curvature and the general preservation of the integrity of the duodenum. The early invasion of the submucosa shows that it is absolutely insufficient to make the incision only a centimeter from the apparent limits of the growth, as tissue which is apparently healthy may have been already considerably infected through the submucosa. The resection should be made as near as possible to the cardia because of the tendency to extend along the lesser curvature; this is desirable even when the lesser curvature appears to be perfectly healthy. The habitually healthy condition of the duodenum makes it unnecessary to remove more than 2 or 3 centimeters. The lymphatics are affected in the proportion of about 84%; the coronary chain is affected early and more frequently than the subpyloric glands. When possible the tumor and the perigastric glands should be removed altogether. The only means of extirpating the coronary glands consists in the greatest possible resection of the lesser curvature; the removal of the subpyloric glands does not generally present any difficulty. In certain patients these glands may be perfectly imperceptible if they are of small size and situated far enough from the greater curvature. As much as possible of the gastrocolic ligament should be removed, taking with it the glands and their afferent lymphatics. [M.B.T.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Mitral Stenosis.—Broadbent (*Heart Disease*, 1900.) writes: When the symptoms are very urgent, venesection may be of striking service, and in certain cases there is no other treatment that will take its place and avert a speedy, fatal termination. The contrast between the powerful right ventricle impulse and the small, weak, irregular pulse, is very striking, and is one of the most important indications for venesection. Venesection does not, however, dispense with the necessity for relieving the portal circulation by purgation. Stimulants which without these measures afford no relief, and may indeed do harm, will then be of the greatest service, and digitalis, and like remedies, will find their opportunity. When the symptoms are less urgent or venesection is objected to, seven or eight leeches applied over the liver may be of service. The administration of digitalis in early stages of the disease is seldom if ever called for; it is only when there are symptoms of right ventricle failure, and then only after free purgation and, if necessary, venesection have been employed, that it should be prescribed. Up to a certain point in such cases its influence is often most beneficial, but sometimes it fails to relieve, and even appears to aggravate the symptoms. If continued too long in cases where it has been of signal service, unfavorable effects may supervene, marked by slowing of the pulse, a sense of precordial oppression and by coupled heart-beats, the first of which alone reaches the wrist, the second being unaccompanied by an aortic second-sound. Digitalis, therefore, must be employed with caution in mitral stenosis and its effects should be carefully watched. Under no circumstances should it be prescribed unless the patient is under observation, and it should rarely be given for a long period of time. Nitroglycerin and other vasodilators may sometimes be given with good effect for many weeks or even months, in conjunction with general tonics, such as iron, quinin and nuxvomica.

Pruritus Ani.—According to the *Practitioner* the following formula is useful:

R.—Sodium hyposulfite	30 parts.
Carbolic acid	5 parts.
Glycerin	50 parts.
Water	450 parts.

Compresses wet with the solution are to be applied frequently.

Cough in Phthisis.—The *Journal des Praticiens* recommends:

R.—Terpin hydrate.....	15 grains.
Codein	1½ grains.
Extract of belladonna.....	1½ grains.
Extract of hyoscyamus	¼ grain.
Mass of cynoglossum	8 grains.

Make into 10 pills. One four times daily between meals.

The Danger in the Administration of Chloroform in the Presence of a Flame.—According to the *Medical Review* (April, 1900), Maurange (*Gaz. Hebdom. de Med. et de Chirurg.*, December 31, 1899) states that the risk of poisoning by the products of decomposition of chloroform administered in the presence of a flame is now admitted. The degree of poisoning is very variable and depends on the decomposition of the vapor which is greater the more prolonged the operation, the larger the number of lighted gas jets, and the more defective the ventilation of the room.

The writer, who has suffered on several occasions, thus describes his sensations. Soon after the administration of chloroform is begun in a close room lit by several gas jets, those present are conscious of a tingling in the conjunctivae, nose, and back of the throat, which rapidly invades the respiratory passages and produces a dry, noisy cough. This cough is not paroxysmal, but is repeated and aggravated at each inspiration till more or less severe dyspnea results, which may make it necessary to interrupt the operation and ventilate the room. The patient appears to suffer less than

others present, and the writer was able by inhaling a few whiffs of chloroform to slightly relieve his dyspnea; this leads him to believe that the action of phosgene on the mucous membrane may be calmed for the moment by chloroform.

The discomfort does not disappear immediately after returning to the fresh air, but an acrid sensation at the back of the throat may remain for the rest of the day, or even the following night. This resembles the sensations experienced after exposure to sulphurous acid or nitrous fumes. Another symptom is marked general lassitude which persists during the day.

In the cases observed by the writer the duration of anesthesia was relatively short—in five cases from 10 to 15 minutes, and in another 25 minutes.

[The product formed from the decomposition chloroform in the presence of a flame has been found to be carbonyl chlorid. Sir Humphrey Davy first described this body and called it phosgene. Its inhalation has in a number of cases excited severe and even fatal pneumonia.]

Organic Silver-Salts in Chronic Suppuration of the Middle Ear.—Gleason (*Laryngoscope*, March, 1900) writes that the most popular of the organic silver-salts are argonin and protargol. As in solution the former is somewhat unstable and when partially decomposed is said to be irritating, his experience has been confined to the latter. In various forms of conjunctivitis, with but few exceptions, he finds that protargol yields excellent results when applied to the palpebral conjunctiva in 5% solution. Solutions of 10% and even 20% may be used in the eye without producing more than transient irritation. In 4 cases of prolonged otorrhea a hypodermic syringe full of a 5% solution of protargol by means of a Blake's canula, was injected as high up into the attic as possible. The parts were then massaged with Siegle's pneumatic speculum in order to force a portion of the solution into more distant parts than could be reached with the syringe. The ear was then carefully dried with cotton. The cures were so speedy in 3 of the cases as to indicate that we have in protargol an antiseptic and astringent superior to any now used in the treatment of chronic middle-ear suppuration, and much more easy of application than any of the powders. Gleason has used the 5% solution in the auditory canal, the atrium, and the pharynx with success in decreasing inflammation and modifying secretion. Unlike silver-nitrate solutions it is nonirritating to the posterior pharyngeal wall. It does not sear the tissues, and hence penetrates more deeply than silver-nitrate solutions, but produces no stain upon the mucous membrane or skin. For controlling hemorrhage, or searing the stump of an aural polypus, protargol is greatly inferior to silver nitrate.

Picric Acid in Chancres.—Hawthorn (*La Semaine Médicale*, No. 13, 1900) has obtained excellent results from the local application of picric acid to chancres both hard and soft. He reports 12 cases in which the action of the remedy was uniformly favorable. He first washes the sore with a camphorated solution of carbolic acid and then applies a moist dressing of a saturated solution of picric acid. The healthy skin must be protected from the application or otherwise an eczematous inflammation is excited. Cicatrization begins in 4 or 5 days, and is completed within a month.

"Chelsea Pensioner."—The following is the formula of the time-honored remedy for chronic rheumatism, which a correspondent has requested us to publish:

R.—Gum guaiac	1 dram.
Powdered rhubarb.....	2 drams.
Potassium bitartrate.....	1 ounce.
Washed sulphur	1 ounce.
Nutmeg	1.
Honey.....	1 pint.

A tablespoonful night and morning.

The formula received its name from the fact that it was originally given by a Chelsea pensioner to Lord Amberst, who is said to have experienced a complete cure from its use.

The Treatment of Exophthalmic Goiter.—Herrick (*New York Medical Journal*, June 16, 1900) states that hyoscin hydrobromate ($\frac{1}{100}$ grain) given over a considerable period of time, and of picrotoxin ($\frac{1}{10}$ to $\frac{1}{15}$ grain) have proved useful.

Original Articles.

TOTAL EXCISION OF THE SCAPULA ALONE, AND
WITH THE ARM (INTERSCAPULOTHORACIC AMPUTATION): PARTIAL EXCISION OF THE SCAPULA FOR TUMOR.

By J. J. BUCHANAN, M.D.,

of Pittsburgh, Pa.

Surgeon to Mercy Hospital.

GENERAL CONSIDERATIONS.—Excision of the scapula, either alone or combined with removal of the arm, is an operation which has been performed only in the present century. Avulsion of the scapula, with the arm, however, according to published records, occurred twice during the last century, and in both instances the patient recovered. The first of these cases was that of a miller, named Samuel Wood, whose *arm and scapula were torn completely from his body* by a rope attached to his mill-wheel and wound around his arm. The accident occurred on the fifteenth day of August, 1737. The following day he was removed to St. Thomas' Hospital, London, where he recovered under simple dressings. The case was reported by Mr. Ferri, who had it in charge, and was recorded by Cheselden, in his work on anatomy.¹

Notwithstanding this exhibition of the toleration of this severe traumatism, more than seventy years passed before any surgeon took courage to remove the entire scapula either for accident or disease.

In the year 1808, Ralph Cuming, an English naval surgeon, stationed at Antigua, *removed the arm, scapula and clavicle* for gunshot wound. The patient recovered and was examined in England, at the Greenwich Hospital, by Copland Hutchinson, by whom the first record of the case was made.²

There is no account extant of any attempt to remove a part of the scapula for new-growth till 1811, when Philip von Walther, after repeated trials on the cadaver, undertook to remove the subspinous portion of the body of the bone for a spongy growth. After uncovering the growth, ligating numerous vessels and exposing the lower angle of the bone, he was obliged to abandon the operation on account of the collapsed condition of the patient, who died 14 days later of purulent infection and exhaustion.

The first completed operation for removal of a considerable part of the scapula for morbid growth was performed by Liston, of Edinburgh, in 1819. The growth was malignant and was removed successfully, together with the inner two-thirds of the bone. On account of a rapid recurrence, Mr. Liston proposed to extirpate the remainder of the scapula and the arm, but could not get the sanction of any of his colleagues to this procedure, and, therefore, desisted, and the patient died a few months later.

The first operation for removal of the entire scapula together with the arm, for morbid growth, was successfully performed in 1836, at the village of Plymouth, N. H., by Dixie Crosby, then resident of a town now known as Laconia, of the same State.

The first total excision of the scapula, subsequent to disarticulation at the shoulder, was made by Mussey, of Hanover, N. H., in 1837. This case has been frequently quoted as an instance of the success of repeated operations in malignant disease. Nineteen years before this operation, the patient had had a metacarpal bone

removed; and six years before had undergone a disarticulation at the shoulder for a recurrence. Thirty years after the removal of his scapula and clavicle, this man was living and free from recurrence.

After Liston's operation, in 1819, a number of partial excisions for tumor were performed, including Skey's operation in 1830, in which the entire bone was removed, with the exception of the glenoid process.

Till the year 1847, no one seems to have considered it possible to remove the entire scapula and preserve the usefulness of the arm. In this year, Reid, of Jena, urged the propriety of removing the entire scapula in proper cases and preserving the arm, but no case suitable for operation presented itself in his practice.

It remained for von Langenbeck, in 1855, to make the first total excision of the scapula, preserving the arm. His patient, a boy of 12 years, the subject of malignant disease, died about three and a half months later of recurrence, and there is no record of the usefulness of his limb during that period.

The second total extirpation of the scapula with preservation of the arm was made in 1856 by James Syme, of Edinburgh, without previous knowledge of the case of von Langenbeck. Syme's patient, a woman of 70 years, died of senile decay two months after operation.

These are the cases which mark epochs in the development of scapular excision, an operation whose history is almost coeval with the present century, in the first half of which the principles and limitations of the operation were established, in the second half of which these principles have been modified and the operation extensively practised.

LITERATURE.—The literature of operations on the scapula is very extensive and is largely made up of German and French inaugural theses and reports of cases. The first important statistical paper on the subject was written by Dr. Stephen Rogers, of New York,³ and has been justly praised by many who have since written. The most valuable and exhaustive contribution yet made to this literature is the paper of Dr. George F. B. Adelman, of Dorpat,⁴ read before the Seventh Congress of German Surgeons in 1878. This paper is a marvel of research and accuracy, and was supplemented by another by the same author on June 4, 1888, just 11 days before his death.⁵ The most complete work yet written on removal of the scapula together with the arm is by Paul Berger, of Paris.⁶ This monograph has received uniform commendation from every subsequent writer on the subject, and is remarkable for its historical accuracy, its logical arrangement and the formulation of rules of operative procedure which have been almost universally observed since its publication.

A reference to the bibliographic column of the tables in the present paper will show the very large number of articles that have been written on excision of the scapula. Most of these have had for a motive the recording of cases personal to the authors, to which has been added in many instances a more or less complete statistical history of the operation.

CLASSIFICATION OF CASES.—Authors differ widely in their grouping of scapular excisions. The following arrangement of cases seems most natural and satisfactory:

I. Total excision of the scapula with simultaneous removal of the arm. (Interscapulo-thoracic amputation.)

II. Total excision of the scapula subsequent to disarticulation at the shoulder-joint.

III. Total excision of the scapula, at one operation, with preservation of the arm.

IV. Total excision of the scapula, at two or more operations, with preservation of the arm.

V. Partial excision of the scapula, for tumor.

VI. Partial excision of the scapula with simultaneous removal of the arm.

A chronological order has been observed in all except group V. The cases in this group differ so widely from each other that no satisfactory deductions could be made were they arranged merely according to date. They have therefore been grouped according to the amount of bone removed, with a subgrouping according to priority of occurrence.

Those operations only have been considered total excisions in which the entire bone with all its processes has been removed. This is contrary to the custom of most writers, who have included among the total excisions all cases in which the bone was nearly all removed.

Partial excision for causes other than morbid growth have not been considered. This will account for the omission of a considerable number of operations for injury, necrosis and tuberculosis, recorded by nearly all writers as total excisions, but in which one or more processes or cartilaginous borders were left behind.

GROUP I.

GENERAL REMARKS.—Total excision of the scapula with simultaneous removal of the arm has received a variety of names: Extirpation of the scapula and arm (Veit); total ablation of the upper extremity with scapula (Sambucy); amputation of the upper extremity in the contiguity of the trunk (Berger); interscapulo-thoracic amputation (French writers); removal of the entire upper extremity (Chavasse); amputation of the entire upper extremity (Treves); operative removal of the bony breast-girdle (v. Adelman); removal of half of the shoulder-girdle (v. Eiselsberg); extirpation of the shoulder-girdle (Küster); extirpation of the shoulder (Nasse); extirpation of the scapula and humerus (Doll and Keller); exarticulation of the arm with the shoulder-girdle (Kocher); amputation of the fore-quarter (Paton).

The first operation of this kind is generally attributed to Ralph Cuming (1808); the question of its authenticity has been touched on in the first part of the present paper. No similar operation was performed thereafter till 1836, when Dixie Crosby, Professor in Dartmouth Medical College, successfully removed the arm, scapula, and clavicle (or perhaps a portion of it) for a malignant growth, 37 inches in circumference, in a patient worn down by suffering and emaciated to the last degree. The details of this case were collected and a complete record of it made by the operator's son and successor, Prof. A. B. Crosby.¹ This patient was exhibited in June, 1836, before the New Hampshire State Medical Society. To the publicity given to this case was no doubt due the performance of the next operation of the same kind, by Dr. Amos Twitchell, of Keene, N. H., two years later, as well as Mussey's operation for removal of the scapula subsequent to disarticulation at the shoulder, also the first one of its kind.

It is an interesting fact that both Drs. Twitchell and Mussey had been consulted by Crosby's patient and had advised against the operation, considering it impracticable.

The operation of Twitchell was followed in a very few months by that of McClellan, of Philadelphia; and these three American surgeons had no followers in the performance of this operation for malignant disease during the next 24 years.

During this time, the operation was performed six times for injury, in different countries. This brings its history down to the year 1862, with a record, during the preceding 54 years, of 10 cases.

During the next 20 years, or until the general advent of successful antiseptic with corrosive sublimate, in 1881, 19 new cases were added to the list (14 for growth and 5 for injury). Of the 29 operations done in the 74 years prior to the beginning of successful antiseptic, 11 patients died, (38% mortality). The effect of antiseptic practice during the next six years became apparent in the increased number of cases (28) and the greatly lessened mortality; 5 patients died (18%).

At this period (1887), was published the monograph of Paul Berger, of Paris, a most admirable and exhaustive treatise. In it he recorded at length the operation which he had performed in 1882, gave a full account of all previous operations and formulated definite rules of procedure. So succinct, definite, and valuable were the rules laid down by him, that the operative method he advised has been generally and very properly called by his name. It should, however, be stated that no part of his operation is original, every act of the procedure having been employed by earlier operators. But Berger's work has given a remarkable impetus to the operation and the advent of asepsis, applied to the definite procedure he advocated, has made it wonderfully successful in its immediate results.

In the 13 years since the publication of Berger's monograph, there have been recorded 124 operations, with 13 deaths (10.5% mortality), and for an operation of this magnitude, this is certainly a very satisfactory showing.

INDICATIONS.—Total excision of the scapula with simultaneous removal of the arm has been performed for a variety of indications:

1. *For injury*, by shot wounds, from pieces of small and large caliber, by explosions, by avulsions, by crushing accidents, especially on railways, by burns, and in one case by the bite of a wild beast.

2. *For neoplasm*, sarcoma, chondroma, and carcinoma. By far the most common growth for which this operation has been performed is sarcoma, periosteal or medullary, springing from the upper part of the humerus or originating from the scapula and involving the humerus or the soft parts (especially the vessels) of the axilla, or implicating the shoulder to such an extent as to preclude the possibility of saving the limb and at the same time extirpating all diseased tissue.

Several operations of this kind have been done for carcinoma, recurrent in the axilla after excision of the breast for cancer, the purpose of the operation being chiefly palliative, to relieve pain and rid the patient of the burden of an edematous limb.

3. *For necrosis following injury*.

4. *For tuberculosis*.

5. *For progressive phlegmon*.

6. *For painful cicatricial stump*.

7. *For gangrene of arm*.

RELATIVE INDICATIONS.—Malignant growth of the upper end of the humerus has been set down above as a positive indication for total extirpation of the scapula with the arm. This is a matter for discussion, as a dis-

articulation at the shoulder-joint might be done, or even a resection of the upper part of the humerus⁸.

The choice between disarticulation at the shoulder-joint and interscapulothoracic amputation in malignant growths of the upper part of the humerus cannot be definitely made till a fair comparison shall have been instituted between the remote results of the two operations in a large number of cases. It is very desirable that this should be done, but it would probably be difficult at present to secure records of many shoulder-joint amputations, for the reason that they are not usually considered of sufficient importance to report. In the absence of satisfactory statistics it may be said for the interscapulothoracic amputation:

1. That the lymphatic vessels and veins are removed at a higher level.

2. That the shoulder muscles, especially the deltoid, and the scapulo-humeral muscles are entirely removed and that they are frequent sites of secondary infection in growths originating in the humerus.

3. That the glands and fat in the axillary and sub-clavicular region are more accessible and more thoroughly cleared.

4. That the resulting wound is much more favorable for primary union than is the stump containing the overhanging acromion and the retreating glenoid fossa.

5. That it is extremely improbable that the statistics of shoulder-joint amputation would show a lower general mortality than appears in Table I, in which the mortality of the last 124 operations was but 10.5%.

6. That the difference in the resulting deformity is insignificant.

7. That an examination of the cases in Table II will show that in a number of instances a disarticulation has been followed by recurrence in the scapula or its muscles, and that in these cases, at least, an interscapulothoracic amputation at first would have been preferable.

These reasons appear to the writer to be sufficient to justify the removal of the scapula and part of the clavicle in every case of malignant tumor requiring amputation at the shoulder.

In considering the treatment of malignant growths involving the bone or soft tissues below the level of the shoulder-joint there must be borne in mind

1. That the arm, being such an important member, no amputation should be considered if there is a fair probability of completely extirpating all diseased tissue without destroying the usefulness of the forearm and hand.

2. That, therefore, early and complete excision is to be advised in every growth of the upper extremity.

3. That malignant growths of any part of the humerus (except possibly the less malignant giant-cell sarcomata) require removal of the entire bone and

4. That, therefore, in all such cases an interscapulothoracic amputation should be performed.

5. That an arm amputated at or above the elbow is of but little service and

6. That, therefore, in every case of malignant disease (except the giant-cell sarcoma) requiring amputation at or above the elbow, an interscapulothoracic amputation should be made as a primary operation.

7. That, considering the great usefulness of a forearm stump and the probability of recurrence under any circumstances, no amputation should be made above the middle third of the forearm unless both bones are diseased or the soft parts infiltrated.

In this connection the opinion of Professor Nicholas Senn should be well considered. In reporting two cases of transscapular amputation at the Chicago Medical Society,⁹ in one of which recurrence had appeared only after 12 years of health, he spoke as follows: "I have for a long time thought that, in the complete removal of the upper extremity, surgeons for many years have gone too far, that is, insisting upon removing the entire or part of the clavicle and the entire scapula. . . . These cases ought to satisfy the members of the Society that, in the future, we must draw a distinct line in performing serious operations between cases in which it is absolutely necessary to remove the entire scapula and part of the clavicle and those in which we can confidently expect to perform a radical operation by resorting to transscapular amputation."

METHOD OF OPERATION.—Berger's method is as follows:

1. Make an incision over the outer two-thirds of the clavicle through all structures, including the periosteum.

2. Separate the periosteum from the middle third of the clavicle.

3. Excise the middle third of the bone.

4. Isolate the subclavian artery as it passes under the bed of the clavicle, tie it at two points and cut between.

5. Elevate the limb and isolate, tie and cut the subclavian vein in the same manner.

6. Start an anterior incision at the middle of the one already made and extend it downward and outward to the anterior fold of the axilla; continue it backward across the inner surface of the arm at the level of the axilla and extend it downward to the lower angle of the scapula. During this portion of the operation the arm should be kept at a right angle to the body.

7. Deepen this incision in front, severing both pectoral muscles and exposing the contents of the axilla.

8. Sever the cords of the brachial plexus at the level of the upper stumps of the vessels.

9. Start a posterior incision at the outer end of the clavicular incision and extend it directly downward over the spine of the scapula and prolong it till it meets the anterior incision at the lower angle of the scapula.

10. Dissect the skin and subcutaneous tissue backward to expose the muscles at the upper and inner borders of the scapula.

11. Cut the attachments of the trapezius muscle, the omohyoid, the levator anguli scapulae, the rhomboidei and serratus magnus, drawing the scapula out from the chest and passing the fingers under the muscles wherever possible as they are cut, controlling with forceps the vessels as they appear, the most important of which is the transversalis colli. This is easily done, as the muscles to which they are attached are held between the thumb and fingers as they are cut.

12. The bone can now be drawn away from the chest, and the entire limb removed by severing such attachments as remain.

13. Tie or twist all vessels.

14. Make one or more counter-openings for drainage tubes.

15. Suture accurately.

The above directions are for typical cases, where the conditions present will permit of following the method exactly. It often happens, however, that the location of a morbid growth, the loss or devitalization of tissue from injury or the position of sinuses and suppurative areas in necrotic and tuberculous cases renders neces-

sary more or less extensive changes in the direction of incisions and the formation of flaps.

The essential elements of Berger's method are preliminary ligation of the great vessels and the formation of anterior and posterior flaps. von Bergmann's procedure differs only in the early steps. He ligates the subclavian artery at the outer side of the scalenus anticus muscle. He then saws through the clavicle at the point of ligation, making but a single sawcut through the bone.

In the two personal operations recorded in the present paper, a slight modification of Berger's method was made. The primary incision was made and the middle third of the clavicle removed. A portion of the anterior incision was then made from the middle of the clavicular incision downward and outward over the anterior axillary fold to the inner surface of the arm at the level of the axilla. This incision was at once deepened, severing both pectoral muscles and exposing the axillary vessels and nerves for a considerable distance.

The surface of the vessels was then cleared upward till the level of the clavicle was reached. They were then cut between ligatures at this level. The advantage of this modification is that there is no difficulty whatever in isolating the vessels; for the wound is a long one, is almost parallel with their course and they are completely and widely exposed by the section of the overlying pectoral muscles.

Embarrassment from hemorrhage in securing the vessels by Berger's method has been noted by Keen, Chavasse, and Macnamara. This cannot occur if the vessels are exposed first below and cleared upward to the point of ligation. It is true that in some cases this cannot be done, by reason of the overlying tumor; but it is advisable to do it whenever the conditions are favorable.

DR. BUCHANAN'S CASE I.—*Interscapulothoracic Amputation for Recurring Sarcoma of Upper Arm. Recovery.*

Philip L., aged 69 years at time of operation, was referred to the writer by Dr. J. C. Hierholzer of Allegheny, in July, 1898. He had then a soft, globular growth about 16 inches (40 cm.) in circumference with a comparatively broad base, springing from the neighborhood of the insertion of the deltoid muscle. A diagnosis of sarcoma was made and the removal of the limb advised, provided it should be found to involve the bone. He declined the operation on these conditions, but finally consented, with the understanding that amputation was to be done only as a last resort. On August 7, 1898, the growth was excised and was found to have its origin in a small area of periosteum about the insertion of the deltoid. A portion of this muscle was involved and was removed, together with a large area of integument—about one-half the circumference of the arm and about 4 inches (10 cm.) in length.

Operations for recurrence were done on December 17, 1898, and February 25 and April 18, 1899, the last taking away the entire biceps below the seat of the original growth and most of the coraco-brachialis. The rapid and extensive recurrence finally convinced the patient that nothing short of the loss of his arm would give him any chance for his life, and he consented to lose the arm, together with the scapula and its muscles, which as yet showed no sign of involvement.

Accordingly, on August 7, 1899, he was anesthetized with chloroform at the Mercy Hospital, and the operation of Berger performed, with two slight modifications: (1) The anterior incision was made before the ligation of the subclavian vessels, and the vessels were exposed under the severed pectoralis muscles and followed up from below to the point of ligation; and (2) the posterior incision was made to follow the spine of the scapula to about its middle before turning down to meet the anterior at the lower angle of the bone.

The former of these modifications is to be recommended;

but the latter, while it has the advantage of removing a greater area of integument, has the disadvantage of making a more complicated suture line.

The loss of blood was trifling and the shock unnoticeable. Glass drains were inserted at two points. Primary union was secured throughout. On the third day the patient was dressed and walking about the corridors, and at the end of the sixth day he attended church in Allegheny (about 2 miles from the hospital). He was dismissed from the hospital on the tenth day and has since remained well.

Nature of the Growth.—Dr. J. DeVinne Singley made the following report of the primary growth removed August 6, 1898: "The tissue is composed of large round connective tissue cells, for the most part, with a few spindle cells. There is considerable intercellular substance present. Pathologic diagnosis—large round-celled sarcoma."

DR. BUCHANAN'S CASE II.—*Interscapulothoracic Amputation for Recurring Sarcoma of Upper Arm. Recovery. Recurrence in Lung and Death in 5 Months.*

David L., aged 42 years at time of this operation, first noticed a dull aching in his left arm about 4 years before, which he attributed to the strain of heavy lifting. Eight or nine months later he noticed a small growth about the position of the insertion of the deltoid. Three months after its appearance he had it excised. It soon recurred, and 5 months after the first operation it was again excised by another surgeon. After this it was excised three times by myself, once by my colleague, Dr. R. W. Stewart, and once by a well known surgeon in New York. During the three years since his first operation, the growth was excised seven times.

Prior to his admission for the radical operation he had a cough, and, suspecting metastatic deposits in the lungs, I requested my colleague, Dr. I. J. Moyer, also to examine these organs. Dr. J. H. Reynolds, of Bellevue, made a physical examination, and to neither of these gentlemen were any signs of metastasis clearly evident.

The operation of Berger was performed on September 19, 1899, at the Mercy Hospital. Chloroform was first given and alarming signs of collapse soon appeared. Stimulation was given and ether substituted. This was but little improvement, and throughout the operation the pulse was feeble and the breathing shallow and irregular. So much difficulty was experienced with the anesthesia that much of the operation was done with the patient in a semiconscious condition.

The only variation from Berger's plan was in exposing the vessels below and laying them bare upward to the clavicle, as in the other case.

Primary union resulted throughout the wound and the patient left the hospital for his home in Uniontown with his wound completely healed on the eleventh day.

Metastatic deposits in the lungs soon made themselves evident to physical exploration, and he died on February 27, 1900, a little more than 5 months after operation.

Nature of the Growth.—Microscopical examination of the growth each time it was excised was made by Dr. John DeVinne Singley, pathologist to the hospital, who found it to be a round-celled sarcoma.

- ² Although the case of Cumming has been accepted, apparently without question, by all later authors, its authenticity does not seem to be beyond dispute. The first and apparently the only record of it, is in a letter written by Copland Hutchinson to the *London Medical Gazette*, 1830, 273, apropos of the discussion of Mr. Luke's case of partial excision. Hutchinson states that in 1808 (22 years before), he had examined a patient from whom Ralph Cumming had amputated the arm, scapula and clavicle. It seems strange that Cumming, the author of at least one surgical work and many journal articles, should fail to record an operation of such importance, and that it should go unpublished for 22 years. The authenticity of the case was questioned by a correspondent of the same journal shortly afterward, but no proof to the contrary was adduced.

- ⁸ That cases of myeloid or giant-cell sarcoma of the humerus may be successfully treated by excision of the affected portion of the bone is established by operations such as that of Mr. N. C. Macnamara, of London, who excised the head and neck of the humerus in 1887 for a myeloid sarcoma about as large as an orange. A personal communication, kindly sent by Mr. Macnamara, states that the patient is still (March 11, 1900) free from recurrence and has good use of his limb.

30	Despres, A., of Paris.	June 21, 1882.	M., 22.	Sarcoma.	Recovery.	Recurrence and death in 7 months.	Injury 11 years before. Part of scapula previously removed. Now, remnant of scapula, arm, and one-third of clavicle.	<i>Laugenhagen: Tumors Solida du Scapulum</i> , Paris, 1883.
31	Bergier, P., of Paris.	Oct., 1882.	M., 27.	Enchondroma.	Recovery.	No recurrence 16 years later. (See <i>de Chir.</i> , 1898.)	Enormous tumor of upper end of humerus.	<i>L'Impulsion du Membre Supérieur dans le Contingent du Tronc</i> , Paris, 1887.
32	Heath, C., of London.	July 4, 1882.	M., 16.	Sarcoma.	Recovery.	Two subsequent operations for recurrence and death in 8 years. (Personal communication.)	Enormous growth of upper end of humerus, slightly encroaching on scapula.	<i>Med. Times and Gaz.</i> , 1884, i, 301.
33	McLeod, K., of Calcutta.	July 28, 1883.	M., 20.	Sarcoma.	Death.	Arm, shoulder, and axilla involved.	<i>Lancet</i> , 1890, i, 847, and personal communication.

34	Verneuil, of Paris.	Nov. 2, 1883.	M., 23.	Sarcoma.	Recovery.	Recurrence and death in a few months.	Tumor of head of humerus invading scapula; size of fetus at term.	* Sambucy: <i>De l'ablation totale du membre supérieur</i> , Paris, 1883.
35	Watson, P. H., of Edinburgh.	Dec. 17, 1883.	M., 50.	Enchondroma.	Recovery.	Patient had had enchondromata of hands for many years. Growth of shoulder began 18 months before operation and was enormous. Scapula and humerus affected.	* <i>Trans. Med. Chir. Soc. Edinb.</i> , 1883-4, iii, 56.
36	Berenger-Feraud, of Lyons.	May 20, 1884.	M., 28.	Necrosis.	Recovery.	* <i>Bull. Arn. de Ther. Med. Chir.</i> , 1885, 490.
37	Lucas-Championnière, of Paris.	June 30, 1884.	M., 38.	Injury.	Recovery.	Died of pneumothorax and phthisis 5 months later.	Machine injury. Arm torn off at upper third; much skin lost above. Amputation on fourth day.	* Trevelot: <i>Quelques consid. sur l'Amph. de l'Omoplate</i> , Paris, 1885.
38	Czerny, J., of Heddelsberg.	July 15, 1884.	M., 41.	Sarcoma.	Recovery.	No recurrence 18 months later.	Sarcoma of axilla had been excised 18 months before.	* <i>Bull. Arch. f. Kl. Chir.</i> , 1888, xxxvii, 141.
39	Ollier, of Lyons.	Oct. 29, 1884.	M., 51.	Sarcoma.	Recovery.	* <i>Lyon Med.</i> , 1885, xviii, 135.
40	Morland, D., of Naples.	March 15, 1885.	F., 51.	Carcinoma.	Death.	Death subsequently; cause not known.	Carcinoma of breast, axilla, and shoulder-joint. Noticed 16 years before. Tumor also resected. Death from shock in 4 hours.	* <i>Il Morgagni Napoli</i> , 1885, xxvii, 565.
41	v. Bergmann, E., of Berlin.	March 23, 1885.	M., 28.	Sarcoma.	Recovery.	Recurred in brain within a year. (Personal communication.)	Tumor noticed several months. Tumor in scapular region and axilla. Skewer control of hemorrhage. Clavicle also removed. Railroad injury.	* <i>Edinburgh Med. Jour.</i> , 1885, August, 168.
42	Bell, J., of Edinburgh.	May 1885.	M., 10.	Sarcoma.	Recovery.	* <i>Med. Press of W. N. Y.</i> , 1885-6, i, 101.
43	Schmidt, E., of Chicago.	July 28, 1885.	M., 7.	Injury.	Recovery.	* <i>Trans. Mich. Med. Soc.</i> , 1886, 218.
44	Hulzinger, T. G., of Zeeland, Mich.	Sept. 19, 1885.	M., 37.	Injury.	Recovery.	* <i>Brit. Med. Jour.</i> , 1886, li, 1161.
45	Mulling, F. A.	Jan. 22, 1886.	M., 50.	Sarcoma.	Recovery.	Recurrence and death. (Chavasse).	Growth noticed 12 months; involved humerus, scapula, and tri-iceps. Tumor 12 inches by 7 inches. (Growth size of man's head; began in humerus and involved scapula and clavicle.)	* <i>Wien. Med. Presse</i> , 1887, xxviii, 650.
46	Odolinski, A., of Krakau.	Feb. 6, 1886.	F., 22.	Sarcoma.	Recovery.	Recurrence in lung and death in 3½ months.	Growth of humerus; scapula and glands involved.	* <i>Braunsfeld, loc. cit.</i>
47	v. Bergmann, E., of Berlin.	July 15, 1886.	M., 41.	Sarcoma.	Recovery.	Recurrence in lung and death in 13 months.	Crush.	* <i>Ann. Anat. et Hist. Nat.</i> , 1887, Nov., 490.
48	Mazzoni, G., of Rome.	July 24, 1886.	M., 18.	Injury.	Death.	No recurrence 3 months later.	Large tumor; began in scapula; noticed about one year.	* <i>Bull. de Soc. Med. di Bologna</i> , 1888, xxi, 66.
49	Poggi, A., of Bologna.	Oct. 13, 1886.	M., 27.	Sarcoma.	Recovery.	No recurrence and in excellent health January 25, 1900. (Personal communication.)	A similar growth with the head of the humerus had been removed 6 years before by Prof. Trendelenberg. Growth followed a blow.	* <i>Grisson: Deutsche Zeit. f. Chir.</i> , 1888, xxvii, 238.
50	Madelung, of Rostock.	Dec. 9, 1886.	M., 48.	Enchondroma.	Recovery.	Recurrence in lung and death soon after.	Forearm amputated 14 months before.	* <i>Braunsfeld, loc. cit.</i>
51	v. Bergmann, E., of Berlin.	Jan. 21, 1887.	M., 20.	Sarcoma.	Recovery.	Recurrence in lung and death in 11 months.	Growth noticed 11 months before. Removed in July, 1886. Recurred in October. Shoulder involved at time of last operation. Operation on the day after injury. Death 2½ hours later.	* <i>Simon: Todd-Estorp. der Scapula</i> , Würzburg, 1894.
52	Reyher, C. C., of St. Petersburg.	Feb. 5, 1887.	M., 53.	Sarcoma.	Recovery.	Recurrence and death in 1 year.	Growth of humerus size of cocoon; tumors in axilla and above clavicle.	* <i>Bull. et Mem. Soc. de Chir.</i> , Paris, 1888, xiv, 484.
53	Jeanot, M., of Toulouse.	May 25, 1887.	M., 26.	Bite of lion.	Death.	Death from acute disease of lung — probably acute sarcomatosis — 21 months later. (Personal communication.)	Central sarcoma of humerus and shoulder.	* <i>Annals of Surgery</i> , 1888, viii, 434.
54	May, R., of Birmingham.	June 1887.	F., 21.	Sarcoma.	Recovery.	Operation one hour after injury.	* <i>Bull. et Mem. Soc. de Chir.</i> , Paris, 1888, xiv, 481.
55	van Herson, J. E., of Leyden.	Aug. 26, 1887.	M., 49.	Sarcoma.	Recovery.	* <i>Gaz. des Hôpitaux</i> , 1887, 1009.
56	Krimson, E., of Paris.	1887.	M., Adlt.	Shot wound.	Death.	Personal communication.
57	Wheelhouse, C. G., of Leeds.	Before 1888.	M., 14.	R. E. injury.	Recovery.	Growth of humerus; spontaneous fracture.	* <i>Braunsfeld; loc. cit.</i>
58	v. Bergmann, E., of Berlin.	Jan. 24, 1888.	F., 34.	Sarcoma.	Recovery.	In good health 15 months later.	Arm caught in belt and torn from body at surgical neck of humerus. Scapula splintered.	* <i>Gaz. des Hôpitaux</i> , 1888, lxi, 331.
59	Boungougon, of Montreuil.	June 25, 1888.	M., 13.	Injury.	Recovery.	No recurrence 9 months later.	Growth of upper end of humerus of large size. Duration, 6 months.	* <i>Wien. med. Woch.</i> , 1889, xxxix, 1121.
60	Sundermayer, R., of Karlsruhe.	March 23, 1888.	F., 41.	Sarcoma.	Recovery.	Recurrence in lungs and death in 15 months. (Personal communication.)	* <i>Annals of Surgery</i> , 1889, viii, 434.
61	May, R., of Birmingham.	April 1888.	M., 17.	Sarcoma.	Recovery.	* <i>Memphis Jour. Med. Sci.</i> , 1889, i, 174.
62	Russell, L. E.	May 13, 1888.	M., 22.	Injury.	Recovery.	Recurrence in thorax and death in 11 months.	Growth of scapula, size of man's head. Patient leukemic. Death next day.	* <i>Keller: Ueber die Ext. der Scap.</i> , Bonn, 1889.
63	Trendelenberg, H., of Bonn.	May 30, 1888.	M., 47.	Sarcoma.	Death.	No recurrence 18 months later.	Tumor of upper half of humerus, size of child's head.	* <i>Nasse: Arch. f. klin. Chir.</i> , xxxix, Heft 4.
64	v. Bergmann, E., of Berlin.	July 24, 1888.	F., 10.	Sarcoma.	Recovery.	Tumor of head of humerus.	* <i>Jour. Am. Med. Assoc.</i> , 1889, xii, 295.
65	Parkes, C. T., of Chicago.	Dec. 10, 1888.	M., 18.	Sarcoma.	Recovery.	Tumor, size of cocoon, grew from shoulder-joint. Exploratory operation 3 weeks before. Death on third day.	* <i>Jour. Am. Med. Assoc.</i> , 1889, xii, 295.
66	Parkes, C. T., of Chicago.	Jan. 11, 1889.	M., 37.	Malignant growth.	Death.	Well in January, 1900. (Personal communication.)	Tumor of 10 years' duration. Growth of upper end of humerus; weighed 18 pounds. Secondary hemorrhage.	* <i>Lancet</i> , 1890, i, 131.
67	Chavasse, T. E., of Birmingham.	Jan. 1889.	M., 40.	Enchondroma.	Recovery.	Recurrence in pleura and lung and death on July 22, 1899. (Personal communication.)	Fracture of humerus 10 years before. Sarcoma of humerus and scapula. Aukylotis.	* <i>Finkelstein: Ein Fall von Ectop. des Schulterg.</i> , Berlin, 1889.
68	Kuster, E., of Berlin.	Feb. 19, 1889.	F., 29.	Sarcoma.	Recovery.	Recurrence internally and death in 2 years. (Personal communication.)	Injury of shoulder 17 months before. Ligation of subclavian artery difficult.	* <i>Annals of Surgery</i> , 1890, xi, 88.
69	Lewis, E. A., of Brooklyn.	April 29, 1889.	M., 47.	Sarcoma.	Recovery.

TABLE I.—TOTAL EXCISION OF THE SCAPULA WITH SIMULTANEOUS REMOVAL OF THE ARM.—CONTINUED.

NO.	OPERATOR	DATE OF OPERATION	SEX AND AGE	CONDITION REQUIRING OPERATION.	RESULT.	SEQUENT HISTORY.	REMARKS.	PLACE OF RECORD.
70	v. Bergmann, E., of Berlin.	July 1889.	F., 36.	Sarcoma.	Death.	Recurrence and death in 5 months. (Chavasse.)	Tumor began in humerus. Resection of first rib and part of sternum and ligation of superior vena cava. Death in 2 hours. Felt on shoulder 3 months before. Growth from subscapular fossa.	* Nassé; loc. cit. * Brit. Med. Jour., 1889, ii, 1334.
71	Southam, F. A., of Manchester.	Aug. 25, 1889.	F., 11.	Sarcoma.	Recovery.	Tramway fracture of humerus, scapula and clavicle. No necrosis.	* Wien. Klin. Woch., 1890, No. 43, 253.
72	v. Eschelsberg, F., of Vienna.	Dec. 1, 1889.	M., 63.	Injury.	Recovery.	Railroad injury.	Personal communication.
73	Park, R., of Buffalo.	1889.	M., 14.	Injury.	Recovery.	Burn of upper arm and shoulder, extending to bone.	* Schultz; Deutsche Ztit. f. Chir., 1896, xliii, 458.
74	v. Bergmann, E., of Berlin.	1889.	Burn.	Recovery.	Death from cystitis 5 months later.	* Costa; Arch. di Ortop., Anno X, 22.
75	Geel, A., of Geneva.	May 28, 1890.	M., 29.	Sarcoma.	Recovery.	No autopsy.	Growth removed from long head of triceps 9 months before. Nodule removed from under chin 3 weeks after operation. Edema of arm. All of clavicle removed.	* N. Y. Med. Jour., 1891, lili, 57.
76	Wythe, J. A., of New York.	Oct. 14, 1890.	M., 51.	Sarcoma.	Recovery.	Recurrence and death within a year. (Personal communication.)	Tumor, size of child's head, appeared 2 years before. Clavicle resected; vessels tied; arm disarticulated; scapula removed.	* Schultz; loc. cit.
77	Helferich, H., of Greifswald.	Oct. 31, 1891.	F., 19.	Sarcoma.	Recovery.	No recurrence in 1899. (Personal communication.)	Sarcoma of humerus yet encapsulated.	* Jago; Ann. Chir. Gynec., Freiburg, 1890.
78	Soup, N., of Chicago.	1890.	M., 35.	Sarcoma.	Recovery.	No known recurrence 6 years later.	Personal communication.
79	v. Bergmann, E., of Berlin.	1890.	M., 29.	Sarcoma.	Recovery.	No recurrence 3½ years later.	Growth of humerus extending into axilla and under scapula.	* Le Mercet; Med., 1891, 43.
80	Monod, E., of Bordeaux.	Feb., 1891.	M., 29.	Sarcoma.	Recovery.	Recurrence in lungs and death in 3 months.	Very large tumor of 3 months' growth. Hemorrhage prevented by elastic cord and skewers.	* Lancet, 1891, ii, 117.
81	McLeod, K., of Calcutta.	Mar. 23, 1891.	F., 15.	Sarcoma.	Recovery.	No recurrence as far as known. (Personal communication.)	Sarcoma of scapula.	* Deutsche med. Woch., 1892, No. 12, 265.
82	Körte, W., of Berlin.	May 31, 1891.	M., 6.	Sarcoma.	Recovery.	Recurrence in lungs, brain, and neck; death in 3 months.	Central sarcoma of upper part of humerus involving shoulder-joint and deltoid.	* Lancet, 1891, ii, 1159.
83	Treves, F., of London.	June 5, 1891.	F., 43.	Sarcoma.	Recovery.	Recurrent carcinoma of breast. Arm largely edematous. Subclavian vein obliterated. Operation done to relieve pain.	* Arch. Prat. de Chir., 1893, ii, 255.
84	Treves, F., of London.	July 3, 1891.	F., 57.	Sarcoma.	Recovery.	Recurrence in lungs and death in 14 months.	Growth began in scapula and extended toward axilla. Voluminous.	* Annals of Surg., 1895, xlii, 736.
85	Poncet, A., of Lyons.	July 21, 1891.	M., 34.	Sarcoma.	Recovery.	Patient since married. In good health in January, 1900. (Personal communication.)	Sarcoma of radius and scapula. Death from shock soon after operation.	* Le Mercet; Med., 1891, 613.
86	Ochsner, A. J., of Chicago.	Aug., 1891.	F., 19.	Sarcoma.	Recovery.	Recurrence and death in January, 1900.	Enormous epithelioma on a surface burned years ago.	Personal communication.
87	Pohallion, of Paris.	Dec. 1, 1891.	M., 46.	Sarcoma.	Death.	Recurrence and death.	Sarcoma of humerus invading the shoulder-muscles.	* Schultz; loc. cit.
88	Park, R., of Buffalo.	1891.	M., 39.	Epithelioma.	Recovery.	Recurrence and death.	Arm muscles and vein filled with growth, which began in humerus.	* Ibid.
89	v. Bergmann, E., of Berlin.	Before 1892.	Sarcoma.	Recovery.	Recurrence and death.	Caused by a blow 2 years before. Sarcoma of upper end of humerus. Soft parts infiltrated.	* Bull. et Mem. Soc. Chir. Par., 1892, xviii, 446.
90	v. Bergmann, E., of Berlin.	Before 1892.	Sarcoma.	Recovery.	Recurrence and death.	Large growth over scapula and filling axilla. First noticed 5 weeks before. No preceding trauma.	* Lancet, 1892, ii, 471.
91	Delorme, of Paris.	March, 1892.	M., 20.	Sarcoma.	Recovery.	Well in April, 1897; not seen since. (Personal communication.)	Tumor noticed in March, 1890. Growth from humerus and scapula, 30 inches around. Result of injury 4 years before.	* Maritime Med. News, 1894, vi, 391.
92	Chavasse, T. F., of Birmingham.	May 20, 1892.	M., 21.	Sarcoma.	Recovery.	Recurrence in lung and death in 2 years. (Personal communication.)	Progressive plegnum of arm; edema of thorax. Subclavian vessels tied; arm disarticulated; scapula removed. Death same day.	* Frank; Ueber die Abgrenzung der Oberen Extremität der Scap., Greifswald, 1895.
93	Sheldrake, F. J., of Montreal.	June 17, 1892.	F., 32.	Chondrosarcoma.	Recovery.	Patient has since died; cause unknown.	Sarcoma of upper end of humerus. Cystic degeneration. Spontaneous fracture.	* Schultz; loc. cit.
94	Helferich, H., of Greifswald.	Dec. 30, 1892.	M., 47.	Progressive plegia.	Death.	No recurrence one year later.	Sarcoma of upper end of humerus.	* Ibid.
95	v. Bergmann, E., of Berlin.	1892.	Sarcoma.	Recovery.	Necrosis of humerus and scapula. Suppuration of elbow and shoulder-joints.	* Ibid.
96	v. Bergmann, E., of Berlin.	1892.	Sarcoma.	Recovery.	Tumor of scapula. Five operations made between 1884 and 1892.	* Inter. Klin. Rundschau, 1893, vii, 417.
97	v. Bergmann, E., of Berlin.	1892.	Necrosis.	Recovery.	* Deutsche med. Woch., 1893, xix, 1187.
98	Frank, R., of Vienna.	Feb. 1, 1893.	M., 45.	Enchondroma.	Recovery.	No recurrence 6 years later. (Personal communication.)	* Medical Sentinel, 1895, iii, 386.
99	Künnell, H., of Hamburg.	Mar. 13, 1893.	M., 47.	Sarcoma.	Recovery.	* Bull. Soc. Anat. Clin. Lille, 1893, xlii, 140.
100	MacKenzie, K. A. J., of Portland.	Aug., 1893.	M., 63.	Carcinoma.	Recovery.	* Am. Jour. Med. Sci., 1894, cxvii, 680.
101	Guernimprez, of Lille.	Oct. 21, 1893.	M., 46.	Sarcoma.	Recovery.	Patient perfectly well in January, 1900. (Personal communication.)	Sarcoma of head of humerus, involving joint. Edema of arm. Humerus involved upper arm, shoulder joint, and scapula. Great trouble in securing subclavian vein.	* Centralbl. f. Chir., 1895, 956.
102	Keen, W. W., of Philadelphia.	Nov. 20, 1893.	F., 29.	Sarcoma.	Recovery.	Patient perfectly well and without sign of recurrence on April 4, 1900. (Personal communication.)	Tumor previously excised. Sarcoma of upper end of humerus.
103	Roth, of Lubbeck.	Nov., 1893.	M., 15.	Sarcoma.	Recovery.	Recurrence on April 4, 1900. (Personal communication.)	Growth of humerus. Muscles not yet invaded. Noticed only a month.	* Schultz; loc. cit.
104	v. Bergmann, E., of Berlin.	1893.	Malignant growth.	Recovery.	Recurrence growth excised from shoulder the next year.

105	Ochsner, A. J., of Chicago.	June 1, 1894.	Chondrosarcoma.	Recovery.	No recurrence in January, 1900. (Personal communication.)	Growth in suprascapular, serratus magnus and over clavicle. Tumor of 4 months' growth. Large growth of the scapula; appeared 8 months before.	* <i>Annals of Surgery</i> , 1895, xxii, 736. Personal communication.
106	Patterson, A., of Glasgow.	June 14, 1894.	Sarcoma.	Recovery.	Recurrence in lungs and death in 10 months.	Growth of upper part of humerus and scapula.	* <i>Bull. Med. du Nord</i> , 1895, xxxiv, 1.
107	Tubat, L., of Lille.	July 11, 1894.	Sarcoma.	Recovery.	Recurrence. Small secondarily growth removed. Relief considered only temporary.	Began after a contusion 5 years before. Large growth of scapula and neck. Flap from upper arm. Growth followed fracture of clavicle. Clavicle also removed. Toxins had been previously tried.	* <i>Traus. London Clin. Soc.</i> , 1895, xxviii, 655.
108	Spencer, G. W., of London.	Sept. 14, 1894.	Lymphosarcoma.	Recovery.	No recurrence 6 months later.	Fracture 2 years before in scapula. Tumor appeared 2 months before operation and involved humerus and neck of scapula.	* <i>Kansas City Med. Index</i> , 1895, xvi, 105.
109	Kend, W. W., of Philadelphia.	Dec. 26, 1894.	Sarcoma.	Recovery.	Died 15 months later of recurrence in cheek. (Personal communication.)	Excision of growth with upper two-thirds of humerus 3 months before.	* <i>Montreal Med. Jour.</i> , 1896, xxiv, 655.
110	Arnsperg, G. F., of Montreal.	Jan. 12, 1895.	Sarcoma.	Recovery.	In January, 1900, she had pulmonary tuberculosis. No recurrence. (Personal communication.)	Tumor of scapula involving shoulder-joint.	* <i>Gaz. Med. de Strasbourg</i> , 1896, xxv, 73.
111	Boeckel, J., of Strasbourg.	March 20, 1895.	Sarcoma.	Recovery.	Recurrence in <i>larynx</i> and in lungs and death 5 months later.	Arm torn off below elbow. Operation within an hour of accident.	* <i>Arch. Med. de Toulouse</i> , 1897, iii, 145.
112	Jeanand, M., of Toulouse.	March 30, 1895.	Sarcoma.	Recovery.	Recurrence in lungs and death in 5 or 6 months. (Personal communication.)	Sarcoma of humerus, overlapping acromion and clavicle.	* <i>Annals of Surgery</i> , 1896, xxiv, 182.
113	Clayson, V. F., of Birmingham.	May 7, 1895.	Injury.	Recovery.	Perfectly well in January, 1900, doing field work on a farm. (Personal communication.)	Fluctuating tumor of humerus, size of child's head. Edema of arm. Spontaneous fracture of humerus. Fracture of humerus in January, 1895.	* <i>Arch. Prov. de Chir.</i> , 1896, v, 13.
114	Honzel, G., of Besancon.	July 25, 1895.	Sarcoma.	Recovery.	Sarcoma of upper end of humerus.	* <i>Berliner Klin. Woch.</i> , 1895, 1014.
115	Birkesen, of Berlin.	Aug. 23, 1895.	Myxosarcoma.	Recovery.	Patient remained free from recurrence and died of influenza pneumonia, February, 1899. (Personal communication.)	* <i>Centralbl. f. Chir.</i> , 1895, 966.
116	Roth, of Lübeck.	Aug. 27, 1895.	Sarcoma.	Recovery.	No recurrence 14 months later.	* <i>St. Petersburg Med. Woch.</i> , 1897, xiv, 215.
117	Wannach, K., of St. Petersburg.	Sept. 27, 1895.	Sarcoma.	Recovery.	Angioma of shoulder of 10 years' standing. Trauma one year before operation. Sarcoma of scapula size of child's head.	* <i>Rivista Venet. di Sci. Med.</i> , 1896, xxiv, 211.
118	Cavazzani, G., of Padua.	Oct. 3, 1895.	Sarcoma.	Recovery.	Tumor of pectoral region removed September, 1890. Fourteen recurrences operated in 5 years.	* <i>Schultz: loc. cit.</i>
119	von Bergmann, E., of Berlin.	Nov. 1895.	Sarcoma.	Recovery.	Sarcoma of upper end of humerus.	* <i>Annals of Surgery</i> , 1900, xxxi, 211.
120	Fowler, G. R., of Brooklyn.	Dec. 7, 1895.	Burn.	Death.	Deep laceration of arm and forearm 3 weeks before. Death on fourth day from pneumonia.	Personal communication.
121	Sohn, S., of Chicago.	Tuberculosis.	Death.	Shoulder joint previously resected.	Personal communication.
122	Sohn, S., of Chicago.	Sarcoma.	Death.	* <i>P. & S. Heres</i> , Chicago, 1895, 1, 19.
123	Steele, D. A. K., of Chicago.	Sarcoma.	Recovery.	Recurrence in scar and neck. Excision 5 weeks after primary operation.	Tumor began in scapula 7 weeks before and extended into axilla.
124	Hall, G. C., of Allahabad.	Before 1896.	Tumor.	Recovery.	Tumor originated in humerus and weighed 34 pounds. Dissection from behind.	* <i>Indian Med. Record</i> , 1896, x, 10.
125	Sapiezko, K. M., of Kiew.	Jan. 1896.	Curdnomia.	Recovery.	Recurrence after excision of breast and axillary glands.	* <i>Wannach, St. Petersburg Med. Woch.</i> , xiv, 216.
126	Cabot, A. T., of Boston.	Feb. 1896.	Sarcoma.	Recovery.	Metastasis and death in about 6 months.	Growth of scapula size of coconut; followed a blow.	* <i>Boston M. & S. Jour.</i> , 1896, cxxxv, 411.
127	Keen, W. W., of Philadelphia.	March 19, 1896.	Sarcoma.	Death.	Death from anemia 4 days later.	Personal communication.
128	Chambers, H. C., of Glasgow.	March 1896.	Sarcoma.	Recovery.	Neuroma afterwards formed in stump of brachial plexus. Growth noticed 13 months.	* <i>Traus. Glasgow Path. & Clin. Soc.</i> , 1897, vi, 55.
129	Graves, S. C., of Grand Rapids.	April 10, 1896.	Tuberculosis.	Recovery.	Excision of head of humerus, August 22, 1895.	* <i>Trans. Mich. Med. Soc.</i> , 1897, 421.
130	Klintonson, E., of Paris.	April 27, 1896.	Sarcoma.	Recovery.	Recurrence in lungs and death in 7 months.	Very large sarcoma of upper end of humerus.	* <i>Rev. de Chir.</i> , 1898, xviii, 861.
131	Magnusson, G., of Reykjavik.	April 29, 1896.	Tuberculosis.	Recovery.	Hosp. Tid. Kjöbenhavn, 1897, 4 R, v, 598.
132	Edel, E. F., of Southampton.	May 31, 1896.	Myxosarcoma.	Recovery.	Four operations for local recurrence and death in 2 years. (Personal communication.)	Disease began over 4 years before in region of scapula. Excision practised 12 times.	* <i>Lancet</i> , 1896, ii, 1394.
133	Stonham, C., of London.	June 2, 1896.	Chondrosarcoma.	Recovery.	Died in March, 1898, with symptoms of intestinal recurrence. (Personal communication from Mr. E. Percy Paton.)	Growth of scapula, noticed for one year. Tumor about the size of a nut.	* <i>Westminster Hosp. Rep.</i> , London, 1897, x, 136.
134	Poussat, A., of Buenos Ayres.	June 12, 1896.	Sarcoma.	Recovery.	No recurrence 7 months later.	Tumor of humerus larger around than child's thorax. Growth noticed 6 months.	* <i>Rev. de Chir.</i> , 1897, xvii, 865.
135	Bishop, W., of New York.	Aug. 6, 1896.	Necrosis.	Recovery.	Necrosis the result of injury 18 months before.	* <i>Haberman. Monthly</i> , 1897, xxii, 43.
136	Lenger, of Liège.	Aug. 26, 1896.	Sarcoma.	Recovery.	Recurrence in <i>larynx</i> and in other shoulder and death in 11 months. (Personal communication.)	Sarcoma of humerus.	* <i>Annals Soc. Belge de Chir.</i> , 1899, vii, 125.
137	Lloyd J., of Birmingham.	August, 1896.	Edema of arm.	Death.	Solid edema of whole limb following excision of breast for cancer. Enlarged glands above clavicle. Death on third day.	Personal communication.

TABLE I.—TOTAL EXCISION OF THE SCAPULA WITH SIMULTANEOUS REMOVAL OF THE ARM.—CONTINUED.

NO.	OPERATOR.	DATE OF OPERATION.	SEX AND AGE.	CONDITION REQUIRING OPERATION.	RESULT.	SUBSEQUENT HISTORY.	REMARKS.	PLACE OF RECORD.
138	Kolbker T., of Leipzig.	Oct. 1-26, 1896.	M., 50.	Sarcoma.	Recovery.	Recurrence in brain and death in about 2 years. (<i>March, Med. Woch., No. 2, 1903.</i>)	Tumor of scapula, size of child's head.	* <i>March, med. Woch., 1897, xlv, 536.</i>
139	Bowker, R. S., of Sydney.	Nov. 1896.	M., 16.	Sarcoma.	Recovery.	Recurrence in lung and death in 16 months. (Personal communication.)	Upper arm and shoulder involved. History of repeated blows. Growth noticed 4 months.	* <i>Los Angeles, Med. Jour., 1897, xvi, 13.</i>
140	Schwartz.	1896.	F., 20.	Chondrosarcoma.	Recovery.	Known to remain well for many months.	Enormous growth of upper end of humerus of 9 years' duration.	<i>Bull. et Mem. Soc. Chir., Par., 1896, xlv, 830.</i>
141	Marsh, F., of Birmingham.	Feb. 1897.	F., 10.	Sarcoma.	Recovery.	Recurrence in lung and death in 7 months.	No previous injury. Growth began in head of humerus; pathological fracture 3½ years before. Enlargement began 2½ years before in upper arm and tumor had become enormous.	<i>Birmingham Med. Rev., April, 1897, 37.</i>
142	Baring, G., of Birmingham.	Feb. 1897.	M., 53.	Sarcoma.	Recovery.	Multiple recurrences. Six months later, patient evidently had but a short time to live.		* <i>Trans. Lanc. Clin. Soc., 1898, xxxi.</i>
143	Baring G., of Birmingham.	Feb. 1897.	M., 37.	Sarcoma.	Recovery.	No recurrence in January, 1900, and in robust health. (Personal communication.)	Pain in upper arm for 6 months; swelling for 2 months. Periosteal growth of humerus and shoulder joint.	* <i>Ibid.</i>
144	Bryer J., of Paris.	Mar. 1897.	M., 28.	Myxochondroma.	Recovery.	No recurrence January 21, 1900. (Personal communication.)	Growth began in medulla of humerus. Enlargement noticed 2½ months. No traumatism. Tumor size of turkey egg.	* <i>La Bull. M-d., Paris, 1897, xl, 549.</i>
145	Quenu, of Paris.	Mar. 1897.	M., 6.	Sarcoma.	Recovery.	Death 4 months later. (Beyger.)	Sarcoma of humerus. Axillary glands enlarged.	* <i>Bull. Soc. Anat. Par., 1897, lxi, 287.</i>
146	Drenl Pachay, of Constantinople.	Mar. 1897.	M., 40.	Sarcoma.	Recovery.	Recurrence in lungs and death in 2 months.	Tumor of upper third of humerus.	* <i>Gaz. Med. d'Orient, 1898, xlii, 319.</i>
147	Hackel, of Stettin.	April 30, 1897.	F., 28.	Sarcoma.	Recovery.	No recurrence 20 months later.	Pain and swelling of shoulder began in August, 1896. Spontaneous fracture in February, 1897. Upper part of humerus destroyed by growth.	* <i>Könitzer: Deutsche Zeit. f. Chir., 1899, 594.</i>
148	Hahn, F., of Berlin.	May 1897.	M., 20.	Sarcoma.	Recovery.		Growth removed from upper end of humerus March 7. Scapula and soft part now involved.	* <i>Deutsch. med. Woch., 1898, xxiv, 100.</i>
149	Hackel, of Stettin.	July 1897.	M., 41.	Tuberculosis.	Recovery.		Shoulder-joint, chest wall, and flexor tendons of forearm affected. Conservative operation done one week before.	* <i>Könitzer: loc. cit.</i>
150	Drenl Pachay, of Constantinople.	Sept. 1897.	M., 50.	Sarcoma.	Recovery.	No recurrence 3 months later.	Tumor in deltoid region size of adult head.	* <i>Gaz. Med. d'Orient, 1898, xlii, 319.</i>
151	Pent, F., of London.	Oct. 1897.	F., 56.	Carcinoma.	Recovery.	Secondary visceral growths in 5 months.	Recurrent carcinoma of axilla. Breast removed 3 years before. Arm swollen; pain severe.	<i>Brit. Med. Jour., 1898, i, 690.</i>
152	Hackel, of Stettin.	Nov. 1897.	F., 63.	Sarcoma.	Death.		Pain and swelling of shoulder for 3 months. Tumor began in scapula and perforated shoulder joint. Autopsy showed involvement of liver. Death in 3 hours.	* <i>Könitzer: loc. cit.</i>
153	Reebot, V., of Lyons.	Dec. 1897.	M., 28.	Sarcoma.	Recovery.		Sarcoma of humerus.	<i>La Proc. Med., 1898, xlii, 77.</i>
154	Dejardin, F., of Liege.	Jan. 1898.	M., 16.	Injury.	Recovery.		Arm almost torn off by railroad accident. Clavicle and scapula fractured.	<i>Annals Soc. Belge de Chir., 1898, vi, 65.</i>
155	Porter C. R., of Boston.	Jan. 1898.	M., Ad'l.	Malignant growth.	Recovery.		Disease began in thumb 19 years before. Forearm previously amputated. Pectoral muscles also removed.	* <i>Boston Med. and Surg. Jour., 1898, cxxxix, 389.</i>
156	Boyd, S., of London.	Mar. 1898.	M., 26.	Malignant growth.	Recovery.	Recurrence in liver and death in 2½ months.	Growth in axilla and scapular muscles. Duration 3 months. Exploratory operation February 21.	Personal communication.
157	Robson, A. W. M., of Leeds.	Mar. 1898.	M., 31.	Tuberculosis.	Recovery.		Tuberculosis of body of scapula, shoulder and elbow; osteomyelitis of humerus. Frequently operated on during 3 years before.	<i>Lancet, 1899, i, 273.</i>
158	Chavasse, T. F., of Birmingham.	March 1898.	M., 19.	Painful stump.	Recovery.		In 1896, arm amputated at upper third for railway crash, which fractured clavicle and scapula, and caused sloughing of axillary soft parts. Result, a painful exanthematous stump, bound down to chest.	Personal communication.
159	Leenger, of Liege.	March 1898.	M., 33.	Sarcoma.	Recovery.	Recurrence <i>in loco</i> and death in 11 months.	Sarcoma of head of humerus.	<i>Ann. Soc. Belge de Chir., 1899, vii, 125.</i>
160	Dallinger, G., of Baden.	May 1898.	M., 17.	Sarcoma.	Recovery.	Secondary operations at scar in September and January following.	Medullary growth of scapula.	Orvost helthp. szem., 1899, xxvi, 274.
161	Keen, W. W., of Philadelphia.	May 1898.	F., 15.	Sarcoma.	Recovery.	Recurrence and death in 10 months.		Personal communication.
162	Robson, A. W. M., of Leeds.	June 1898.	M., 38.	Sarcoma.	Recovery.	Death, February 18, 1899, from some other cause quite independent of the disease for which operation had been done. (Personal communication.)	Growth began on hand in 1895. Extised from hand three times and from axilla once. Present growth involved axillary vessels and neck of scapula.	<i>Lancet, 1899, i, 273.</i>
163	Keen, W. W., of Philadelphia.	July 1898.	M., 33.	Sarcoma.	Recovery.	Fourteen months later was thought to have an internal recurrence.		Personal communication.
164	Eastler, R. S., of Brooklyn.	July 1898.	F., 52.	Sarcoma.	Recovery.	No recurrence more than one year later.	No history of injury. Tumor began 18 months before, above elbow. Growth previously excised. Ticeps involved.	* <i>Annals of Surgery, 1900, xxxi, 54.</i>
165	Jennel, M., of Toulouse.	Oct. 1898.	M., 30.	Sarcoma.	Recovery.	Recurrence in 2 months.	Growth began in humerus 1 year before.	<i>Archiv. Med. Par., 1899, 115.</i>
166	Hackel, of Stettin.	Oct. 1898.	M., 50.	Sarcoma.	Recovery.	Recurrence in scar and in lung, and death in 5 months.	Tumor of deltoid axilla and breast; bones not involved.	<i>Könitzer: loc. cit.</i>
167	Sonnenberg, of Berlin.	Oct. 1898.		Sarcoma.	Recovery.		Growth of humerus	<i>Centralbl. f. Chir., 1899, No. 9.</i>

168	Hackel, of Steflin.	Jan. 6, 1899.	F., 12.	Sarcoma.	Recovery.	No recurrence in chest and death in 8 months.	Injury to upper arm by being thrown down 6 weeks before. Tumor of upper arm, size of child's head.	* K��nigler: <i>loc. cit.</i>
169	K��lliker, F., of Leipzig.	Feb. 1899.	F., 56.	Sarcoma.	Recovery.	No recurrence 6 months later.	Tumor noticed 1 month; size of apple; grew from spine of scapula in suprascapular fossa, involving joint of shoulder. Axillary glands involved.	* <i>M��nch. med. Woch.</i> , No. 2, 1900.
170	La Conte, R. G., of Philadelphia.	April 12, 1899.	M., 49.	Malignant growth.	Recovery.		Small growth appeared on shoulder 2½ years before. Growth with accumulation and part of clavicle removed about 2 years before. Tumor large and fungoid. Entire clavicle removed.	* <i>Annals of Surg.</i> , 1899, xxx, 260.
171	Fowler, G. R., of Brooklyn.	June 19, 1899.	M., 75.	Carcinoma.	Death.		No history of injury. Pain in elbow and shoulder for 1 year. Swelling for 3 months. Excision of growth 6 days before operation.	* <i>Annals of Surg.</i> , 1900, xxxi, 57.
172	Buchanan, J. J., of Pittsburgh.	Aug. 7, 1899.	M., 62.	Sarcoma.	Recovery.	No recurrence in April, 1900.	Tumor originated in upper arm. Four previous operations for excision of growth.	In body of present paper.
173	Buchanan, J. J., of Pittsburgh.	Sept. 19, 1899.	M., 42.	Sarcoma.	Recovery.	Recurrence in lungs and death in 5 months.	Growth noticed about 3 years before in upper arm. Seven operations for excision.	<i>Ibid.</i>
174	Vercall, T. J.	F., 39.	Sarcoma.	Recovery.	No recurrence 10 months later.	Growth noticed 5 months. Humerus and scapula involved.	<i>Lancet</i> , February 12, 1900.
175	Handlman, W. D., of Columbus.	Nov. 15, 1899.	M., 32.	Sarcoma.	Recovery.		Three injuries to shoulder in previous year. Head of humerus, glenoid process, and scapular muscles involved. Entire clavicle removed by chisel.	* PHILADELPHIA MEDICAL JOURNAL, 1900, v, 464.
176	Cushing, H., of Baltimore.	Dec. 26, 1899.	F., 41.	Sarcoma.	Recovery.		Large growth involving vessels and nerves of axilla. Pectoral muscles also removed.	Personal communication.
177	Ziegler.	1899.	Gangrene of arm.	Recovery.		Laceration of axillary artery.	<i>Deutsche med. Woch.</i> , 1899, March 16.
178	Cushing, H., of Baltimore.	Jan. 2, 1900.	M., 32.	Sarcoma.	Recovery.		Large growth of upper end of humerus, involving head of scapula. Pathological fracture.	Personal communication.
179	van Herson, J. E., of Leyden.	Jan. 29, 1900.	M., 46.	Sarcoma.	Recovery.		Sarcoma of humerus, infiltrating soft parts of shoulder.	Personal communication.
180	Fowler, G. R., of Brooklyn.	Jan., 1900.	Progressive phlegmon.	Death.		Extensive streptococcus infection of entire arm and shoulder region with septopyemia.	Personal communication.
181	Fowler, G. R., of Brooklyn.	March 2, 1900.	M., 42.	Sarcoma.	Recovery.			<i>Ibid.</i>

Dr. Buchanan's Case I. (6th day.)

SUMMARY OF TABLE I.

INTERSCAPULOTHORACIC AMPUTATIONS.

For malignant growths	131
For semi-malignant and doubtful growths	10
For injury	24
For necrosis	4
For tuberculosis	5
For burn	2
For phlegmonous inflammation	2
For cicatricial stump	1
For edema of arm	1
For gangrene of arm	1

Total..... 181

Malignant growths: 2, 3, 4, 11, 12, 13, 14, 15, 20, 22, 23, 26, 27, 28, 29, 30, 32, 33, 34, 38, 39, 40, 41, 42, 45, 46, 47, 49, 51, 52, 54, 55, 58, 60, 61, 63, 64, 65, 66, 68, 69, 70, 71, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 95, 96, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 114, 115, 116, 117, 118, 119, 122, 123, 125, 126, 127, 128, 130, 132, 133, 134, 136, 138, 139, 141, 142, 143, 145, 146, 147, 148, 150, 151, 152, 153, 155, 156, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 178, 179, 181.

Semi malignant and doubtful growths: 17, 19, 31, 35, 50, 67, 98, 124, 140, 144.

Injury: 1, 5, 6, 7, 8, 9, 10, 16, 18, 21, 24, 37, 43, 44, 48, 53, 56, 57, 59, 62, 72, 73, 113, 154.

Necrosis: 25, 36, 97, 135.

Tuberculosis: 121, 129, 131, 149, 157.

Burn: 74, 120.

Phlegmonous inflammation: 94, 180.

Cicatricial stump: 158.

Edema of arm: 137.

Gangrene of arm: 177.

SEX OF PATIENTS AMPUTATED FOR NEOPLASM.

Males	92
Females	38
Not stated	11

Total..... 141

CLASSIFICATION OF GROWTHS.

Sarcoma	112
Carcinoma	7
"Malignant growths"	12
Enchondroma	8
Not stated	2

Total..... 141

OPERATIVE MORTALITY.

For all cases, 29 deaths in 181 operations	16%
For neoplasm, 17 deaths in 141 operations	12%
For neoplasm, before antiseptics (1881-2) 7 deaths in 17 operations	41%
For neoplasm, since antiseptics (1881-2) 10 deaths in 124 operations	8%
For injury, 7 deaths in 24 operations	29%
For necrosis, 4 cases	No mortality.
For tuberculosis, 1 death in 5 operations	20%
For burn, 1 death in 2 operations	50%
For phlegmon, 2 fatal cases	100%
For cicatricial stump, 1 case	No mortality.
For edema of arm, 1 fatal case	100%
For gangrene of arm, 1 case	No mortality.

REMOTE RESULTS OF INTERSCAPULOTHORACIC AMPUTATION
FOR NEOPLASM.*Malignant Growths.*

Death from operation	16
Undetermined cases operated less than 3 years ago	16
Cases without record beyond 3 years	24
Death from intercurrent or unknown causes	5
Later recurrence, but final result not reported	8
Death from recurrence	49
Free from recurrence for 3 years or more	13

Total..... 131

Of these 70 cases (8+49+13), in which the remote result is known, 13 remained free from recurrence for 3 years or more, i. e., 18.6% cured beyond the 3-year limit.

MALIGNANT GROWTHS.

Died from operation: 14, 15, 22, 26, 28, 29, 33, 40, 63, 66, 70, 87, 122, 127, 152, 171.

Undetermined cases operated less than 3 years ago: 147, 148, 150, 153, 155, 161, 167, 169, 170, 172, 174, 175, 176, 178, 179, 181.

Cases without record beyond 3 years: 11, 13, 23, 39, 49, 58, 60, 65, 78, 81, 83, 84, 91, 96, 99, 101, 108, 115, 117, 118, 119, 121, 128, 134.

Died from intercurrent or unknown causes: 38, 41, 75, 95, 162.

Later recurrence, but final result not reported: 104, 107, 123, 142, 151, 160, 163, 165.

Died from recurrence: 2, 3, 4, 20, 27, 30, 32, 34, 42, 45, 46, 47, 51, 52, 54, 55, 61, 64, 68, 69, 71, 76, 80, 82, 85, 88, 89, 90, 93, 100, 109, 111, 112, 126, 130, 132, 133, 136, 138, 139, 141, 145, 146, 156, 159, 161, 166, 168, 173.

Free from recurrence for 3 years or more: 12, 77, 79, 86, 92, 100, 102, 103, 105, 110, 114, 116, 143.

ENCHONDROMATA.

Death from operation	1
Cases without record beyond 3 years	3
Free from recurrence for 3 years or more	4

Of these 4 cases in which the subsequent history is known, all were cured beyond the 3-year limit.

Enchondromata: 17, 31, 35, 50, 67, 98, 140, 144.

INTERSCAPULOTHORACIC AMPUTATIONS FOR MORBID GROWTH,
IN WHICH IT WOULD APPEAR TO HAVE BEEN POSSIBLE TO
EXTERMINATE ALL THE TISSUES EVIDENTLY DISEASED BY DIS-
ARTICULATING AT THE SHOULDER-JOINT:

27, 31, 41, 58, 60, 61, 64, 67, 79, 84, 91, 95, 96, 103, 104, 115, 116, 119, 130, 134, 135, 140, 144, 145, 146, 147, 153, 159, 161, 165, 167, 168, 172, 173. All of these 34 cases recovered.

Cases of enchondroma free from recurrence for 3 years or more	3
Cases of enchondroma without record beyond 3 years	1
Cases of sarcoma without record beyond 3 years	13
Cases of sarcoma dead later from unknown causes	2
Cases of sarcoma with later recurrence, but final result not reported	2
Cases of sarcoma dead from recurrence	10
Cases of sarcoma free from recurrence for 3 years or more	3

34

Of the 15 cases of sarcoma (2+10+3) in which the remote result is known, 3 remained free from recurrence for 3 years or more, i. e., 20% cured beyond the 3-year limit.

Dr. Buchanan's Case II. Taken on seventh day after operation.

SUMMARY OF CASES IN TABLE II.

Malignant growth	23
Enchondroma	4
Infective bone-diseases	4
	31

Immediate mortality: 4 cases in 31, or 13%.

Immediate mortality in cases of neoplasm: 4 cases in 27, or 15%.

REMOTE RESULTS IN CASES OF NEOPLASM.

Malignant Cases.

Died from operation	3
Died from pneumonia (?) in several weeks	1
No record beyond one year	3
Died from recurrence	15
Died from typhus 6 years later	1
	23

Of these 16 cases, recovered from operation and with known history, one was known to remain free from recurrence beyond 3 years, i. e., 6.25% of ultimate cures.

Enchondroma.

Of 4 cases of enchondroma, one patient died after operation, one died from recurrence and two remained cured beyond 3 years.

* This is the case of Bosch, of Bonn, operated in 1861. Owing to my inability to consult the original report of this case, I am uncertain whether this was a case of sarcoma, verified by microscopic examination, or merely a "fleshy tumor," to all which at that time the name "sarcoma" was applied by many writers.

TABLE II.—TOTAL EXCISION OF THE SCAPULA SUBSEQUENT TO DISARTICULATION AT THE SHOULDER JOINT.

NO.	OPERATOR.	DATE OF OPERATION.	AGE AND SEX.	CONDITION REQUIRING OPERATION.	RESULT.	SEQUENT HISTORY.	REMARKS.	PLACE OF RECORD.
1	Mussey, R. D., of Hannover, N. H.	Sept. 28, 1837.	M., 46.	Enchondroma.	Recovery.	No recurrence 30 years later.	Amputation of part of hand 19 years before. Disarticulation at shoulder 6 years before. Claylike tumor removed.	* <i>Am. Jour. Med. Sci.</i> , 1837-8, xxi, 330.
2	Regaud, of Strasbourg.	May 1843.	M., 51.	Osteochondroma.	Recovery.	No recurrence 3 years later.	Disarticulation at shoulder 8 months before.	* <i>Extrép. du Supp. en Tur.</i> , Strasb., 1850.
3	Ferguson, W., of Edinburgh.	Feb. 6, 1847.	M., 32.	Carcin.	Recovery.	Disarticulation at shoulder 7 years before.	* <i>Med. Times</i> , London, 1846-7, xv, 202.
4	Sampart, F., of Ghent.	April 21, 1857.	M., 40.	Fibrosarcoma.	Recovery.	Recurrence and death in 82 days.	Acromion, glenoid, and lower border had been removed with the arm.	* <i>Ann. Soc. de Med. de Gand</i> , 1858, xxxvi, 57.

A CASE OF PRIMARY ADENOCARCINOMA OF THE GALLBLADDER WITH SECONDARIES IN BOTH ADRENALS, MELANOSIS OF SKIN (ADDISON'S DISEASE?), VITILIGO, AND HYPERTROPHY OF THE PANCREAS.

BY ALFRED SCOTT WARTHIN, M.D., Ph.D.,
of Ann Arbor, Mich.

Assistant Professor in Pathology, University of Michigan.

THE report of this case of primary adenocarcinoma of the gallbladder is of interest, not only because of the relative rarity of this condition, but also for the unusual combination of other pathologic changes which it presents. One of these, vitiligo, is a disease which has been studied histologically but rarely, while hypertrophy of the pancreas is a condition almost unknown in the literature of the pathology of this organ.

History of the Case.—Mr. J. P. B., aged 45, was admitted to the University Hospital on October 6, 1899. At the time of admission he exhibited marked jaundice, and was on this account assigned to Dr. Dock's clinic.

His family history was negative. He was unmarried and an ice dealer by occupation. No history of previous illness was given. He had been a hard drinker, but denied venereal disease.

The present illness was stated to have begun 15 weeks before the time of admission. He had first noticed that his skin was becoming yellow, and very soon after this he began to have pains under his left shoulder-blade. The yellow color of his skin gradually deepened. Two weeks after the appearance of the first symptoms the backs of his hands began to turn brown, appearing as if deeply tanned; the brownish pigmentation extended to the finger-tips. At the same time a brownish coloration appeared over face and neck. Later, white patches began to appear over the fingers and backs of hands. These patches became paler, while the surrounding pigmented skin appeared to grow darker.

There was constipation from the beginning; the stools at first were normal in color, but gradually became pale clay-colored. The urine was dark from the first. His appetite had been poor throughout; he had vomited but twice during the entire course of his illness. He had lost about 50 pounds in weight. There had been no pain in the liver region, but that which was felt under the left shoulder had at times extended to the right side. No history of colic or of the passing of gallstones could be obtained. Two weeks before admission he had been delirious at times.

The physical examination made on the day after entrance is condensed as follows: The patient appears very ill, apathetic; lies in passive dorsal position; sleeps with mouth open. His mind is very dull, and speech thick. (Has been taking codéin.)

Height, 5 feet 7 inches; fairly well built. Musculature medium; muscles soft and flabby. There is very small amount of panniculus. The skin is dry and inelastic. It is of a dark saffron color over the trunk and upper portions of the extremities. The hands and wrists are dark brown with irregular patches of leukoderma over the fingers and backs of hands. The lower portion of the face is a very dark brown with yellowish tinge. Over the abdomen are irregular brownish-green patches (blister-scars). The sclerae are very dark yellow. The tongue is dry and cracked, and the gums are swollen. Ankles are puffed, but pit very slightly on pressure.

The liver-dulness begins in the fourth intercostal space in the right parasternal line, and is at the same height in the nipple and axillary lines. It extends to the left to within half an inch of the left nipple line. Traube's space is tympanitic. In the right nipple line the lower border of liver-dulness is 3½ inches below the edge of the ribs; in the right parasternal line 2½ inches below; and in the middle line it reaches just to the tip of the ensiform. The liver cannot be felt.

The splenic dulness is not enlarged. The spleen is not palpable.

The abdomen is distended about ½ inch above the level of the ribs. In the horizontal position there is dulness as high up as the parasternal lines, where a tympanitic sound is obtained. There is no fluctuation.

The examination of heart is negative. The pulse is 88, small, of low tension, and regular.

Otherwise the physical examination is negative.

Urine.—(24 hours), 500 cc., dark brown in color with yellow foam; specific gravity, 1.014. All tests for albumin negative. Good bile-pigment reaction with nitric acid. Moderate test for indican. Acetone test negative. The diazo test gave a reddish ring, brown liquid, and dirty foam. No reduction of Fehling's. The sediment contained an excess of leukocytes and a few cylindroids.

Blood.—Is of a dark color, flows slowly. The red blood-cells are 4,800,000, leukocytes 10,200, hemoglobin 85%.

Sputum.—Small amount of thin watery brownish sputum. Negative.

Stools.—Small in amount, not formed, colorless, and foul.

The weakness and apathy of the patient rapidly increased during the first few days after admission. He had occasional attacks of delirium and in one of these wandered from his bed. Albumin and bile-stained casts appeared in his urine on the third day after entrance and increased constantly in amount and numbers until the day of death. The physical signs remained about the same; the jaundice did not change. The abdomen became more distended. No tumor was ever felt. The edema of lower extremities gradually increased. The temperature ranged from normal to 100°, 2 days before death falling to the range of 96°–94°. The pulse at entrance was 80 to 90, once reaching 102, but gradually decreased to 65, where it remained until 3 hours before death when it went to 101. Became impalpable an hour before death. The respiratory rate was usually 24–28, but on the day of death was 15 and very labored.

On the morning of October 15 the patient was unconscious, with labored breathing and impalpable pulse. Death occurred at 11 35 A.M.

A clinical diagnosis of obstructive jaundice (malignant?) was given. The autopsy was performed by me at 8 P.M. of the same day. The postmortem findings are taken in a condensed form from the laboratory protocol.

Autopsy Protocol.—Body below average height, fairly well built. Fair amount of panniculus. The muscles are small. Rigor mortis is present throughout. The body heat is absent. There is moderate edema over the lower extremities, slight over the thorax. The skin is icteric throughout, of a brownish-yellow to a dark grayish-green over the trunk, grayish-green over the upper part of the face, dark brownish-green over chin and neck. The hands, wrists, and lower half of forearms are irregularly pigmented, dark brown patches alternating with lighter ones. The pigmentation appears darkest around the light areas, which are pale grayish-white in color and are smoother and more translucent than the surrounding pigmented skin. The light areas are largest and most numerous over the dorsum of the first and second phalanges. The skin over the flexor surfaces and genitals is much more heavily pigmented than over the remaining portions of the body. Over the thorax there are blister-marks showing a deep brownish green pigmentation. There is desquamation of the epidermis over these areas. The sclerae are dark lemon-yellow. Throughout the skin, especially over the thighs, there are numerous punctate ecchymoses. There is moderate hypostasis over the back. The mucous membrane of the mouth is grayish-brown. The examination of the teeth is negative. There is a very offensive odor from mouth and nose.

The examination of the brain is negative.

The spinal cord not examined.

The diaphragm on the right reaches to the lower border of the fourth rib; on the left to the lower border of the fifth rib.

Heart.—The pericardial sac contains about 50 cc. of brownish fluid. There is a small 'soldier's spot' on the anterior wall of the left ventricle. The auricles are much dilated and filled with white clots. The mitral and aortic flaps are slightly thickened. Otherwise the examination of the heart is negative.

Lungs.—There are about 200 cc. of dark brownish fluid in the

¹ Dr. Dock at first thought that the pigmentation might be the intensification of a previously-acquired tan which is so frequently seen in severe icterus. Careful inquiry showed that the patient had not been tanned, and that the pigmentation was of recent development. This is also borne out by the microscopical appearances.

left pleural cavity. The left pleurae are free, with the exception of a few adhesions at base. The right pleurae are adherent throughout. No fluid in the right pleural cavity. The left lung is voluminous. It is heavily pigmented. The lower lobe shows marked hypostasis. The pleural surface is clear, shining, and smooth. Everywhere throughout the surface are small, flattened, grayish nodules, varying in size from a pinhead to a bean. They are firm and show no umbilication. They are subpleural, have no hyperemic zone, but each little nodule is outlined by a narrow ring of anthracosis. On section the upper lobe is grayish-pink, the lower one dark red. On slight pressure an abundant foamy fluid exudes. All through the parenchyma are scattered small grayish nodules. They are most abundant in the lower lobe. The right lung is covered with stringy adhesions, and the pleura is thickened throughout. Beneath the pleura are numerous small nodules resembling those in the pleura of the left lung. The nodules are not so numerous but are larger, one as large as a five-cent piece.

The bronchi, trachea, and esophagus are filled with a foul-smelling brownish-red fluid. The thyroid gland is enlarged and cystic. The examination of the thoracic duct is negative.

Abdominal Cavity.—This contains about 1½ liters of dark brown bile-stained fluid which has no odor. The omentum is moderately rich in fat. It is rolled up to the level of the umbilicus, and is filled with tumor nodules which on section are grayish in color and of a firm consistency. It is adherent to the anterior abdominal wall and to the liver. These adhesions are about as thick as a thumb and contain tumor nodules.

Liver.—The liver is adherent by numerous adhesions to the omentum, stomach, colon, and along its lower edge to the anterior abdominal wall. It is enlarged, its anteroposterior diameter being greatly increased, so that its shape is almost round. It weighs about 5 pounds (The exact weight could not be determined as the specimen was prepared for museum purposes with other organs attached.) Its capsule is thickened and in many places covered with stringy adhesions. Through the capsule can be seen many nodules of new growth, varying in size from a pea to a quarter of a dollar. The large nodules show distinct umbilication, and possess hyperemic borders. The small ones are grayish or creamy in color. On section the liver-parenchyma is bronzed-green; scattered through it are many grayish-yellow tumor nodules, the largest about the size of a dollar. The cut surface of these nodules is almost homogeneous, of fairly firm consistency, but yields an abundant exudate on scraping. Some of the largest nodules contain colloid areas. The majority of the nodules are in the branches of Glisson's capsule, around the portal veins. The cut surface of the liver is dull-shining or cloudy. The lobules are increased in size, their outlines are distinct. The center of the lobules is dark green or bronze, the periphery a pale grayish green. The larger bile ducts are filled with thick bile. The blood-vessels are only moderately filled with blood.

Gallbladder.—The gallbladder can not be seen, as the omentum and colon are adherent to the edge of the liver at its site. On separating the omentum by tearing the adhesions which are not very firm the colon is found to cover up the site of the gallbladder. The colon is next opened longitudinally. At the location of the adhesions between the colon and the liver there is in the mucosa of the colon a firm reddish elevation about the size of a five-cent piece. The mucosa over the elevation appears intact. The colon is then carefully separated from the liver by tearing the adhesions which are not very firm. The gallbladder is then found to be greatly retracted within the liver-substance, and is surrounded by a nodular mass of new growth. A vertical incision is now made through the liver and gallbladder. The latter is found to consist of a cavity about the size of a pigeon's egg, containing a thick, dark reddish-brown fluid. The wall of the cavity is thick, firm, grayish-yellow in color, and passes insensibly into the nodular mass of new growth surrounding it. This new growth extends upwards, tree-like, along the bile-vessels into the liver. The inner surface of the cavity is polypoid. No distinct bladder-wall can be made out, its structure being replaced by a diffuse new growth. Just above the site of the gallbladder and directly continuous with the wall of its cavity is a mass of growth of the size of a silver dollar. It is firm, shows abundant stroma, and contains small colloid areas. On scraping a rich cellular

exudate is obtained. The cystic duct is patent for about one inch but has no communications. The common duct is surrounded by a mass of adhesions containing nodules of new growth. In this tissue near the gallbladder are two small irregular calculi of bile-pigment firmly encysted in the connective tissue. The lumen of the common duct is completely obliterated. The papilla is enlarged, firm; there is no opening into the common duct, but the pancreatic duct is patent. The portal vein is surrounded by a mass of connective tissue through which run strands of new growth. There is no narrowing of its lumen.

Adrenals.—The right adrenal is surrounded by a thick mass of connective tissue which unites it firmly to the liver and the gallbladder. In this tissue a small irregular calculus of bile-pigment about the size of a pea is encysted. The adrenal is of normal size, firm, and shows no postmortem change in its medullary portion. The left adrenal is of normal size; its medullary portion grayish and firm, showing no postmortem change (To the naked eye neither adrenal gave any appearance of the presence of new growth.)

Pancreas.—The pancreas is shorter than normal, its length being 18 cm., but is much thicker, 6 cm. Its breadth is also increased so that its shape is almost round (cylindrical). It weighs 200 grms. Its consistency is very firm, its color pale ochre-yellow. On section the lobules are increased in size, their outline distinct. The cut surface is shining, homogeneous and of a dull ochre color. The interlobular fat is in small amount. In many of the interlobular septums there are reddish areas of congestion or hemorrhage. The large bloodvessels are empty. The duct of Wirsung is patent. No nodules of new growth are observed in the organ.

Lymph-glands.—The mesenteric and retroperitoneal lymph-glands contain nodules of new growth similar to those in liver and omentum.

Spleen.—The spleen is slightly enlarged, weighs 246 grms. Its consistency is decreased. No nodules of new growth are seen in it.

Kidneys.—Both kidneys are enlarged and swollen, being much plumper than normal. The capsule strips off very easily. The surface of the cortex is smooth, grayish-green in color. On section the cut surface is bright gray green with reddish stripes and points. The cortex is 12 mm. in thickness, and is of a dull, cloudy appearance. The straight tubules of the medulla appear as bright grass-green stripes. The pelvis shows no change.

The examination of the ureters, bladder, and genital organs is negative.

Appendix.—This is surrounded by old adhesions. It is short and much narrowed above. Near the tip is a firm nodule of the size of a small hazel-nut.

Rectum.—The mucosa of the rectum shows numerous small ulcerations and hemorrhages. The large and small intestines contain foul, colorless, soft or semifluid fecal material.

The examination of remaining portions of body is negative except that all tissues are stained with bile-pigment.

MICROSCOPIC EXAMINATION.—The sections from the primary growth in the wall of the gallbladder show the structure of an adenocarcinoma. In the peripheral portions of the tumor the adenomatous character of the growth is more marked than in the older areas where it bears more of the character of a medullary carcinoma. The connective tissue spaces are filled with polymorphous cells of varying sizes; the cells immediately lining the walls of the spaces are distinctly columnar. In many of the spaces the cells have undergone mucous degeneration or simple necrosis, so that the resulting appearance is that of a gland lumen filled with mucus or granular debris. Some areas of limited extent show a more marked mucous change (colloid areas). The cells immediately lining the alveolar spaces are everywhere distinctly columnar and possess round or oval nuclei which are two to three times as large as the nucleus of a liver-cell, and stain a very bright deep blue with hematoxylin. The tumor cells are larger than the columnar cells of the bile-ducts and their nuclei are also larger and more deeply staining. The loose cells in the lumen of the spaces are irregular in size and form, their nuclei present varying stages of degeneration and necrosis. Cell-division figures are found in the peripheral cells. No trace of the structure of the gallbladder wall found.

Liver.—The liver lobules are atrophic, the connective

tissue is increased. The liver cells are atrophic, but show marked cloudy swelling in the central portion of the lobules. Many show hypertrophic nuclei. There is much bile-pigment in and between the liver-cells, especially in the central portion of the lobule. The larger bile-ducts are distended with golden yellow pigment. The central veins are congested. The tumor nodules found throughout the liver show the same structure as the gallbladder tumor. The majority of the nodules arise in Glisson's capsule, and small nests of tumor-cells are found in the periportal connective-tissue in every part of the liver. The metastasis is chiefly lymphatic, through the periportal lymph-spaces, but there is also direct extension or retrograde metastasis through the larger bile-ducts, some of which contain tumor masses. In other cases there is a hematogenous metastasis through the branches of the portal, but this is limited. Though the majority of the nodules arise in Glisson's capsule and have infiltrated only the peripheral portions of the neighboring lobules, the largest ones extend through the lobules to the central vein, in some instances completely replacing a number of lobules.

Lung.—The nodules found throughout the lung and beneath the pleurae are of the same type of growth as those in the liver and gallbladder. They are found everywhere throughout both lungs, the metastases being both lymphogenous and hematogenous. Numerous small hemorrhagic infarcts are also found, and there is extreme congestion and edema. The bronchial lymph-glands contain tumor nodules of similar structure.

Omentum.—The nodules found in the omentum and in the mesenteric and retroperitoneal lymph-glands are the same type of new growth as those found in gallbladder, liver, and lung. The adenomatous character of the growth is well-preserved.

Adrenals.—In the adhesions surrounding the right adrenal there are numerous small nests of tumor-cells filling up the lymph-spaces. These can be traced through the capsule of the right adrenal and along the bloodvessels into the medullary portion of the organ. This is almost completely replaced by tumor growth of the same type as that in the gallbladder. Throughout the cortex of the adrenal there are a number of small nests of tumor cells. The left adrenal shows a similar condition, the medullary portion being almost completely replaced by new growth of the same type as that found elsewhere. A few small scattered nests are also found in the cortex. There is excessive pigmentation (hemosiderin) of the cortical cells in both adrenals. Nests of tumor-cells are found in the connective tissue about one of the ganglia of the capsule of the right adrenal. There is also a slight leukocyte infiltration in and about this ganglion. The lymph-spaces about the semilunar ganglion also contain nests of tumor-cells and the surrounding tissue shows small foci of leukocyte infiltration.

Colon.—Sections of the wall of the colon made at the point of adhesion to the gallbladder-tumor show an infiltration of the wall of the intestine by carcinoma cells of the same type as those of the gallbladder tumor. The growth extends entirely through the muscularis and mucosa, presenting an ulcerating surface (not perceptible in the gross specimen).

Appendix.—The small nodule in the appendix consists of tumor growth of the same character as that found in the other organs. The lumen of the appendix is entirely obliterated above the tumor nodule, being replaced by scar-tissue.

Pancreas.—There is hypertrophy of the lobules with marked hypertrophy of some of the areas of Langerhans. The interlobular connective tissue is edematous and contains numerous areas of leukocyte-infiltration associated with marked congestion and small hemorrhages. No new growth is found in any part of the organ. (See below.)

Kidneys.—Sections of the kidneys show extreme cloudy swelling of the cells of the convoluted tubules. These are deeply stained with bile-pigment. The straight tubules are for the most part filled with greenish-yellow casts of bile-pigment. There are scattered areas of connective tissue increase throughout the cortex containing a few obliterated glomeruli. In the lymph-spaces of the subpelvic connective tissue and around the main branches of the renal vessels there are small nests of tumor-cells of the same type as found elsewhere.

Skin.—Sections taken from the skin of the dorsum of the

fingers show areas of excessive melanosis of the rete alternating with areas in which the rete contains no pigment. In these nonpigmented areas the epidermis is thinner and there is a complete disappearance of the papillae of the dermis. (See below.)

Spleen.—Sections of the spleen show chronic congestion and atrophy. No tumor secondaries found.

Heart.—The sections show brown atrophy. Throughout the heart-muscle there are scattered areas of leukocyte-infiltration.

Pathologic Diagnosis.—From the postmortem findings and the microscopic study the following pathologic diagnosis is obtained.

Primary adenocarcinoma of the gallbladder with secondaries in liver, lungs, adrenals, omentum, colon, appendix, kidneys, mesenteric, and retroperitoneal lymph-glands; obstructive jaundice, cholelithiasis, parenchymatous degeneration of liver and kidneys; hypertrophy and inflammation of pancreas; edema, congestion, and hemorrhagic infarction of lungs; brown atrophy of heart; chronic congestion of spleen; melanosis of skin (Addison's); vitiligo.

[To be concluded.]

THE ACTION OF RENNIN UPON MILK-DIGESTION.

By I. H. CORIAT,

of Boston, Mass.

Assistant in Medical Chemistry, Tufts College Medical School, Boston.

[From the Chemical Laboratory of Tufts College Medical School.]

FROM time immemorial the curdling of milk in the manufacture of cheese by rennet, or what was formerly used, the infusion from a calf's stomach, which contained the coagulating enzyme, has been known. In the Bible it is several times alluded to, while in the making of cheese this action was a process well known to the ancients. It was also observed, that when milk became sour, a curd was formed, which curd and souring process was considered formed by an action analogous to, if not exactly identical with, that produced by the rennet enzyme. In fact, the identity of the two processes was strongly and positively argued and defended by many eminent chemists, even of the present century. It was not, however, until modern physiologic chemistry had begun to be built upon its present basis, and overthrown timeworn ideas, that the existence of a separate coagulating enzyme in the gastric contents, apart from pepsin, began to be suspected.

Berzelius, the Swedish chemist, in 1840, was one of the first to distinguish the souring of milk from the action of the rennin enzyme.¹ He believed, however, that this enzyme acted by changing the lactose into lactic acid—and, in virtue of this acid reaction, the casein was precipitated as a curd.

Selmi,² Lehmann³ and Heintz⁴ showed, however, that this reaction was independent of any acid formation. Voelcher⁵ found that rennet could curdle milk that had been made distinctly alkaline, and that after separation of the curd, the whey would be distinctly alkaline, thus showing that the formation of lactic acid was entirely unnecessary. Sohxlet⁶ defended the lactic acid theory, and claimed that the only difference between coagulation by rennet and spontaneous coagulation, was, that with the former lactic acid was formed more quickly. Hallier thought that the organisms in a calf's stomach were the cause of coagulation, and that the penicillium would curdle milk as quickly as rennet. Liebig believed that as soon as a decomposition of the stomach mucous membrane had begun, lactose was changed into lactic acid, which would neutralize the alkali which kept the casein dissolved, and precipitate it as an insol-

uble curd. Deschamps⁷ was the first one to obtain the active principle of rennet extracts, which he termed chymosin. This isolation, impure and crude as it was, was a step in the right direction.

But it remained for Hammarsten to show that the curdling power of the gastric juice was due to as true an independent enzyme as pepsin—that as truly as pepsin was proteolytic, this enzyme was coagulating—and that the coagulating process was entirely independent of any change of the lactose, or any acid production. In three masterly papers⁸ his results were published. In his first paper (1872) he showed that not only was the action entirely independent of lactose and affected the casein alone—but that it was independent of any acid formation—and that no change in reaction took place during the curdling process. He succeeded in separating the active principle from its contamination with pepsin—and called this enzyme lab. Later (1874) he investigated the nature of the chemical action of this lab-enzyme—showing that it split casein into a soluble and an insoluble portion. He also proved that the presence of calcium salts—preferably calcium phosphate—was necessary for coagulation. In the third paper (1877) he obtained the enzyme in an absolutely pure state—and showed that other salts could take the place of calcium. He believed that the curdling of milk was a process analogous to the clotting of blood. The matter practically rests here; for since then, other observers have simply confirmed Hammarsten's views, adding a little now and then, as the results of original investigation.

It has long been known that milk would curdle when it became "sour"—the curdling being due to the acid reaction of fermentation lactic acid derived from lactose, by specific organized ferments. Milk may also be coagulated by the direct action of certain microorganisms, *i. e.*, the *Bacillus acidi lactici*, which produces lactic acid from lactose—and the *Bacillus butyricus*—the microorganism of butyric acid fermentation. As the pathogenic bacteria produce soluble poisonous chemical enzymes (diphtheria and tetanus), so Duclaux removed the coagulating bacteria from their growth in culture media by filtering through unglazed porcelain, and obtained a filtrate that was bacteria-free. This filtrate was very active in curdling milk. The plant kingdom contains enzymes that coagulate milk, some by virtue of their acidity, and some *per se*. Among these may be mentioned the leaves of the artichoke, the seeds of black pepper, the juice of the figtree and pineapple.

Friedburg, however, has doubted that the coagulating action of animal and vegetable enzymes is the same,⁹ but further on in this paper an effort will be made to establish their identity. An enzyme also has been found in the human pancreas and in that of certain herbivora, which causes the coagulation of neutral or alkaline milk. This action, however, is seldom called into play, except under certain pathologic conditions, as the rennin of the stomach has already performed its function before the milk reaches the duodenum.

Milk may then be coagulated:

1. By direct bacterial action.
2. By indirect bacterial action producing lactic and butyric acids.
3. By the addition of acids.
4. By soluble bacterial enzymes, in solutions free from bacteria.
5. By vegetable coagulating enzymes.
6. By animal coagulating enzymes.

Rennin, then, is a true animal enzyme, as absolute and independent as pepsin, and like pepsin and trypsin it exists preformed in the cells as a proenzyme (Labzymozen). This proenzyme itself has no action on milk, but on the addition of acids, especially HCl, it is converted into the active enzyme. It is formed in the stomach by the glands of the fundus and pylorus. It is never absent in strictly physiologic conditions, but the fasting human stomach contains less rennin than when it is digesting. In animals the opposite holds true.¹⁰ Pathologically it is absent in atrophy of the gastric mucosa, in chronic mucous gastritis and in gastric cancer.

According to Hammarsten pure rennin (lab) gives the following reactions:

Xantho-proteic	negative.
Alcohol	no pp.
HNO ₃	no pp.
Tannin	no pp.
Iodin	no pp.
Normal lead acetate.....	no pp.
Basic lead acetate	pp.

Impure rennin is precipitated by the above reagents. Rennin, like pepsin, when in a pure state does not respond to the ordinary proteid reactions. It is soluble in water, but the watery solution does not coagulate on boiling. It is destroyed by alcohol and by long digestion in acid solutions, while on the contrary, a short contact with acid makes the action more energetic. It acts in the presence of almost any acid—hydrochloric acting best, while lactic, acetic, sulfuric, and phosphoric acids come next in the order named.¹¹ Fixed caustic alkalies have a powerful destructive action—it is also destroyed by a 0.5 to 1% solution Na₂CO₃—and the action is hindered in the presence of disodium phosphate. Like all enzymes, the action of rennin is destroyed by boiling.

The principal differences between rennin and pepsin is best shown by a table:

TABLE I.

Rennin.	Pepsin.
1. Coagulates milk and pure solutions of casein free from lactose.	1. Does not, when pure, coagulate milk.
2. No digestive effect on proteids.	2. Digests proteids, changing them to albumose-peptone.
3. Acts in neutral, alkaline, or acid solutions.	3. Acts only in acid solutions.
4. Precipitates casein, but does not digest it.	4. Digests casein, but does not precipitate it.
5. Splits casein into a soluble whey proteid, and an insoluble paracasein.	5. Splits casein into a soluble albumin, easily digested—and an insoluble pseudonuclein, digested with difficulty.
6. Calcium salts must be present for rennin action.	6. The presence of calcium salts is indifferent.
7. Destroyed in the presence of 3 p.m. HCl at 37 to 40° C. for 24 hours.	7. Not destroyed under the same conditions.
8. Incompletely precipitated by magnesium carbonate.	8. Completely precipitated by magnesium carbonate.

If milk be treated with dilute acids (*i. e.*, acetic)—the casein is precipitated as such—the precipitate being soluble in an excess of the acid. This precipitate, as also the commercial preparations of dry, powdered casein which are made by acid precipitation—may be redissolved in slightly alkaline solutions, or by the aid of neutral or alkaline salts. These solutions can be

curdled with rennin. This shows that the curd formed by the action of dilute acids differs in composition from the curd formed by rennin.

The curdling of milk by rennin seems to be a process analogous to the clotting of blood—for rennin or its proenzyme, needs, like the fibrin enzyme or its antecedent prothrombin,—the presence of calcium salts. In fact, milk from which the calcium salts have been precipitated by ammonium oxalate will not curdle at all. The chemical process of rennin coagulation seems to show that the casein is split partly into a difficultly soluble body paracasein, which resembles casein in composition, and partly into a soluble albumose-like body—whey proteid. The resulting curd carries down with it large amounts of calcium phosphate and the milk fat. Casein is a protein substance, belonging to the nucleo-albumins, and differs from most proteins by containing phosphorus and iron. In casein-digestion by pepsin—hydrochloric acid an insoluble residue of pseudonuclein remains behind, while the albuminous molecule goes through the ordinary steps of digestion, forming eventually albumose-peptone. Trypsin, however, can digest the casein pseudonuclein.

We have thus far seen that rennin is an independent enzyme, distinct from pepsin, and that it possesses a definite action on solutions of casein, or on casein in milk, precipitating it as a definite insoluble chemical compound or curd. We have also seen that enzymes exist in the plant kingdom, and also bacterial enzymes, which possess a coagulating action, almost, if not exactly identical with that of rennin. Casein and milk alone can be digested without rennin being present, or, in other words, the curdling of milk is not necessary for its digestion. The question now arises, why then, does rennin exist if milk (or casein) can be digested without its aid, or in other words, if pepsin alone can split up casein into albumen and pseudonuclein, how does rennin-action contribute to the further conversion into soluble proteids? Some reason must be necessary for this curd-formation, and it occurred to the writer that probably this precipitation had something to do with peptone production. To this end the following experiments were undertaken, with pepsin and pancreatin—in each case both with and without the addition of rennin. The samples of milk used were the same in all experiments.

FIRST SERIES.

Milk digestion with pepsin alone.

The following solutions were made up:

- No. 1.
100 cc. digestive HCl (2.5 per M.)
10 cc. milk.
 $\frac{1}{16}$ gm. pepsin
Digested for 24 hours at 40° C.
- No. 2.
100 cc. digestive HCl.
20 cc. milk.
 $\frac{1}{2}$ gm. pepsin.
Digested for 24 hours at 40° C.

Each of these solutions was placed in a flask, and digested for 24 hours at 40° C. At the end of that time the solutions were made alkaline with sodium carbonate and warmed over a water bath, to remove the undigested acid albumin and nuclein, and to stop all further action of the enzymes. The solution was then filtered, the precipitate washed with water, and the filtrate concentrated to about 10 cc. This filtrate contained the digested albumin as albumose-peptone, while the undigested acid albumin and the pseudonuclein remained behind on the filter paper. No effort was made to determine the amount of digested lactalbumin

separately from the casein. This, however, was no source of error in the determination of total digested proteid as the increase would bear the same ratio to the casein in all the determinations, both with and without rennin. The nitrogen was then estimated in the filtrate according to Kjeldahl's method, and the result multiplied by the factor 6.38, the product being the amount of digested proteid.

RESULTS.

- No. 1.
Amount of nitrogen .0476 gm.
.0476 \times 6.38 = .3036 gm. digested casein, as albumose-peptone.
- No. 2.
Amount of nitrogen .0644 gm.
.0644 \times 6.38 = .4108 gm. digested casein, as albumose-peptone.

SECOND SERIES.

Milk digested with pepsin and rennin.

The same experiments were repeated as above, under exactly the same conditions of amounts, temperature, and time—but with the addition of rennin. The rennin used was in liquid form.

- No. 3.
100 cc. digestive HCl.
 $\frac{1}{16}$ gm. pepsin.
10 cc. milk.
1 cc. rennin.
Digested at 40° C. for 24 hours.
- No. 4.
100 cc. digestive HCl.
 $\frac{1}{2}$ gm. pepsin.
20 cc. milk.
2 cc. rennin.
Digested at 40° C. for 24 hours.

RESULTS.

- No. 3.
Amount of nitrogen .049 gm.
.049 \times 6.38 = .3126 gm. digested casein, as albumose-peptone.
- No. 4.
Amount of nitrogen .126 gm.
.126 \times 6.38 = .8038 gm. digested casein as albumose-peptone.

As one proteolytic enzyme gave such favorable results in increased peptone-production with rennin, it was deemed advisable to try the casein-digesting power of pancreatin, with and without rennin, under the like conditions of amounts, temperature and time.

THIRD SERIES.

Milk digested with pancreatin alone.

- No. 5.
100 cc. water.
1 cc. saturated Na_2CO_3 sol.
 $\frac{1}{16}$ gram pancreatin.
10 cc. milk.
Digested at 40° C for 24 hours.
- No. 6.
100 cc. water.
2 cc. saturated Na_2CO_3 sol.
 $\frac{1}{2}$ gram pancreatin
20 cc. milk.
Digested at 40° C for 24 hours.

At the end of digestion, the undigested alkali albumin and pseudonuclein was precipitated by acetic acid and warming, the same as for pepsin,—filtered, and the filtrate concentrated to about 10 cc. as above. The nitrogen was estimated by Kjeldahl's method.

RESULTS.

- No. 5.
Amount of nitrogen—.042 grams.
.042 \times 6.38 = .2679 grams digested casein as albumose-peptone.

No. 6.
Amount of nitrogen—.1036 grams.
.1036 × 6.36 = .6609 grams digested casein as albumose-peptone.

FOURTH SERIES.

Milk digested with pancreatin and rennin.

No. 7.
100 cc. water.
1 cc. saturated Na₂CO₃ sol.
 $\frac{1}{8}$ gram pancreatin.
1 cc. rennin.
10 cc. milk.
Digested at 40°C for 24 hours.

No. 8.
100 cc. water.
2 cc. saturated Na₂CO₃ sol.
 $\frac{1}{2}$ gram pancreatin.
2 cc. rennin.
20 cc. milk.

RESULTS.

No. 7.
Amount of nitrogen—.0504 gms.
.0504 × 6.38 = .3215 gms. digested casein as albumose-peptone.

No. 8.
Amount of nitrogen—.1246 gms.
.1246 × 6.38 = .7949 gms. digested casein as albumose-peptone.

The results of the above experiments may be thus tabulated :

TABLE II.

Without Rennin.

Enzyme.	Nitrogen.	Albumose-peptone.
Pepsin..... No. 1	.0476 gm.	.3036 gm.
Pepsin..... No. 2	.0644 gm.	.4108 gm.
Pancreatin..... No. 5	.042 gm.	.2679 gm.
Pancreatin..... No. 6	.1036 gm.	.6609 gm.

TABLE III.

With Rennin.

Enzyme.	Nitrogen.	Albumose-peptone.
Pepsin..... No. 3	.049 gm.	.3126 gm.
Pepsin..... No. 4	.126 gm.	.8038 gm.
Pancreatin..... No. 7	.0504 gm.	.3125 gm.
Pancreatin..... No. 8	.1246 gm.	.7949 gm.

[To be concluded.]

A CASE OF MYOMA OF THE BLADDER.

By OTTO G. RAMSAY, M.D.,
of Baltimore, Md.

Instructor in Gynecology, Johns Hopkins University.

New growths of the bladder, and especially myomata of this organ, are of such comparative rarity that it seems the duty of each one of us, if we have an opportunity, to add any such cases to the literature of the subject. The following case operated upon by Dr. H. A. Kelly in the Gynecological Clinic of the Johns Hopkins Hospital merits for this reason a report in full as illustrating a typical example of pure myoma of the bladder.

Mrs. E. I., white, aged 38, was admitted to the Gynecological Department of the Hospital on October 26, 1898, suffering with frequent and painful micturition and general weakness. She gave no family history of neoplasms or tuberculosis, and she herself has never had any serious illness before the present one.

During the past two years she has complained of bladder symptoms, consisting of frequent micturition, vesical tenesmus and pain, occurring at irregular intervals and lasting one or two weeks.

Only since March, 1898, have these symptoms been severe, and since this time the severity of the pain has increased greatly, becoming like labor pains in character. In July, 1898, a suprapubic cystotomy was done, but the tumor discovered in the bladder was not removed. Following this the patient has had almost constant severe pain due to the violent efforts to extrude the tumor. She has suffered also from a purulent cystitis, and has had three distinct vesical hemorrhages, losing at least a quart of blood in each one. The patient had always been of a nervous temperament, but showed no signs of mental excitement until three weeks before admission, when her friends noticed that she was getting queer. This "queerness" increased, and on the day of admission to the hospital she became much excited and harbored delusions of various kinds.

On examination a marked bulging of the whole anterior vaginal wall was discovered, and a rounded tumor about the size of a baseball could be felt by bimanual palpation lying in the bladder. A male sound passed into the bladder demonstrated the tumor to be attached to the left vesical hemisphere by a broad base, covering an area 5 by 6 cm. in diameter. The neck of the bladder and urethra were obliterated from the violent efforts to expel the tumor, and the sound entered directly into the bladder from the external urethral orifice.

The urine was of a yellow color, with thick dirty-white precipitate. Specific gravity 1015, acid in reaction, and containing much albumin. The microscope showed masses of pus-cells and numberless red blood-corpuscles.

Operation.—The first operation consisted in the formation of a vesicovaginal fistula both to facilitate drainage and to allow a more thorough irrigation as a preparation for later enucleation. To do this an incision 3 cm. long was made through the vesicovaginal septum and the vesical mucosa stitched to the vaginal mucosa, giving good drainage and allowing the escape of several large blood-clots and considerable bloody urine. On palpating the tumor through this opening it was found elastic, edematous, and everywhere smooth, with a sessile base, as previously outlined by the bladder sound.

Two days later the whole tumor was removed through the vesicovaginal fistula. Strong morcellation forceps were introduced into the bladder through the vesicovaginal fistula and the tumor grasped. By firm traction it was drawn through the fistula into the vagina, and then delivered outside of the vulva, practically turning the bladder inside out for the time being. The capsule was incised and dissected off, several large vessels being cut and tied during this process. Several large vessels were also found at the point of attachment, which was broad but distinctly pedunculated. Oozing in this area was easily controlled by passing several catgut sutures through the vesical tissues.

After the tumor was removed the bladder was thoroughly irrigated and one piece of iodoform gauze introduced into it through the vesicovaginal fistula which was left open. The duration of the operation was 32 minutes, and the condition of the patient after its completion was better than it was before the anesthesia was begun.

Following the operation much difficulty was experienced in managing the patient, who was absolutely irresponsible, refusing all nourishment and requiring to be fed with stomach tube. For hours she would not speak, simply lying with eyes turned toward the ceiling, at other times she was perfectly intractable. The temperature remained normal throughout the convalescence, the pulse rate ranged between 100 and 140, and the vesicovaginal fistula slowly closed, though on her discharge there was still some incontinence.

A note was made on her discharge that she was much improved in every way; later a letter from her family advised us of her death, though no cause was given.

Pathologic Description.—The specimen removed consists of a tumor 9 x 8 x 5 cm. Its surface is slightly lobulated and roughened, presenting tags of tissue where it was separated from its capsule. On one surface is an area 5 x 3.5 cm. covered by bladder mucosa. On section the cut surfaces of the tumor have a transparent appearance and consist of coarse fibers which show a definite concentric arrangement.

Microscopic Examination.—The tumor is composed of bundles of smooth muscle, cut transversely and longitudinally. These are separated from one another by a small amount of fibrillated tissue which contains a few blood-vessels of moderate size. In many places the myomatous tissue shows commencing hyalin degeneration and areas of edema. Toward the free surface of the tumor the hyalin degeneration is more marked and there is a slight, small round-cell infiltration of the tissues. There is also a considerable deposit of yellow granular pigment which is both intracellular and extracellular. The surface epithelium of the bladder mucous membrane has for the most part been destroyed, the mucosa presenting a granulating surface consisting of newly-formed blood-cells, young connective tissue cells, polymorphonuclear cells, and in the depths numerous small round cells.

Anatomic Diagnosis.—Myoma of the bladder-wall. Chronic cystitis with localized ulceration.

Several surgeons have reported on myomas of the bladder, and there are also a few single cases appearing in the literature of various countries, and from these in connection with our own case an idea of the general course of this new growth may be obtained.

These tumors appear to take origin from the unstriped muscle-tissue of the bladder-wall, and in their histologic structure are almost exactly similar to the common myomas of the uterus.

Their mode of origin is still a question of conjecture, and there must certainly be some special influence determining their development. This is indicated by their extreme rarity, which points to some rare influence acting but seldom, or to some abnormal condition of the bladder-wall. The possibility of their origin from a partially atrophied displaced Müller's duct has been discussed, but they show no glandular tissue as do the myomas of the uterus which are attributed to this duct. Another possible source of origin has been suggested in the uterus masculinus, but this cannot be the true point of origin, both because of their varied disposition in the bladder-wall, and more important, because they are also found in females in whom the uterus masculinus is not present, nor is there in the female bladder or urethra any organ of similar structure. The effects of chronic inflammation acting as an irritant to induce an hypertrophy of the vesical muscle must also be left out of consideration, as in most of the cases the cystitis is a late symptom. We are therefore forced to concede our want of knowledge in this direction, and conclude that the cause of origin is probably some unexplained congenital abnormality or that the neoplasm is due to the action of an unknown nervous or other influence.

The situation of the myoma in the bladder and the direction of growth vary, and we find two distinct varieties, namely, the tumor may project into the cavity of the bladder as a sessile or pedunculate mass, or it may, on the other hand, project from the outer surface of the bladder into the peritoneal cavity, covered by the peritoneum, or, in simpler words, they are either submucous or subserous.

There is also a third method of growth, a diffuse infiltration of a greater or less portion of the bladder-wall by the myomatous tissue, though probably this form is always amyosarcoma and not a pure myoma.

The portion of the bladder most frequently the seat of the growth is, according to Terrier and Hartmann,¹ the trigonum, which was the site in 6 cases out of 15. Terrier and Hartmann's figures must however be considered somewhat carefully, for though they claim to eliminate all cases which are not pure myomas in a series collected by them, they include several which, from the pathologic structure, as well as the tendency to return after removal, should be classed rather as sarcomas than as the benign myomas. Next in frequency is the anterior vesical wall, then the posterior and lateral walls.

Terrier and Hartmann quote 4 cases out of 16 in which the growth was subserous, extending into the peritoneal cavity, or into the cellular tissue around the bladder, and to this must be added a case reported by Verhoogen,² in which the tumor was attached by a wide base in the area between the seminal vesicles and filled almost entirely the bony pelvis, extending upward nearly to umbilicus.

Histology.—These tumors, as their name imports, are made up chiefly of unstriped muscle-tissue, lying in interlacing bands, held together by a variable amount of connective tissue, in which are found a number of small bloodvessels. They are usually rounded in shape, and perhaps divided by shallow sulci into lobules, and in the submucous variety are covered by the mucous membrane of the bladder. The base or pedicle varies greatly in size and the muscle-fibers composing it can generally be traced directly into the muscular fibers of the vesical wall proper. Several quite large vessels are usually found entering the tumor at this spot, though, fortunately, the blood-supply of these growths, like the uterine myomas, is generally scanty. On section they are pinkish or whitish in color and have a peculiar translucent appearance and appear to be made up of concentric or irregularly placed coarse bands of muscle. Hyaline degeneration of portions of the growth are often described, as well as localized edema. Calcification has also occurred, Socin³ reporting a splendid example of this form of degeneration, in which a myoma the size of a large nut was found as a calcified mass.

On microscopic examination the picture is usually simply of numerous bands of smooth muscle-fibers, running in various directions, and therefore showing in the microscopic field under observation, muscle-cells cut in various directions—transversely, obliquely, etc. These bands are held together by a varying amount of fibrillated connective tissue in which lie several bloodvessels. If there is any cystitis or inflammation of the surrounding structures the growth may show a round-cell infiltration. Areas of hyaline degeneration appear as homogeneously staining spots in which the individual cells are not to be differentiated. This is the appearance of the myomas, and serves to differentiate the benign tumor from sarcomas, which in this region often takes the form of myosarcomas. In the case of the myosarcomas, the muscle-cells are larger and more irregular in form and arrangement, and there are clumps or irregular areas of round cells, among which are quite numerous bloodvessels. Giant cells or round cells of extremely irregular shape and size are also apt to be present.

The Medical Missionaries in China.—The many relatives and friends of the medical missionaries in China—some of whom are from this city and vicinity—have been enduring that hope deferred that maketh the heart sick. At this writing this devoted band of young men and women are in grave peril or already massacred. The anxiety and love of friends are even overshadowed by the apprehensions felt by the whole country that when this ominous veil of Chinese duplicity is lifted, the hideous reality may be too bad to tell. Let us hope in the name of a common humanity that some force has been found great enough to stay the hand of the Chinese avenger.

The medical work of most foreign missions has become an important factor in their success. It is no longer a mere evangel upon which the missionary relies, but he seeks (and wisely seeks) the cooperation of scientific medicine. It is this, far more than the abstract teachings of theology, that appeals to the poor native while it holds out to him the hand of a material help which he can readily understand. The Christian missions in this respect are true to the traditions of their faith, for Christianity from its earliest days has always sought to identify itself with healing. In recognizing scientific medicine, and deferring to it, and still more by associating some of its earnest and talented practitioners with them in their work, the missionaries have shown that they themselves are capable of true progress and are not likely to be, as some of them in an older generation were, the victims of strange delusions. This work of the medical missionary cannot be other than salutary not only to the cause of his church but also of his profession. Whither he goes, there we may be sure will go a measure of light and benevolence and good work and real science that will be indeed for the uplifting of the nations. Some of these medical men in foreign fields have already done important scientific work, and they have always been evangelists of health and morality. To the prejudice and opposition—not unnatural—of natives, tenacious of their own creeds, they present the teachings and the practice of Christendom in their most alluring shapes. In this grave crisis in the far East their profession will watch for news of them with the greatest concern.

The Legality of Compulsory Vaccination for School Children.—After hearing argument as to the

merits of vaccination and as to the right of the Legislature and the Board of Education to make regulations requiring pupils in the public schools to be vaccinated, two learned and honored judges of the Court of Common Pleas of Philadelphia, after mature deliberation, in a suit by a citizen seeking to compel the admission of his unvaccinated child into school, have decided in favor of the legality of the law. This victory for preventive medicine is of no small import. It means that those who have studied the question of vaccination intelligently, including in the present instance Legislature, Board of Education, school principal, and justices at law, have been able to reach but one conclusion, namely, that the procedure is a beneficent one, whose enforcement is essential for the preservation of the health of the community, and that those who will not or cannot recognize the force of this proposition shall not be permitted to jeopardize the health and the happiness of those who seek the protection conferred by a simple and inoffensive device against what was at one time one of the most destructive diseases known to man.

Dr. John Ashhurst.—Philadelphia loses one of her best citizens and the medical profession one of its most eminent members in the death of Professor Ashhurst. He represented many things, both in his attainments and in his personality, which are not often found associated in such a high degree in one and the same individual. Dr. Ashhurst was both a surgeon and a scholar; both a scientist and a humanist, as well as a distinguished professor and a Christian gentleman. He was one of the rapidly diminishing group of really great doctors who found their earliest opportunities in the great Civil War, and in a peculiar and forceful way he represented all the honorable traditions and culture which we are apt to associate with the older generation. With all this he has died when little past his prime and while still, in the ordinary course, he might for many years have continued to stand in the foremost rank among the teachers of his day. As an author he had a high repute; as a teacher, a close following; as an operator, a large measure of success; and as a consultant, a universal respect. In numerous circles, both within and without the profession, his loss will be deplored, for he filled many stations and adorned them all. In these latter

days of shifting theory and exigent practice he stood for what was perennial and best in both the intellectual and the professional life, and he will long be remembered as an exemplar of the ideal which places the highest good in a man's career in the attainment of character rather than in the mere achievement of success.

The Question of Rapid Operating.—Several of our correspondents have taken exception to certain statements made in these columns with regard to this subject. The following letter seems to include most of the objections which are brought forward to the editorial just mentioned:

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

Perhaps you do not know yourself the immense influence you wield or you would not have written an editorial about "Rapid Operating Craze." You have given a strong weapon into the hands of the slow, slovenly, and incompetent. They refer to you as authority and claim perfect right to operate slowly and deliberately, keeping the patient under the influence of anesthetic for hours. There are a good many who operate who are not surgeons, they are simply *dissectors*; they cut and cut and cut without accomplishing anything. Many have no proper instruments. They do not know what they are going to do, and they are not prepared. They do not have the instruments, nor ligatures, nor needles, nor dressing. They are always looking around for something, and have to wait until it is found and sterilized, and thus operate for hours when they could do it in 10 or 15 minutes. The result, in short, is shock, heart clot, and septic infection. You certainly should know and have thought of this before. For to endorse slow and slovenly operations is wrong. What is necessary is to make the diagnosis beforehand, know what is going to be done, then have everything ready before the start; as soon as the patient is under chloroform operate quickly, do not cogitate so long or discuss what is best to be done, that ought to be worked out beforehand. When the first incision is made there ought to be quick and uninterrupted work, but by being quick is not said that any important detail should be neglected. You very correctly say that in trying to break a record, carelessness in controlling the blood supply or asepsis may cause trouble. This is perfectly right all will agree with you, as no matter how rapidly a surgeon operates he should be thorough and pay attention to the minutest detail.

I have seen a great many surgeons operate and the successful ones were always the men who operate quickly, the men who had a mechanical hand; who thought rapidly and met emergencies promptly; who would do what was to be done when something unexpected arose, before a slow operator would notice that there was anything out of the way. The surgeon who neglects thoroughness for speed is certainly not to be trusted as you say, but a surgeon who waits and is so thorough and so slow that the patient often dies on the table, or soon after, is also not to be trusted. What you want is the *greatest possible speed* with the most perfect thoroughness. I am sure you will agree with this. What induced me to write this communication is the enclosed slip taken from a secular paper, and is a copy of your editorial, and which shows the influence of your journal and the danger of the enunciating of such doctrines when the general public has access to them.

Yours truly,

J. H. CARSTENS.

Evidently many of our readers have misinterpreted entirely the intention of the original editorial—certainly many of the criticisms are not called for in answer to any statements which it contained. We had no excuse to offer, nor have we now, for those surgeons who are ignorant, not equipped with suitable instruments, and careless with regard to preparation for operation. We

fail to see in what way the statements which we made with regard to careful dissection and manipulation and thoroughness of antisepsis and hemostasis are an endorsement of slow and slovenly operations. We would by no means encourage unnecessary prolongation of operations, but we still hold that the operator who is striving to make a record for rapidity is unlikely to distinguish himself for carefulness or thoroughness in his work. We regret that it is possible for the public or members of our own profession to criticise certain dangerous tendencies, but the only way to overcome such tendencies is to recognize them clearly. The profession now generally admits that there was, a few years ago, a craze for the operation of ovariectomy, and that many women were unsexed by operators who were anxious to make records for the number of their operations and who were not entirely scrupulous as regards the cases in which they operated. No doubt there will always be some who will take greater pride in the number of their operations or the rapidity with which they are performed than on their judgment in the selection of the cases for operation and the results which they obtain. Probably our correspondent has not seen many of the really greatest surgeons operate or he would not say "the successful ones were always the men who operated quickly." Certainly a man who is extremely slow and clumsy can never hope to attain a very high position as a surgeon, but many of the most successful surgeons in this country and abroad are far from rapid operators. This is a matter of common remark, on the part of Americans who, for the first time, witness operations by some of the most eminent and celebrated German surgeons. We agree that the greatest possible speed consistent with perfect thoroughness is desirable, but the thoroughness should, in every case, be the first consideration.

The increase in deaths from cancer is receiving considerable attention both in this country and abroad. Statistics are presented by which it is shown that for the last two or three decades the fatalities from malignant growths have rapidly multiplied. Various scientific reasons have been advanced, and the State of New York has, for several years, made large appropriations to enable scientific men, selected for their special knowledge of the subject, to carry on research in this direction. This work is being done in one of the laboratories of the University of Buffalo, and its results will be eagerly awaited by the entire scientific world.

However, the discussions which have been held on the subject of late, have added considerable to the interest. It is questionable whether the number of malignant growths has actually increased to the extent frequently contended for it. Many diseases which are now properly classified in reliable death-records were formerly vaguely or indefinitely recorded. Undertakers or other laymen filed certificates of death in which any

cause of death was acceptable so long as it was a cause. It is, therefore, not surprising to find tumors, swellings, ulcers, chronic obstruction, swelling of glands, piles, hemorrhage, and other similar terms, gravely inserted as the cause of death, while other certificates contain still more Solomonic wisdom when the cause is given as "don't know." In view of this knowledge of the past, it is hardly fair to make a comparison with the present.

The American Medico-Psychological Association.

—At the recent annual meeting of this association, held in Richmond, Virginia, a committee was appointed to open communication with the American Medical Congress with a view of establishing relations with this latter organization. The American Medico-Psychological Association is composed, as is well known, of the leading medical superintendents of American hospitals for the insane, and this announcement will especially interest those members of the profession who seem to think that the asylum doctors are indifferent to an affiliation with the other representative medical societies. For ourselves we do not believe that feelings of indifference or estrangement exist, to any great extent, either within or without the asylums, and we welcome this announcement with pleasure. The asylum physicians have sometimes been taxed with being indifferent to the advancement of pure science within their own specialty; on the other side, they themselves have possibly felt that the profession at large was not sufficiently appreciative of the immense work they are doing in the practical care of the insane. We do not hesitate to say that the immense value of this work cannot be overestimated, and that it constitutes of necessity, and always will constitute, a distinct field of activity, which is just as much entitled to recognition as the rather more aggressive specialty of pathological anatomy. It is a practical clinical field of the widest scope and is quite distinct from the work of the laboratory. The trouble has been that these two departments of medical activity in this country have not always worked in complete unison, and this has evidently been largely due to the conditions under which the asylums pursue their work. Many of them, from the necessities of their environment, are not prepared to enter upon extensive pathologic projects, and it is unjust to expect them to do so. The fact that they have been subject to criticism for this has doubtless caused some resentment, but the recent move of the Medico-Psychological Association is a proof that the medical superintendents are desirous of coming into closer touch with the other medical bodies whose aims are more purely scientific. This is most satisfactory, and will doubtless be advantageous all round. There is ample evidence of a growing desire among asylum physicians to advance the cause of scientific psychiatry, while at the same time supporting the claims of their practical administrative work to a wider recognition. We be-

lieve that their affiliation with the Congress will be a step towards a better mutual understanding, and a more successful cultivation of the science of psychiatry in this country.

Pistols and Coffee for Doctors.—We have it on the authority of the *British Medical Journal* that a duel was recently fought by M. Pozzi, the distinguished French surgeon, and a Dr. Devillers, who is not so distinguished. We congratulate the principals (or shall we call them *primates*?) that they saved their honors out of the wreck. Unlike most French duels, the affair seems to have been a singularly bloody one, for M. Pozzi received a wound on the wrist, and we presume there was some hemorrhage from it. The *British Medical Journal* has evidently spent some midnight oil in looking up the literature of the subject, and rescues a number of medical duels from the oblivion of the past. The wit and humor of our English contemporaries do full justice to the gravity of the subject, but may possibly have the one evil effect of making other medical men feel like fighting duels and killing somebody. We know no good reason why doctors, any more than other folks, should not fight duels. If duels are to be fought, there are some special reasons why medical men should acquit themselves well in them. The natural humanity of physicians, for instance, would lead them to avoid making the pastime too dangerous. This seems to have been a motive with M. Pozzi and Dr. Devillers, and the fact that M. Pozzi was hurt was doubtless due to an accident. Our only suggestion is that if American physicians go into this business (either for fun or for advertisement) they should make it a point to fight only French duels. By observing this precaution, they might be able to enjoy the affair in the next morning's newspapers. Mr. Bob Acres thought that a proper distance to fight with swords was about forty yards, but the French evidently insist on a closer interview, else M. Pozzi certainly would not have been harmed. Perhaps the eye-glasses were not properly adjusted, and the combatants overstepped the bounds. We are told by the eminent historian, Robertson, that the wager of battle was one of the last vestiges of feudalism to be swept away, but Robertson was evidently in error so far as refers to M. Pozzi and Dr. Devillers.

The Nature and Origin of Carcinoma.—The fact that carcinoma is a progressively fatal and not in any sense a self-limited disease, ever undergoing spontaneous recovery, would seem to indicate that it cannot be included among parasitic diseases of vegetable origin, among the bacterial diseases. That it is infectious or capable of transmission seems almost demonstrated, but there is no agreement with regard to the identity of the hypothetic causative agent. It must not be forgotten here, as with the parasitic diseases of vegetable

origin, that certain conditions of the organism—pre-disposing etiologic influences—are primarily essential for inoculation to take place. There can be no doubt that heredity, age and traumatism exert an influence in this connection. The only successful means of treatment as yet known consists in early and complete excision; but it is, perhaps, not extravagant to hope that, once the exciting cause is isolated, a biologic antidote may be obtained. A good deal of activity in research in this connection has been manifested in recent years, and one should be prepared to learn soon of the discovery of the nature and origin of carcinoma. In a review of recent studies upon this subject, read before the annual meeting of the Maine Medical Association on June 14, Dr. J. Collins Warren was inclined to agree with the statement that carcinoma is on the increase. The disease, unlike tuberculosis, is not uniformly distributed over the surface of the earth, but is rather confined to certain tolerably well-defined regions. Even houses and streets have been described in which cases have been repeatedly observed. There are numerous facts that are strongly suggestive of the communicability of carcinoma, but the clinical evidence, though positive, is not abundant. All of the inoculation-experiments, however, have been wanting in the isolation of the assigned causative agent from the induced lesions.

Medical Sermonets, No. 20. Medicine and Character.—"So long as we live we are giving our solution to this problem, the problem of conduct, solving it equally by what we do and what we do not do, by our activities and our inhibitions." It is a tribute to the humanizing and ennobling influence of our profession that so few of its practitioners give a mean solution to this problem, a summing-up of whims and accidents; or the bad solution of selfishness, passion or vice; that with all the opportunities for mercenary quackery, so few are selfish; that with all the lack of appreciation and ingratitude of the public, so few become embittered; that with all the temptations to the drug habits, so few yield; of all the sacred trusts, so few are betrayed. We all have our responsibility in sustaining the high reputation for character which the medical profession has attained; we cannot afford to neglect the principles of the code of ethics, to be exceptions to the rule. It is often asserted that one of the most important functions of our literary colleges is the building-up of character, but our medical schools are not supposed to exert much influence in this direction. No doubt the teacher of medicine often loses sight of this greatest opportunity presented by his position; yet the medical school must develop character as well as give specialized knowledge and skill or it will fail to produce graduates who can solve the problems of professional as well as of personal conduct. The attempt to be amusing by telling loose stories in the lecture-room; the slightest neglect in demanding the most scrupulous care in the laboratory; disregard of the sacredness of the human body in the dissecting-room; the slightest lack of kindness and consideration in the clinic, say nothing of roughness and brutality,—all these things and many others apparently as trifling may have a lasting influence in the characters of the future physicians of America and the world.

Correspondence.

SIGNS OF TUBERCULOSIS.

By ANDREW B. EADIE, M.D.,
of Ithaca, N.Y.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

IN connection with Dr. Harrington's communication, entitled "An Early Sign of Tuberculosis," in the JOURNAL, April 28, I would like to call attention to certain anatomic or facial signs that I have been accustomed to note in tuberculous and nontuberculous constitutions. They were first pointed out to me about 12 years ago by an old physician whose observations, extending over many years, he asserted, confirmed their value. He said that when the superciliary ridge was prominent, especially between the eyebrows, and, as is usual in such conformations, was crossed by two well-marked, upright wrinkles extending upward at right angles to the line of the brows at their inner terminations, and the cheek-bones wide apart, that such people were very resistant to pulmonary tuberculosis, and if attacked by any pulmonary disease would make a valiant struggle, and in many instances would recover. On the contrary, where the space between the brows was flat, even depressed and smooth, and the cheek-bones not prominent, such persons were prone to contract consumption, and when attacked to succumb quickly. I have met with many apparent confirmations of the value of these observations.

QUACKERY IN TEXAS.

By JAMES HILL BALL, M.D.,
of San Antonio, Tex.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I HAVE, in common with the ethical men of the profession throughout the country, the greatest respect for the PHILADELPHIA MEDICAL JOURNAL's constant and enlightened devotion to the higher interests of medicine. In no particular of its editorial work and responsibility is this devotion more "steadfast in grave hope and errorless purpose" than it is when given to the struggling cause of medical legislation. The views on this vexed subject, expressed from time to time in your editorial columns, are always just and wholesome, and have a far-reaching effect on professional sentiment and conduct. Realizing these facts, I desire to call your attention to the maladministration of medicine in Texas, and to point out certain factors that have not only contributed to its degradation, but have triumphed over its downfall.

You have recently given some consideration to the state of public medicine in Puerto Rico and the Philippines, but I must tell you that in neither of these remote and half-civilized dependencies are the impositions on the established facts of medicine as glaring, the trespasses on its dignity and utility as a real science as outrageous, as they are at the present time in the Lone Star State. It is a well known fact, that in these semi-barbarous countries evils of the nature suggested grow out of what is unconscious in ignorance, and are therefore excusable errors, but in the United States they grow out of what is consciously malevolent in legislation, and are unpardonable faults, if they are not something worse. For this reason, I repeat that medicine in Texas is more prostituted, more completely under the malign influences of vicious legislation, than it is anywhere else in the world outside of wholly savage countries. The naked facts I have to

adduce in support of this statement will more than confirm it.

There is now established in San Antonio, Texas, by authority of the state legislature, what purports to be, and legally is, a school of medicine and surgery, the "New York Medical College of San Antonio." Any one who may desire to worship at the shrine thus reared to the twin deities of the medical Olympus, has only to qualify in the sum of \$50. Professional learning and experience, general culture, temperament and habits of life are things that count for nothing, in sympathy and advancement, with this so-called school, which has dispensed with the everlasting tedium, the burden and wearisomeness of the old methods of study, and inaugurated a short and easy road to the practice of medicine.

With an effrontery unparalleled in the history of similar frauds, the New York Medical College of San Antonio publicly declares its chartered rights, and assails common intelligence by advertising that it "will give thorough course and graduate on thorough examination *by mail*." The student's presence in the flesh is not a fateful necessity. The scholar does not have to go to school. The student does not have to study. His responsibility in the acquirement of a diploma begins and ends with the payment of \$50. The course is otherwise suited to his capacity and convenience. In a word, the school is an exquisitely conceived and executed mechanism for the automatic creation of doctors of medicine.

To test its actual workings, "for things seen are mightier than things heard," the local association of medical men last month found an ignorant negro laborer and matriculated him at this school. For *one hour* each day the storage battery of his mind was charged with a working (?) knowledge of the medical sciences. He was not required to read, dissect, work in laboratories, listen to lectures, or attend clinics. He was simply charged with knowledge by induction. This interesting process of intellectual saturation was continued, an hour daily, for the bewildering period of seventeen days. It was then declared that the undergraduate vessel was full, up to the brim and running over, and our negro protege received his diploma with the seal of the great State of Texas duly attached. This diploma places this laboring man on terms of equality with the most experienced and capable member of the profession, so far as the laws of Texas are concerned, and permits him, in defiance of public decency and morality, to practise his calling among the afflicted of mankind. These are not jokes. They are grim, stupefying facts.

Fourteen names are signed to this man's diploma, which is in the possession of the Western Texas Medical Association, and it is instructive to note the relationship which some of these names bear to science. Of the 14 professors, 12 are graduates of the New York Medical College of San Antonio, which has been in existence since about the first of December, 1899, nearly *five months*. The professor of anatomy, one of the 12 immortals, obtained his diploma after wrestling with the medical sciences for 12 days. But the greatest distinction has been achieved by the Forest family. Dr. J. D. Forest, the founder of the school and its chief inspiration, is professor of ophthalmology, which he spells after a fashion peculiarly his own. His younger brother is professor of surgery; his wife is professor of diseases of women; his son, a precocious youngster, 6 years old, is professor of diseases of children. The wind here is beautifully tempered to the —, but I must not be frivolous. The situation is too critical. Besides, comment of any kind is unnecessary. The case speaks for itself.

To pretend that this school is not a manifest fraud, dishonest in purpose, disgraceful in method, and infamous in its immediate effects and consequences, one must be agitated by the blinding influence wrought over common sense by election to the legislature, which is directly responsible for its existence and conduct.

And just here I desire to say, that the wish to be just and impartial will not permit me to sit in judgment on what the average member of our legislature does in the discharge of other public duties, but if he has ever done anything for the maintenance, progress, or defense of medicine, I have never been able to find it out. Whatever he may be in other directions, he is a dismal failure when it comes to the question of medical legislation. Here, at least, he blunders interminably. In the effects produced, he reminds one of Ruskin's Irish missal-painter, "who dressed his angel with no sense of failure, in happy complacency, and put red dots in the palms of each hand, and rounded the eyes into perfect circles, and left the mouth out altogether." But whether he is, like the missal-painter, innocent and ignorant, and helps to place laws on our statute books without consciousness of imperfection either in himself or in the laws of his creation, I am unable to say, though I have my suspicions.

What is your experience in dealing with this *average* member of the legislature? Have you ever reached the deep and hidden solitudes of his mind and conscience? Have you ever attempted to train his intelligence, to correct his public morals, and overcome his half-hundred prejudices? These are the things I desire to know—the things that it behooves the profession of Texas to find out.

The Effects of the Climate of Colorado on Sleep.

—J. T. Eskridge (*Denver Medical Times*, June, 1900) contributes a valuable article, analyzing the relation of the climate to sleep, in the acclimated and the unacclimated throughout the State of Colorado, summing up his report as follows: 1. Acclimated. (a) Healthy people of regular habits have continuous and refreshing sleep; in those of irregular habits sleep is more disturbed and depressed than at sea levels. Refreshment from good sleep is greater in Colorado than at lower altitudes, but slight disturbances affect sleep to greater degree than at sea levels; less time is required to be devoted to sleep in Colorado. (b) In people who are mentally overworked, sleep is broken, less refreshing and shorter than at low altitudes. Conditions that disturb the nervous system and circulation have greater effects in interfering with sleep in high than in low altitudes. (c) Persons of nervous tendencies do not sleep well unless they guard against taking too much physical exercise. (d) Neurasthenics are much troubled with disturbed rest unless they take an abundance of physical and mental rest, avoiding all things that disturb the heart and digestive organs. (e) The hysterical suffer great aggravation of the nervous state, the pulse often becomes greatly accelerated and insomnia intense. (f) The intemperate suffer greater nervous effects than exist at sea level; this refers to tobacco and coffee as well as to alcohol. (g) Tuberculous subjects sleep well, particularly if they avoid overexercise and as their nutrition improves. 2. The unacclimated. (a) The tourist who exercises freely suffers from disturbed sleep; those who take matters quietly until they become gradually accustomed to the atmospheric condition, sleep well. (b) The nervous subject is especially irritable and his sleep is disturbed by exercise and excitement; absolute quiet produces refreshing sleep. (c) The melancholic types of insanity temporarily improve in their capacity for sleep, but the maniac, and the paranoiac types have their sleep greatly disturbed. (d) Neurasthenics have their sleep disturbed by the Colorado climate. (e) In unacclimated tuberculous subjects sleep is worse unless precaution is taken to lessen the usual amount of exercise. (f) The climate of Colorado is the best means to overcome the insomnia of subjects from eastern cities and suffering from impaired nutrition produced by overwork and worry. [M.B.T.]

Special Article.

THE NAVAL HOSPITAL STEWARD.

By WILBUR F. THOMSON,

Hospital Steward, U. S. N.,

U. S. Naval Hospital, Pensacola, Fla.

FEW in the medical and pharmaceutical professions are familiar with the duties of the hospital steward in the United States Navy; nor do they, the pharmaceutical profession in particular, have any idea how little strictly pharmaceutical work is required of him; his duties are medico-clerical rather than pharmacal. Until recent years surgeons of the navy were permitted to have appointed whomever they wished as hospital stewards, then called apothecaries; and in consequence, not a few were appointed without regard to knowledge of medicine or pharmacy. But owing to the character of the duties being peculiar to the service and not to general pharmacy, they, after an enlistment, became quite as proficient as their brother apothecaries who possessed much wider experiences in the art of compounding medicines. It is not the intention to say that a thorough knowledge of pharmacy is not requisite for enlistment as hospital steward; for since the organization of the hospital corps, U. S. Navy, June, 1898, the examinations are more rigid and include more branches than examinations by State boards. A thorough knowledge of the following subjects is essential to pass a satisfactory examination for enlistment as naval hospital steward, viz: 1. General education: Arithmetic, orthography, writing (legible and grammatical), geography, and history of the United States. 2. Professional: *Materia Medica*—botanical names and the doses of drugs recognized by the pharmacopeia; pharmacy, the various pharmaceutical processes employed in the manufacture of officinal and official preparations, and the relative proportion of the more important drugs entering into their composition; chemistry—chemical symbols, the formulae of the more important official chemicals, and the reactions produced by combinations of chemicals; toxicology—symptoms, toxic doses and antidotes for poisons; recognition of crude drugs, making ordinary pharmaceutical preparations, compounding prescriptions, and criticising prescriptions incorrect by reason of pharmaceutical or chemical incompatibility; bandaging, minor surgery, application of dry and wet cups, application of splints, and the treatment of hemorrhage. Yet this presents but a foundation for the many duties and details learned only by actual experience in the service; and these duties, unless studied diligently and accurately, are mastered only after two or three years of service.

The work and study of the pharmacist in the average drug-store differs so widely from that of the naval hospital steward, that they can be compared only in a few respects. In the average drug store the pharmacist has the commercial side of the question to be dealt with; buying and selling, market quotations and fluctuations, price-cutting, ledgers of unpaid accounts, the cigar counter and soda fountain; the hospital steward has to contend with none of these. The average pharmacist employs his knowledge of pharmacy behind his prescription-case and in the manufacture of his own preparations; the hospital steward has but little compounding to do, medicines are supplied, in the most part, ready for dispensing, and most combinations are prescribed in pill or tablet form or in simple solution, and usually dispensed in doses as required. Bandaging, dressing wounds, drawing teeth, arresting hemorrhage or applying splints in the case of accident, assisting the surgeon in major operations, and during the absence of the surgeon, supplying aid and advice in cases of emergency, are a few of the duties of a naval hospital steward; in such events the average pharmacist recommends some physician or surgeon whose office is in the immediate vicinity. At naval hospitals the duties of the hospital steward are clerical, clerical and many; accurate records of the sick are kept by him, under the direction of the medical officer; records and reports concerning the hospital are made daily, weekly, quarterly, and yearly. Chemical examinations of food and water are often conducted by the hospital steward, under the supervision of the medical officer; the average pharmacist has his business

correspondence as the clerical part of his work, but is usually too much engrossed in the commercial side of his profession to devote any time to food and water analysis.

The salary received by a naval hospital steward probably exceeds that received by the average drug clerk considerably, but I think will fall below the income of the average proprietor. Owing to the superior advantage, I would say that a hospital stewardship in the United States Navy is, by far, better adapted to the study of medicine and surgery than to pharmacy; the advantages are direct instruction from the surgeons, men who are equalled only by the best in their profession; opportunities for closely observing the course of diseases under treatment, with a review of the cases from clinical notes; practical work in minor surgery, electrotherapeutics and hydrotherapeutics, microscopy, bacteriology, and chemistry.

To pharmacists whose ambition is to become more skilled as such, I would say that it was quite probable that their ambition would be realized more quickly behind the prescription case of the drug-store than in the service as a hospital steward. But if the pharmacist has an ambition to become a physician, the service is most admirably adapted for obtaining that degree. Of the three hospital stewards that have been stationed at this hospital during the past 15 years, two of them have become physicians, who are most creditable additions to the profession. It naturally occurs to one that hospital stewards who have received their education in the service would be most valuable as medical officers; yet very few receive commissions on account of being over the age which applicants are permitted to take the examination for appointment as assistant surgeons, that age being fixed at 30 years; and a hospital steward who enlists after the age of 25 cannot well qualify himself by the time he reaches the age of 30. If provision could be made, whereby qualified hospital stewards under the age of 35 would be permitted to be examined for appointments as assistant surgeons, those who were successful would remain in the service that educated them rather than to leave it to establish themselves in private practice.

Prior to the organization of the Naval Hospital Corps, naval hospital stewards could not hope for promotion, there being no higher grade at that time; since, however, the grade of pharmacist has been created, with 25 appointments, to which hospital stewards may aspire. While the pharmacist is a warrant officer, and enjoys all the privileges as such, he does not enjoy the privileges of the commissioned officer; and as far as rank is concerned, no further chance for promotion. Yet the appointment in this grade is most desirable, and is to be preferred to any of the positions that I can just now recall, in the practice of pharmacy; and I think that I am not presuming too much to say that there are many medical practitioners who would be glad to accept an appointment in that grade.

Impetigo Adenosa.—N. E. Aron-tam (*Medical Age*, June 10, 1900) describes 10 cases of a peculiar type of cutaneous affection to which, since he has failed to find it described or mentioned in any work on skin diseases, he gives the above title. He defines the disease as an acute contagious febrile affection characterized by the eruption of pustules and accompanied by enlargement of the lymphatic glands. It is contagious, since members of the same family were consecutively affected with it, also tenants in the same house and dwellings in the immediate vicinity were attacked. The cases observed were in children between 3 and 10 years of age. All of the patients complained bitterly of pain in the joints, suffered with vomiting of a protracted type and in many of the cases chill and convulsive movements existed. The exanthem appeared after 3 days as pustules the size of a pin-head only on the exposed portions of the body, the pustules were glistening, contained a yellow translucent fluid and were surrounded by an erythematous zone of bright scarlet. Simultaneous with the appearance of the eruption, the lymphatic glands of the groin, axilla, and neck began to enlarge, some even becoming as large as an egg. Fluctuation could never be detected. With the rupture of the pustule, febrile and constitutional phenomena declined. After rupture the contents of the pustules dried up and changed into crusts of a yellowish hue and encircled by a somewhat raised border of mahogany tint which in turn was surrounded by a deep red area. [M.B.T.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Medico-Chirurgical Hospital.—Dr. F. Savary Pearce has been elected clinical professor of nervous diseases.

St. Joseph's Hospital.—Dr. Melvin M. Franklin has been elected a visiting surgeon to St. Joseph's Hospital to succeed Dr. John S. Miller, resigned.

Pennsylvania Hospital.—A tent, 40x20 feet, has been erected on the hospital grounds, principally for cases of heat prostration, which do better in the tent than in the wards.

Deaths Before Coroner.—Coroner Dugan, of Philadelphia, investigated 29 deaths July 9. This unusually large list included victims of fireworks and heat and two drowning cases.

Homeopathic Board Files Report.—Reports received at the rooms of the State Medical Council in Harrisburg show that all the applicants recently examined by the Homeopathic Board in Philadelphia, except three, secured the necessary percentage to entitle them to certificates to practice medicine.

Living With a Broken Neck.—Lewis Bogel, a patient at the Samaritan Hospital, has a broken neck. His death is only a question of a few days. From his neck down he is paralyzed, and as good as dead, but his head is as clear and his mind as active as it ever was. He is fully conscious that he cannot recover, but does not bemoan his fate. Bogel fell from a tree July 4, at Wilkesbarre, a distance of 30 feet. He landed on his neck, breaking the fourth cervical vertebra.

Magee Pathological Institute, Mery Hospital, Pittsburg.—Applications will be received for the position of resident pathologist to this institution. The expenses of a postgraduate course in pathology and bacteriology at one of the prominent postgraduate schools will be borne by the hospital; the course to be taken prior to entering upon active work in the institute. Address all communications to Dr. John DeVinne Singley, 212 N. Highland Ave., E. E. Pittsburg.

Medical Department, National Guard of Pennsylvania.—A circular detailing the rules of the medical department of the National Guard has been issued by the Surgeon-General. The hospital corps of a regiment consists of a steward and one enlisted man from each company who must receive instruction from a medical officer for at least 8 hours each month. Applicants for the position of surgeon or assistant surgeon must have been in active practice for at least 4 years.

Smallpox in Philadelphia.—An entire block between North Fifth and Lawrence streets is under quarantine. The first case came from Virginia about 3 weeks ago, and the patient was sent to the Municipal Hospital with four others. Every possible precaution is taken to prevent the disease from spreading further among the prisoners. Each house is fumigated daily. Each person in the block is required to observe every sanitary regulation conducive to health. The prisoners are fed by the city.

The Children's Sanatorium at Red Bank, 6 miles below Philadelphia, on the Delaware River, was opened June 7, and since then 50,000 visits from Philadelphia have been made to the park on the two boats owned by the Institution. Last season 166,554 visits were made, and 35,000 took advantage of the baths. Boys over 10 years of age are excluded from the grounds. A midday lunch of soup and crackers is given to each child. The Institution is supported entirely by charity. Dr. Harry Wylie, of Philadelphia, is the visiting physician.

Residents at the Almshouse and House of Correction Appointed.—At the recent meeting of the Board of Charities and Correction the following physicians were elected to act as residents at the Almshouse and House of Correction: John E. Hume, W. L. Karcher, Henry G. Godfrey, Meyer S. Cohen, Edward J. Cunningham, William G.

Shields, Jr., Floyd S. Clarke, Albert P. Donahue, Clarence M. Harris, Edward L. Robinson, Howard L. Kaucher, Madison J. Keeney, C. M. Hosmer, Joseph F. De Silver, Angus MacOdrun, and C. A. Blayney.

Infants Starve in a Baby Farm.—Death by starvation was the verdict of the coroner's jury in the case of an infant who died July 5 at the baby farm of Henrietta Morris, Philadelphia. Mrs. Morris admitted that another baby was dead in the house and that a third is dying. She said that some of the children in her place were nameless and that she did not know where to find their parents. She said she got \$3 a week for the care of the babies. The Coroner severely censured the woman and said he would see that her license was revoked, her establishment closed, and the babies in the house returned to their parents or placed in proper institutions.

Slums Are Now Clean.—Weeks of persistent labor by the Bureau of Health of Philadelphia have made the slum section of the city as clean as time and labor can make it. Every year an inspection has been made, but this year greater attention has been paid to sanitation. Chief Good is guarding against contagious diseases that may be lurking in the alleys and cesspools. Many foreigners wondered how the force had learned that their premises were not clean, and viewed the work of the men with suspicion. Chief Good said: "Sewerage is poor downtown, especially in the wards fronting on the Delaware, between Chestnut street and Washington avenue. Conditions, however, are improving."

Vital Statistics of Philadelphia for the week ended July 7, 1900:

Total mortality	Cases.	544 Deaths.
Disease.		
Inflammation of appendix 6, bladder 2, brain 29, bronchi 8, kidneys 11, heart 1, lungs 27, pancreas 1, peritoneum 7, pleura 1, stomach and bowels 25		121
Cholera infantum		73
Inanition 24, debility 6, marasmus 30, anemia 1		61
Tuberculosis of lungs		35
Apoplexy 22, paralysis 9		31
Heart—disease of 24, fatty degeneration of 4, dropsy of 1		29
Convulsions		23
Casualties		18
Diphtheria	94	18
Carcinoma of face 1, peritoneum 1, stomach 3, uterus 3. Sarcoma—of neck 1. Tumor —ovarian 1, brain 1		11
Brain—congestion of 4, disease of 3, soften- ing of 3		10
Measles		10
Uremia 8, diabetes 2		10
Old age		9
Typhoid fever	25	8
Teething		6
Diarrhea 3, dysentery 1		7
Bright's disease		6
Sunstroke		5
Septicemia		4
Burns and scalds		4
Abscess of—peritoneum 1, lungs 1, back 1. Drowned		3
Suicide—cutting arteries 1, drowning 1, shooting 1		3
Syphilis		3
Searlet fever	11	2
Congestion of lungs 2, homicide 2, locomotor ataxia 2, rheumatism 2, suffocation 2, asthma 1, atheroma 1, cirrhosis of the liver 1, epilepsy 1, goiter 1, gangrene of foot 1, hemorrhage from stomach 1, ber- nial 1, indyosum 1, insanity 1, intussus- ception 1, pyemia 1, surgical shock 1, tetanus 1, ulceration of stomach 1, whoop- ing cough 1.		

Philadelphia Pediatric Society.—Tuesday, June 12. DR. JOSEPH SAILER, by invitation, presented a patient, a girl of 4 years, having a pulsating swelling in the region of the external occipital protuberance. The patient fell down stairs 5 months ago and no untoward result was noticed for 2 months, when strabismus appeared and there were attacks of vomiting with pain in the back of the head. Improvement followed treatment, but ataxia developed, which is so marked that the patient frequently falls when walking, and there is also incoordination in the arms. The tension of the

tumor is not increased by respiration. Deep palpation shows a ragged orifice with bony edges, fluctuation, thrill and a murmur, audible a short distance away from the head, are present and aspiration showed that the swelling contained blood. The diagnosis of **aneurysm** was therefore made. DR. ALFRED HAND, JR., reported several cases of so-called **glandular fever**, the group of symptoms, which were described by E. Pfeiffer, being fever of irregular type, and enlargement of the lymphatic glands beneath and posterior to the upper end of the sternomastoid muscle; the enlargement was so great in some cases as to cause a decided torticollis; suppuration occurred in no case, perhaps attributable to the use of 25% ichthyol ointment. The term glandular fever conveys the idea of a distinct disease and in view of the obscure and evidently varying etiology of the condition the term proposed by A. Muggia, acute cervical lymphadenitis, is considered better, at least until the specific nature is proved or disproved. DR. GRIFFITH reported groups of cases of **influenza**, some members of each group presenting the symptoms of glandular fever while others had only the usual symptoms of influenza; it is reasonable to suppose that the cause of the enlarged glands was the influenza-bacillus, the condition in these cases therefore being part of influenza and not a separate disease. DR. H. D. MARCUS read the notes of a case of **gravel**, there being recurring attacks of painful urination with the presence of uric-acid crystals in the urine. DR. W. R. NICHOLSON reported a case of **infection with the Bacillus pyocyaneus** in a newborn infant, the clinical diagnosis being *malaena neonatorum*. The literature of the subject was thoroughly reviewed. DR. C. A. E. CODMAN reported a case of **leukocythemia** in a boy and exhibited stained preparations of the blood.

NEW YORK.

German Hospital, Brooklyn.—Dr. William Moser has been appointed assistant visiting physician to the German Hospital where he was formerly pathologist.

Dr. Alexander J. C. Skene, the eminent physician and surgeon of Brooklyn, died July 4, aged 62. He was one of the foremost gynecologists of his day and his contributions to medical literature have been many and valuable.

Cornell University.—Dr. Abram Tucker Kerr, of Buffalo, a graduate of Cornell in the class of 1895, and of the Medical Department of the University of Buffalo in 1897, has been appointed assistant professor of anatomy at Cornell University.

A Large Heart.—At an autopsy in New York, July 7, over the body of an unidentified man, who was choked to death by a quid of tobacco, Dr. Hamilton Williams of the coroner's office discovered that the man had a heart weighing 36 ounces.

Milk Made Many Ill.—Six members of the family of Rev. Rosenson and others living near were made seriously ill recently by milk purchased at a grocery store. The first case examined by Dr. Still pointed strongly to arsenical poisoning. The milk has been sent to a laboratory to be analyzed.

Tenements Disinfected.—A thorough cleansing of the Italian quarter in New York began July 6. Chinatown will be disposed of later. This is the first time in 10 years that these districts have been thoroughly cleansed; then a yellow fever scare caused it. Dr. Blauvelt expects the work to be done each year hereafter. About 15,000 gallons of disinfectant were used the first day. It is said that the \$20,000 appropriated is not too large.

A Queer Occupation.—Biting off the heads of live snakes and rats for the entertainment of the public is the way in which William Gray, 12 years old, earns his livelihood. The lad was arraigned before Magistrate Voorhees in the Coney Island Police Court, July 5, and that is what he told the Court why he should not be committed as being without a visible means of support. His story was corroborated by the police. This boy was brought from Georgia early in the season as the chief attraction of a side show just off the Bowery.

Tried to Hypnotize a Bear.—It will no longer be the ambition of John Farrell to be an animal hypnotizer. At present he is in Fordham Hospital and the surgeons are consulting whether to amputate his hand or take off the arm at the elbow. He went to the park to show off his hypnotic powers and put his hand in the mouth of a large Polar bear, which failed to respond properly to Farrell's suggestions.

A Sick Man's Hard Luck.—Tatinia Berlingo, suffering from malaria, had an exciting trip to Bellevue Hospital in an ambulance with Sing Yung, a crazy Chinaman. Sing grabbed the Italian by the throat, and all the way to the hospital Dr. Crane and Berlingo were trying to keep him quiet. Berlingo was exhausted and had to be lifted out at the hospital while Sing was put in a straight jacket and taken to the pavilion for the insane.

New York Hospital Society.—In the report of the society of the New York Hospital it is stated that 62% of the patients in the wards of the several institutions under the control of the society received absolutely free treatment, and a large proportion of the remainder paid less than the actual cost of treatment. The total number of days of hospital treatment was 63,048, of which 75% were free. The treatment at the house of relief is entirely free and was maintained at a cost of \$38,905.33 for the year.

Quarantine Hospital Needed.—The *Buffalo Medical Journal* says that a detention hospital is very much needed in that place. Hundreds of sailors are arriving and departing daily from this port, and when one becomes suspected of smallpox or other contagious disease there is no place to assign him pending the development of the case, except to the pest-house. Recently the Health Commissioner, Dr. Wende, quarantined two vessels on account of smallpox suspects, much to the loss of the ships.

Barren Island Injunction.—An injunction has been granted by Justice Andrews of the Supreme Court to the Sanitary Utilization Company which runs the Barren Island garbage-plant, restraining the Board of Health from enforcing the act recently passed by the Legislature prohibiting the burning of garbage on Barren Island. In case the act is declared constitutional, crematories would have to be built by the city at a cost of not less than \$20,000,000. The complainants are real estate dealers who wish to enhance the value of property in the neighborhood of the island.

The Health Board of New York has been criticised severely for not ignoring anonymous communications. It is the habit of the board, a correspondent says, and correctly, to turn the unsigned complaints it receives over to Inspectors, who examine the property said to be in bad condition, and the result is that "in most cases the owners are ordered to make repairs under penalty of a fine." The *New York Times* fails to see any just grievance in this. If the Inspectors were accustomed to order repairs not required by law, that would be another matter; but no such charge is made. Any landlord can protect himself from such attacks simply by putting and keeping his premises in decent order. The *Times* thinks the Health Board is entirely justified in utilizing and even inviting anonymous complaints. The New York Association for Improving the Condition of the Poor has not hesitated openly to advertise its willingness to investigate unsigned denunciations of wrong committed by people who have more or less in their power the only persons to whom the existence of those wrongs is known.

Unregistered Physicians.—Justice McAdam holds that the New York County Medical Association is entitled to fines collected from physicians convicted of practising medicine without lawful registration. This decision was given in a suit brought by the Association against the city to recover a fine of \$50 collected from one Tito. The suit was a test case. Tito was arrested for practising medicine in the county of New York without lawful registration as a physician, tried and convicted, and was sentenced to pay a fine of \$50 or be imprisoned. He paid the fine, and the New York County Medical Association demanded it from the city under the authority of section 153 of chapter 398 of the laws of 1895. Justice McAdam says in his decision that since 1890 the plaintiff has been a duly incorporated society of the State, entitled to representation in the New York State Medical

Association, which was incorporated in 1884, and the State Association is the accredited society in the national body of physicians known as the American Medical Association. He says that the city contended that the act was for the exclusive benefit of three societies—the Medical, Homeopathic, and Eclectic—because they are named in certain prior acts. In regard to this contention Justice McAdam says:

"The construction contended for by the defendant would not effectively carry out the provisions of the act in regard to prosecuting offenders, for this is more surely accomplished by the liberal construction now given to it. The plaintiff discovered the offender, secured his conviction, the fine represents the fruit of its efforts, and there is no reason why it should not have the ransom."

NEW ENGLAND.

Must be Vaccinated.—On July 3 the Board of Health announced that all who had visited the home of Charles F. Sweetland, of Attleboro, the victim of smallpox, within a week, must be vaccinated. This will include about 60 persons. A hospital has been established at the Sweetland residence.

Law Regulating Sales of Ice.—Ice dealers throughout the State of Massachusetts must now retail ice in quantities as small as 5 cents' worth. Such is the requirements of the bill which passed through the last stages of enactment recently—short of the Governor's signature, which is not supposed to be in danger of being withheld.

"Divine Healer" Fined \$2,500.—Francis Truth, who advertised himself as a divine healer, has withdrawn his previous plea of not guilty, pleaded guilty and was fined \$2,500, which he paid. He pleaded guilty to seven indictments, accusing him of using the mails to furnish a scheme to defraud, which involved his divine healing methods, and on five charges he was fined the maximum penalty, \$500 each.

Murder by Faith-Cure.—Theodore Plausse, a 5-years-old boy of Webster, Mass., was burned to death last Sunday. The boy's screams attracted the attention of his grandfather, who was a faith-cure advocate. The latter, instead of attempting to extinguish the flames, fell on his knees and prayed. While his grandson's clothing was still blazing neighbors broke in and put out the fire, but too late to save the boy's life.

CHICAGO AND WESTERN STATES.

Ate Toadstools for Mushrooms.—An entire family of nine persons died July 9, near Calico Rock, Marion County, Ark., from eating poisonous toadstools, mistaking them for mushrooms.

University of Michigan.—The Board of Regents of the University of Michigan has conferred the degree of LL.D. upon Lewis S. F. Pilcher of Brooklyn, professor of surgery in Long Island Hospital and editor of the *Annals of Surgery*.

Hospital for South Chicago.—A building has been bought at Calumet Heights by the South Chicago Hospital Association, and the work of converting it into a hospital will begin immediately. It will have 2 wards, 6 large, double rooms, and will accommodate 25 patients.

Preferred Death to Ill-Health.—Two cases of suicide are reported from St. Louis, in persons who had been operated on at hospital and whose health had not been restored to their satisfaction. Joseph W. Griffin ended his life by a bullet at his home, while Elizabeth Trescher drank nitric acid at the hospital.

Refuse Thrown in River.—There is a general complaint that the river at Chicago is being used as a general dump for all sorts of rubbish. A great deal of filth goes in from the glucose works, gas works, and slaughter-houses. The harbor-masters have taken hold of the matter and guilty parties will be punished.

University of Illinois.—The property adjacent to the hospital building now occupied by the West Division High

School has been purchased by the Medical Department of the University for \$186,000. Dr. George P. Dreyer, associate professor of physiology in the Medical Department of Johns Hopkins University, has accepted the chair of physiology.

Scalp Almost Complete.—Ruby Richards, whose scalp was torn off about a year ago is still at the St. Louis City Hospital and is now possessed of almost an entire scalp. There is merely a small spot of the crown uncovered. The case is one which has required more continuous practice from the medical staff than any other in the hospital.

Playgrounds for Poor Children.—Dr. D. B. Steurer, president of the Cleveland Council, is interested in obtaining additional playgrounds for poor children. This is a question of the first importance from the hygienist's standpoint, and the medical profession of the city should stand ready to render any aid possible to the accomplishment of so necessary an object.

Scavengers Compelled to Obey Laws.—A new ordinance has been passed in San Francisco relative to the transportation of garbage. All garbage-wagons must be lined with zinc, sheet-iron, or other metallic substance, and must be water tight; and the covers must be of oiled canvas and be securely fastened, except when garbage is being put into the cart. Arrests have been made for violating this ordinance.

Street Noises.—The citizens of Chicago are trying to suppress street noises. An ordinance to this end has just been prepared which is directed against the following: Railroad companies, banana venders, vegetable peddlers, the iceman, the milkman who rattles his cane, the musical grippman, the umbrella tinker, the foghorn, the toy balloon man, river tugs, the early morning rooster, dogs that bark at the moon, braying donkeys, and cats that serenade.

The Ohio Hospital for Epileptics at Gallipolis receives \$480,400 from the State Legislature for 1900 and 1901. New land, including a large farm, will be purchased. The construction fund is \$125,000, of which \$85,000 is to be expended for a general hospital, \$50,000 for an Administration Building, and \$40,000 for two additional residence cottages for patients. A special appropriation had been made to enable the Pathologic Laboratory to participate in the pathologic exhibit of the American Medical Association, and provision has been made for the continuation of research work in this laboratory.

Plague Feared.—Health Commissioner Reynolds, of Chicago, received word from the National Board of Health, telling him to watch for travelers who come from Port Townsend and other Washington ports. This precaution is due to the arrival from the Orient of the steamer Queen Adelaide at Port Townsend in such a condition as to cause alarm among the health officials. The interior of the boat was in a filthy condition, and the Japanese physicians on board were unable to furnish a clean bill of health. The government's physicians feared bubonic plague and ordered the ship to be at once disinfected.

Kinyoun Purged of Contempt.—Federal Quarantine Officer Dr. J. J. Kinyoun, of San Francisco, has been discharged, being legally purged of contempt. It had been shown that the defendant had sent telegrams to the Federal quarantine officers at Eureka and San Diego suggesting precautionary measures against persons coming from the infected district. Dr. Kinyoun gave his opinion that vessels arriving at Eureka would be subject to quarantine restrictions by officers over whom the defendant had no control. He did not appear to have imposed as a condition for leaving San Francisco the procurement of health-certificates on the part of the passengers. There was no evidence tending to show that he violated the injunction or that he discriminated against the Chinese.

The Chinatown Nuisance.—Full justification is to be found in San Francisco's Chinatown, according to the *San Francisco Call*, for the removal of the Chinese from that locality, and should it ever become necessary there will not be lacking popular support to sustain it. At present there is a simpler remedy which is nothing more than the enforce-

ment of the health ordinances of the city. The Chinatown nuisance is made up of a host of violations of law. If the wealthy owners of property in the district are compelled to have their buildings put in proper repair much of the nuisance will be abated. Most of the buildings are overcrowded. If that is stopped a considerable number of the Chinese will have to move out of that district. The immediate work imposed upon the authorities is that of cleaning up the district as it stands and the enforcement within its limits of every ordinance of the city.

SOUTHERN STATES.

University of Maryland.—Dr. Chas. W. Mitchell has been elected to the chair of therapeutics in the University of Maryland, to succeed Dr. I. E. Atkinson, resigned.

Baltimore Medical College.—Dr. Wilmer Brinton has resigned the chair of obstetrics in the Baltimore Medical College. He is succeeded by Dr. J. M. H. Rowland.

Quarantine Changes.—The Governor has appointed Dr. J. N. Thomas to succeed Dr. C. P. Wilkinson as quarantine officer of Louisiana. His assistants will be Dr. T. Y. Aby at the quarantine station, and Dr. J. Hope Lamb at Port Eads.

Springfield Hospital.—Dr. Louise Holmes has been appointed assistant physician to the Springfield Hospital for the Insane at Sykesville, Md., and will have charge of the new group of buildings for female patients, which is now about ready to receive patients.

Smallpox Under Control.—Dr. W. C. Billings, of the United States Marine-Hospital Service, who has had charge of the smallpox hospital at Charlestown, W. Va., since its establishment has made the following report: Total number of patients received at hospital, 26; discharged, 16; number of suspects received, 55, all of whom will shortly be discharged unless a new case should develop among them.

A Pasteur Institute and Laboratory has been established in Atlanta and indorsed by the Medical Association of Georgia at a recent meeting. The Association also resolved to endeavor to secure through legislative enactment 50% of the tax on dogs for the support of the institution. The membership fee is \$10 and no dues. Dividends will be made and a discount of 50% given on all pathologic and bacteriologic work done in the laboratory.

\$15,000 for Blindness.—The famous damage case of John Marney, of Baltimore, against the Maryland Steel Company has been satisfied. Some years ago the case was tried and Marney got \$15,000 damages. The company vigorously fought the award and in every move Marney won. Interest has been charged on this amount since it was awarded. Marney lost his eyesight on account of an inexperienced man endeavoring to do the work of the regular man who was absent.

Butter-fat in Bottled Milk Diminished.—The mysterious diminution of butter-fat in the bottled milk which the United Milk Producers' Association is serving to Baltimore customers has caused the association officers to suspect that some of its drivers have been tampering with the milk. It has been found that in some instances milk which contained from 4.5 to 5.5% of butter-fat when it was bottled and sent out of the creamery only contained from 2.5 to 2.75% of butter-fat when the wagons were stopped on the street and sample bottles taken for analysis by the chemists, who reported that the milk had been tampered with and the association promptly offered a premium of \$500 to any person who would invent a seal to so fasten the caps of the milk bottles that they could not be opened and closed without the action being apparent.

CANADA.

The Ontario Medical Association met in Toronto June 6, 7. The discussions on Appendicitis, the Future of Therapy, Interprovincial Registration, and Army Medical Arrangements in South Africa were admirable, and the annual banquet was an enjoyable affair.

Canadian Medical Association.—The thirty-fourth annual meeting of the Canadian Medical Association, R. W. Powell, president, will be held in Ottawa, September 12-14.

MISCELLANY.

Report of Railroad Accidents.—According to the report of the Interstate Commerce Commission 7,123 persons were killed and 44,620 injured on the railroads during the year ending June 30. The number of passengers killed during the year was 239, and the injured, 3,442, or one passenger was killed for every 2,189,023 carried, and one injured for every 151,798 carried.

Obituary.—D. P. CALHOUN, of Jonesville, La., aged 81 years.—BENNETT F. BUSSEY, of Biggs, Cal., June 24, aged 92 years.—THOMAS P. EDWARDS, of Newark, N. J., July 4, aged 39 years.—CHARLES W. GELINEAU, of Indian Orchard, July 5, aged 56 years.—KING WYLLY, of Savannah, Ga., June 24, aged 59 years.—HOWARD P. BALLET, of Philadelphia, June 25, aged 23 years.—CHARLES F. MACDONALD, of Hamilton, Ont., July 8, aged 71 years.

Tuberculosis in Hawaiian Schools.—A resolution has been adopted by the board of education of Honolulu prohibiting any one from teaching in the public schools who is suffering from tuberculosis or any contagious or infectious disease, and also prohibiting children with such diseases from attending school. The mild climate of the islands has caused a great influx of consumptives recently and the authorities are alarmed for the safety of the native population.

The Plague in Brazil.—Eduardo Oldendorff, of Buenos Ayres, gives the following explanation of the bubonic plague scare in Brazil: The President of Brazil owes a visit of courtesy to the President of the Argentine Republic, which is long overdue. He is afraid to pay it, because if he leaves the country his enemies will start a revolution and place his rival in power, so he stays at home to keep the army and navy from deserting his cause. The existence of bubonic plague is not the first excuse he has invented to keep from paying the visit.

The Pan-American Exposition at Buffalo, N. Y., has entrusted the care of the department of ethnology and archeology to a practicing physician, Dr. A. L. Benedict. Many members of the profession are interested in the study of American ethnology and archeology and not a few have valuable collections of Indian relics and skeletons from Indian graves. Those not directly interested in this study could doubtless furnish the address of collectors. Dr. Benedict would be greatly obliged for information and for the loan of collections for the use of the department. Exhibits which represent study in some special line of American ethnology and archeology will be particularly suitable.

Woman's Sphere Again.—Regarding the alleged fatal wear and tear of a business life for women, especially for typewriters and stenographers, a St. Louis woman has collected some interesting statistics. She has found in one hospital, where the patients are mainly from well-to-do families, that of 165 women who have been admitted during the last year 95 are housewives, 14 are domestics, 3 are nurses, 6 teachers, 2 seamstresses, 1 a laundress, 2 worked in a factory, 4 are schoolgirls and 2 are stenographers. The remainder are women of leisure. In an institution where nervous diseases are a specialty there are 82 women patients. Of these 46 are housewives; 7 unmarried had been keeping their own homes; 5 are domestics and 15 are women of leisure. No stenographer had ever been an inmate there.

Victims of Lightning in the United States.—The Superintendent of the United States Weather Bureau states that the loss of life by lightning in this country last year was greater than in any year since statistics began to be collected. The number killed instantly, or suffered injuries from which death soon resulted, was 532; and 800 persons were injured, many of them suffering from physical shock, others from painful burns, and some from temporary paralysis of portions of the body. Paralysis of the arms or legs was the most common form of injury. The greatest number of fatalities, or 45%, occurred in the open; the next greatest number, or

34%, occurred in houses; 11% occurred under trees; and the least number, 9%, happened in barns. A number, mostly women, were killed while taking clothes from wire lines, or while near the lines during a thunderstorm.

Christian Science.—Recently the question arose in the Supreme Council of the Knights of Honor as to whether the lives of Christian Scientists, Faith Curists, etc., should be taken as risks. The supreme medical examiner said in his annual report, "We would not interfere with the religious bent of any Knight of Honor, but when a man professes to form a belief that tends, according to all scientific teaching, to shorten his life we must class him among the hazardous risks and decline to assume the risk." On the strength of this recommendation the committee proposed an amendment in reference to the noneligibility of members so as to exclude "one who avowedly professes to reject surgical or medical treatment for bodily injury or disease." This report was rejected by a vote of 64 to 13. However, the agitation was started and it is expected that other fraternal orders and regular insurance companies will take up the question. Inquiry of insurance companies has brought out the fact that there is in none of the application blanks of the companies any question which would bring out the information whether or not the applicant would avail himself of medical or surgical skill in case of illness or injury. The agents say that belief in Christian Science is a religious question and is not touched upon by the companies. Another way in which the question might be raised is by a Christian Science healer signing the death certificate of a beneficiary and the insurance company refusing to pay the policy on that ground.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended July 7, 1900:

Changes in the Medical Corps of the U. S. Army for the week ended July 7, 1900:

BRUHL, CHARLES E., acting assistant surgeon, will proceed to Cienfuegos, Cuba, for duty.

GIBSON, Major ROBERT J., surgeon, is granted leave for 1 month and 15 days.

LLOYD, CYRUS D., acting assistant surgeon, is granted leave for 1 month, on surgeon's certificate, with permission to visit Japan.

COOKE, ROBERT P., acting assistant surgeon, will proceed to Quemados, Cuba, and report to the commanding general, department of Havana and Pinar del Rio, for assignment to duty.

BROWN, CLARK L., hospital steward, is relieved from duty at the medical supply depot, Havana, Cuba, and will proceed to Quemados, Cuba, reporting to the chief surgeon, department of Havana and Pinar del Rio, for assignment to duty.

STEPHENSON, Major WILLIAM, surgeon, will proceed to Washington, D. C., and report to the Surgeon-General, U. S. Army, on business pertaining to the Medical Department of the Army.

STEPHENSON, Captain WILLIAM, assistant surgeon (now major, surgeon, U. S. Army), order of April 20 which relates to him is revoked, and he will proceed by transport via San Francisco, Cal., and Manila, P. I., to Taku, China, and report to Brigadier General Adna R. Chaffee, commanding the United States forces at or near that place, for assignment to duty.

FOGG, JOHN S., acting assistant surgeon, leave granted to him is extended 1 month, and he is granted permission to go beyond sea.

LORD, LESTER W., acting assistant surgeon, recently appointed, will report to the commanding officer of the troops stationed at Claveria, province of Cagayan, Luzon, for duty.

WHITTINGTON, Wm. L., acting assistant surgeon, now on sick report at first reserve hospital, Manila, P. I., is relieved from further duty in the department of the Visayas, and will report to the commanding officer, convalescent hospital, Corregidor Island, for temporary duty.

KELLY, WALTER K., acting assistant surgeon, now on duty at Ormoc, Leyte, is authorized to appear before the examining board in Manila, P. I., for examination for appointment as assistant surgeon, U. S. Army.

AMADOR, RAOUA, acting assistant surgeon, will proceed from New York City to Havana, Cuba, and report to the commanding general, division of Cuba, for assignment to duty.

HAYWARD, EDWIN P., acting assistant surgeon, will proceed from Nebraska City, Neb., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty in that department.

CORBUSSIER, HAROLD D., acting assistant surgeon, will proceed from Elmira, N. Y., to Manila, P. I., and report to the commanding general, division of the Philippines, for assignment to duty.

LATIMER, CHARLES H., acting assistant surgeon, will proceed from Washington, D. C., to Manila, P. I., and report to the commanding general, division of the Philippines, for assignment to duty.

Changes in the Medical Corps of the U. S. Navy, for the week ended July 7, 1900:

NORTON, O. D., surgeon, detached from the "Monadnock" and ordered to duty with marines at Taku, China.

WOODS, G. W., medical director, will be detached from Naval Hospital, New York, and placed on retired list August 24, 1900, having reached the age of 62 years.

COOK, F. C., passed assistant surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to the Naval Hospital, Washington, D. C.

LEYS, J. F., passed assistant surgeon, detached from the "Franklin" and ordered home and to wait orders.

Changes in the U. S. Marine-Hospital Service, for the week ended July 5, 1900:

STONER, G. W., surgeon, detailed as temporary medical purveyor during the absence on leave of medical purveyor.

CARTER, H. R., surgeon, upon being relieved from duty at Havana, Cuba, directed to report at Washington, D. C., for orders.

CARRINGTON, P. M., surgeon, granted leave of absence, on account of sickness, for 15 days from July 5.

MAGRUDER, G. M., surgeon, bureau order of June 15, directing Surgeon Magruder to proceed to Memphis, Tenn., and assume command of the service, revoked, and directed to proceed to New Orleans, La., and assume command of the service.

GEDDINGS, H. D., passed assistant surgeon, detailed as acting director of hygienic laboratory during absence of the director.

SMITH, A. C., passed assistant surgeon, directed to proceed to New York, N. Y., (Stapleton) and report to the medical officer in command for assignment to quarters. June 29. Granted extension of leave of absence for 8 days.

ROSENAU, M. J., passed assistant surgeon, upon completion of detail at International Congress of Medicine, Paris, France, to visit the Pasteur Institute and other laboratories for special temporary duty.

GARDNER, C. H., passed assistant surgeon, granted leave of absence for 21 days from July 19.

BLUE, Rupert, passed assistant surgeon, granted leave of absence for 15 days.

MATHEWSON, H. S., assistant surgeon, directed to proceed to Boston, Mass., and report to medical officer in command for duty and assignment to quarters.

HOBBS, W. C., assistant surgeon, directed to proceed to Honolulu, H. I., and report to Surgeon D. A. Carmichael for duty.

THORNBURY, F. J., assistant surgeon, relieved from duty at San Francisco, Cal., and directed to proceed to Port Townsend, Wash., for temporary duty. June 29.

HALLETT, E. B., acting assistant surgeon, granted leave of absence for 2 days from July 5.

MCDOWELL, W. F., hospital steward and chemist, relieved from duty at New York, N. Y., and directed to proceed to Havana, Cuba, and report to chief quarantine officer of Cuba for duty as hospital steward and chemist, and special disbursing officer.

KOLB, W. W., hospital steward, relieved from duty at Norfolk, Va., and directed to proceed to Savannah quarantine and report to the acting assistant surgeon in charge for duty and assignment to quarters.

SCOTT, E. B., hospital steward, upon being relieved from duty at Savannah quarantine, directed to proceed to Washington, D. C., and report at the bureau for duty.

foreign News and Notes.

GREAT BRITAIN.

The Malaria Conference which it was purposed to hold in Liverpool at the end of July has been postponed, the centenary celebration of the Royal College of Surgeons of England and other events in the medical and scientific world having been arranged for the same time.

Voluntary Notification of Phthisis.—The Plymouth Town Council has adopted a scheme for the voluntary notification of phthisis, by which medical practitioners will receive a fee of 2s. 6d. for each notification in the case of private patients and 1s. for the notification in parish or dispensary cases.

Westminster Hospital.—The clinical laboratories which have been added to Westminster Hospital were recently opened by Lord Lister in the presence of a large body of medical and scientific men. They have been added to enable a more scientific examination than was possible in the wards, and are equipped with all the latest apparatus.

Royal Victoria Infirmary.—On June 20, the foundation stone of the Royal Victoria Infirmary at Newcastle-on-Tyne was laid. Prof. Philipson in an address alluded to the building of the present infirmary 150 years ago, while mention was made of the fact that the new hospital would accommodate 400 patients, and have a home for 100 nurses.

The Model Milk Clauses came up for discussion again in connection with the Oldham Corporation Bill. An attempt was made to substitute for them the Leeds clauses which require the order of two justices for the inspection of a dairy outside the borough when it is suspected to be the source of disease, while the Model clauses, which were inserted, require one.

National Society for Employment of Epileptics. The annual meeting of the governors of this society was held recently in London. The medical staff stated that among the epileptic colonists at Chalfont great improvement had been noted in the majority of instances both as regards the general health and the disease. The Executive Committee gave a brief review of the progress of the colony since its commencement in 1894, and reports many thousands of epileptics who are in urgent need of such provision as the colony affords.

University of Cambridge.—Sir Michael Foster has been appointed the university member of the Council of the Jenner Institute of Preventive Medicine. Hubert Nicholls, of St. Johns College, has been admitted to the degree of Doctor of Medicine. During the academic year just ended 15 Doctors of Medicine, 1 Master of Surgery, 53 Bachelors of Medicine, and 65 Bachelors of Surgery took their degrees.

Diphtheria in Edinburgh.—An epidemic of diphtheria visited Edinburgh during the beginning of last month. Nearly 50 cases were reported, the cause of which the medical officer of health traced to the milk coming from a farm in the Liberton district. Since the supply has been stopped no cases have developed. None of the family of the dairyman was incapacitated from work, though all were suffering from sore throat.

Bar-Parlors and Tuberculosis.—Dr. J. Wheatley, medical officer of health of Blackburn, in his annual report states that no places, excluding the workrooms of some trades, are more favorable to the spread of tuberculosis than bar-parlors and other frequented rooms of public houses. He urges most scrupulous cleanliness in the management of these places. He also says that the birth-rate has been steadily declining since 1872, and was last year the lowest on record.

Unqualified Poison-Sellers.—A society of unqualified traders is trying to do away with some of the meager provisions existing for the protection of the public. This society is interested in the sale of certain poisonous preparations not intended for human use. They promise some sort of regulation. For instance, the dealer will be licensed and registered, and the articles are only to be sold in original packages as received from the makers, and labeled with the name of the vendors, the word poison, and the name of the active poisonous constituent. Particulars of each sale shall be registered.

Inoculation for Typhoid.—There has been general anxiety to learn the results of the tests made on the troops in South Africa. The Under-Secretary of War said that the information was being carefully compiled, but that so far the statistics were not enough to warrant conclusions. He further stated that no compulsion was used to induce soldiers to be inoculated, and that it was entirely optional with them. Members are anxious to learn whether there is any evidence of the protective character of the operation, whether it makes the disease run a milder course, and what proportion of those inoculated have recovered.

Typhoid Fever at Belfast.—For the week ended June 21, 50 cases of typhoid fever were reported in Belfast, Ireland. The Public Health Committee say that the cause is the bad water supply and claim that the catchment area at Stonyford is polluted. The commissioners obtained power to buy all farms the drainage of which might find its way into the Stonyford reservoir. The committee claims that this has never been acted upon. The places specially affected are on the direct supply from the Stonyford reservoir. Another view is that the disease is due to the soil being permeated with disease-germs due to the defective drainage of the jerry-built houses of Belfast.

The R. A. M. C. South African Fund.—A meeting of the General Committee of this Fund was held June 19. The total amount received was £2,266 8s. 4d. The *British Medical Journal* subscription resulted in the addition of £645 18s. 9d. to the fund. The report of the Executive Committee was presented by Surgeon-General Muir: 9,000 parcels had been sent to South Africa, containing upward of 100,000 articles. A vote of thanks to the ladies and others who had given assistance was moved by Major Wilson, who said that till the medical profession had made the Royal Army Medical Corps their own it could have been said that the corps belonged to nobody.

Food Preservative Investigation.—London is making a wry face over the disclosures following an investigation going on before the departmental committee appointed by the local government to inquire into food preservatives. It appears that nothing in recent years has caused so much trepidation among gourmets, for, from the humble smoked

herring to the luxurious foie gras, everything edible seems to be subject to a coloring process, either to hide its defects or to increase its charms to the eye of the inexperienced buyer. Dirty rice, for example, colored with coal-tar dye, was used to make what is called "egg powders," some of which have no association with the product of hens.

Proposed Exemption of Hospitals from Local Taxes.—The select committee of the House of Commons appointed to inquire into the proposed exemption of hospitals from local rates, met June 22 for the examination of witnesses. Mr. Burt said that the total amount of rates levied on the 77 scheduled medical hospitals in London, was £21,300 annually. He considered that those hospitals should be exempt that are carried on not for profit, but for the care of the sick, poor in mind or body, and maintained partly or wholly by voluntary contributions or endowments. The principal objection was that it was almost impossible to draw a line of exemption.

The Sale of Food and Drugs Act.—Mr. Walter Long, according to the *Lancet*, when questioned on the administration of the Sale of Food and Drugs Act of last year, said that he adhered to the view he had before expressed, that the main object of the Act was to ensure local action against adulteration, and the function of the Board of Agriculture was to exhaust every effort in urging, and, as far as they could, compelling, discharge of this duty before taking action themselves. Nothing could be more disastrous than for the central authority to be ready to do the work which rightly fell to the local authority. So far as he was aware the operation of the Act of last year had been most satisfactory.

Poisonous Sodium Phosphate.—Anxiety has been created recently by newspaper reports that a firm of chemists had informed their customers that a batch of effervescent sodium phosphate sent out by them contained arsenic. The makers of the effervescent preparation purchased the sodium phosphate in the ordinary physical condition from a well-known manufacturer of medical chemicals; it was then worked up into the effervescent form and distributed; after discovery of the poisonous nature of the preparation, warning was sent out; and a house which supplies retail chemists with proprietary articles notified these of the error. It is believed that most of the affected substance has been recovered.

To Investigate South African Hospitals.—In the House of Commons the names of the members of the committee appointed to investigate the South African hospital scandal have been announced as follows: Prof. D. J. Cunningham, Lord Justice Romer, and Dr. Church. Objections were made to the smallness of the number of the committee, and Mr. Balfour said that he would do his best to increase the membership of the committee to 5. A number of the members of the first Canadian contingent sent to South Africa sailed for home on the Allan Line steamer *Parisian* today. They complained greatly of the treatment they were subjected to in the field hospitals. Of the 1,150 Canadian troops, 800 were stricken down with enteric fever, mostly due to the putrid water of Paardeberg.

The St. Pancras Scandal.—The Lunacy Commission vote on June 22 gave an opportunity of calling attention to the gross scandal connected with relieving officers of the St. Pancras Board of Guardians in trafficking with the owners of private asylums to receive lunatics who should properly to have gone to the London County Council Asylums. Lord Russell said that this system of illegitimate commissions was not confined to St. Pancras, and that there had been cases in St. Matthew's, Bethnal Green. The relieving officers in St. Pancras, he said, had been in the habit of receiving 5s. for each medical examination, and the medical men who declined to make these payments were boycotted. This form of corruption, as well as the payments received from the owners of private asylums, the Lord Chief Justice said he had reason to fear was more widespread than was generally conceived.

Smallpox in Glasgow.—Smallpox has again visited Glasgow and although the epidemic as yet is not serious it continues to spread. Proximity of residence and a comparison of the dates of attack in one series of cases gave rise

to a suspicion of a common source of infection, and this most probably lay in an eating-house in the neighborhood. Inquiry elicited the fact that the wife of the eating-house keeper had recently died, there had been no medical attendant. Enough was elicited, however, to form a well-grounded suspicion of hemorrhagic smallpox, and the inquiry received its practical justification in the discovery that a daughter of this household was then recovering from an attack of the disease, so mild that not more than half a dozen spots could be detected. A circular has been issued to the medical practitioners of Glasgow urging them to encourage revaccination.

Sir William T. Gairdner, professor of medicine in the University of Glasgow, was entertained at a banquet, June 19, by his medical friends in the West of Scotland, on the occasion of his shortly leaving Glasgow to reside in Edinburgh. The customary loyal and patriotic toasts having been honored, Sheriff Barry proposed the toast of "The medical profession." He made a comparison between the three learned professions and considered that the world might be able to get on for a time without law, or even the Church, but not for a day without the medical profession. Sir William Turner in responding referred to a speech of Mr. Gladstone's in which the professions of medicine and politics were compared and the former considered superior. Principal Story proposed the toast of "The guest of the evening," and said that no better representative of all that was best in Scottish medical science than Sir William Gairdner had existed; that the University had lost an illustrious member.

The Granting of "Diplomas" to Midwives.—At the regular monthly meeting of the Medical Defence Union, the secretary read a draft letter concerning the granting of certificates to persons other than medical practitioners by certain associations and lying-in institutions, which certificates were taken by the holders as qualifying them to practise as midwives. The Council adopted the letter, and ordered it to be forwarded to the General Medical Council, with a recommendation from the Union to the following effect: That it is desirable, in the interests of the public, that medical practitioners, either individually or collectively by associations, should not be allowed to issue any document which in any way can be taken by the holder or the public as granting authority to practise, or which can be used to cover any practice of medicine, surgery, or midwifery, saving in the case of persons examined by duly appointed examining bodies under the supervision of the General Medical Council through their inspectors of examinations.

Medical Officers of School Boards.—The Swansea School Board, acting under the advice of its medical officers, has issued a leaflet of advice to parents. This school board has appointed two medical officers, Dr. Rhys Davies and Dr. E. Rice Morgan. These gentlemen make a quarterly inspection and report to the Board. The leaflet contains some excellent advice expressed in clear and simple language on various matters as to which parents are apt to sin rather from want of attention than from design. Thus under the head of fresh air it is pointed out that children spend, or ought to spend, nearly one-half of their time in bed, and that, therefore, the ventilation of their bedrooms is a matter of the greatest importance, and the value of the open fireplace and the inexpensive ventilating bar to the window is pointed out. The necessity for proper clothing of the arms and legs is insisted upon, as is also the importance of watertight boots. A few words are said as to guarding children from measles and whooping-cough, and it is pointed out that the earlier the age the more dangerous are these diseases to life. Perhaps the most valuable section of the leaflet is that on "general cleanliness." It is pointed out that clean children are liable to have lice in the hair, for if one child in a school has it others may become infected, and a systematic examination showed a very large proportion of all girls in the schools were infected. The leaflet also contains under this head observations on the necessity of attending to the teeth, a matter upon which it is usually more easy to influence parents, and upon the toilet of the nails.

The Liverpool School of Tropical Medicine.—On June 25 a meeting was held in Liverpool to consider what action should be taken to urge upon the Government the

necessity for the amelioration of the conditions of life in West Africa and other tropical countries, by improved sanitation, better water-supply, separation of the Europeans from the native races, and other means. Prof. Bryce said that the Liverpool Tropical School of Medicine had been founded only about a year ago. It was not founded more than a month before it sent out an expedition with Major Ross to the West Coast of Africa. Shortly afterwards another expedition was sent out, and was at present working in West Africa. Now the School was about to send a third, this time to South America. The German Government voted £6,000 to send out a commission to study tropical diseases, and especially malaria. No sooner had the United States got a footing in Cuba and the Philippines than they despatched expeditions. The expeditions the Liverpool Tropical School had sent out had directly shown the cause of malaria, and by that means had made it possible that certain measures could be taken to prevent the spread of the disease among Europeans.

CONTINENTAL EUROPE.

Medical Legislators.—Prof. Maragliano, of Genoa, and Prof. Golgi, of Pavia, have recently been elevated to the rank of Senator of the Kingdom. Professor Sanarelli, of Bologna, has also been elected one of the Deputies in the new Parliament.

The Balbi-Valier Prize.—The biennial prize of 3,000 lire (nearly £120), which was founded by Balbi Valier, has been awarded by the Venetian Institute of Sciences to Professor Graesi, of Rome, for his work on the mosquito and its relation to malaria.

Paris Supply of Water.—The supply of water from the springs of Long and Lunain, works for which have been in progress for many years, are now complete. The aqueduct is 100 kilometers in length, the quantity of water delivered is ample, and the works cost 24,000,000 f. By this means, even during great spells of heat, Paris will have a plentiful supply of drinking water, and the fears which have been entertained of a water famine during the Exhibition are shown to be unfounded.

Hospital Abuse in France.—The question of hospital abuse is apparently acutely felt in France by the general practitioner. In a recent letter to the *Concours Médical* attention was drawn to this growing evil and the disappearance of the system of free consultation advocated. In regard to hospitals this statement among others was made, that half the confinements in Paris are attended at the expense of the governing body of medical charities. Graduated payment for hospital treatment or paying hospitals and an agreement between the various members and branches of the medical profession were suggested.

Smallpox at Lyons.—The epidemic of smallpox at Lyons still continues. To lessen the necessity for the workman losing time by having to attend the vaccination station, public vaccinators are offering vaccination at the homes, but are met everywhere by refusals. Out of 700 men employed by one firm only 10 consented to be revaccinated and that only by a medical man specially supplied by the head of the firm. M. Rafin considers that the dry sweeping of staircases, which is a custom in Lyons, is a fruitful cause of the dissemination of infectious diseases, and M. Delore makes the same remark in regard to the custom of beating carpets in courtyards.

The Geographical Distribution of Goiter in France.—At a recent meeting of the Academy of Medicine, M. Poncet communicated the results of some statistics drawn up by M. L. Mayet relative to the distribution of goiter in various districts of France. The figures on which the statistics were based were taken from the returns furnished by provincial councils of the physical examination of recruits enrolled each year. The classification shows plainly that goiter is not distributed in a haphazard way, for the departments most affected are grouped in blocks occupying the regions of the Alps, the Pyrenees, the Central Plateau, the Jura, and the Vosges. The departments of the Aisne and the Orne alone show up as black spots in otherwise unaffected districts. M. Mayet has compared these figures with others for past periods, and concludes from these that the distri-

bution of goiter is still much the same as before, but that its amount has diminished, especially within the last 50 years. M. Mayet considers that probably the total number of goitrous people is between 375,000 and 400,000.

MISCELLANY.

Obituary.—PROF. THOMAS JONES, of Manchester, Chief Surgeon of the Welsh Army Hospital, died at Springfontein, in the Orange River Colony, June 18, aged 49. He was an eminent surgeon and a popular teacher, and was professor of surgery in Victoria University and surgeon to the Manchester Royal Infirmary.—HERBERT DAVIS, at Springfontein, June 15, aged 27.—GADET DE GASSICOURT, of Paris, aged 73.—PROF. MAXIMINO TEJNEIRO, of Santiago.—PROF. TEODARIO DE BONIS, of Naples, aged 53.—J. ICARD, editor of the *Lyon Médical*.—FRIEDRICH BROSN, of Dresden, aged 42.—SAMUEL HOPE, of Petworth, June 21, aged 56.—DR. KISLEY, of Hyde, aged 45.—JAMES LOGIE, of Woolwich, aged 43.—DR. EMBLETON, of Bournemouth.

Anti-Alcoholic Serum.—Dr. Crevally, of Sydney, New South Wales, has reported an experience with anti-alcoholic serum that throws doubt on the efficacy of the serum discovered by Sapellier, Thébault, and Broca. He began his experiments over two years ago at the Sydney Institute of Bacteriology. He subjected a calf to a long term of enforced drunkenness, obtained a serum from it and injected it into several confirmed drunkards. After two or three injections they gave up drinking, and the doctor thought that his discovery was established. He found, however, that after a week his subjects took to drink as hard as ever and came to the conclusion that their temporary cure was due to the imagination. His opinion was confirmed when they returned to him and, after he had injected clear water into them instead of the intoxicated calf-serum, they declared their repugnance for alcohol and kept sober for a few days.

An Important Discovery.—The Hygienic Institute of Würzburg University, Berlin, recently published the fact that Dr. Zierler had practically applied an important discovery made by the scientists of the University, and had succeeded in destroying bacteria in the teeth and jaws of living people by electric currents. Having killed the bacilli of the tooth-nerve decay, he applied the currents to other bacteria, and the success was complete. By careful controlling he proved that the organisms had been completely destroyed, while the nutritious substance to which they adhered had not been poisoned. The electric currents were introduced into carious roots of teeth just extracted, and they sterilized the whole root in each case. After repeating the experiment many times, he tried it upon patients, with great success. When the process is correctly applied it is absolutely painless, and the narrowest root-canals can be sterilized if the needle electrode can be introduced. He has also cured very severe cases of caries in the jawbone which seemed hopeless. He says that teeth that were considered lost under the old system may be saved by the application of this invention.

Undecorated Distinction.—It is related of Lord Bacon that in the earlier part of his career at the bar he was fain to ask for the honor of knighthood in order that he might no longer be in the anomalous position of being the only untitled member of his mess at Gray's Inn. Had he looked at the situation in the true light he would have seen that the very circumstance which he found so humiliating was for a man like him a higher distinction than any title. When Lord Castlereagh at the Congress of Vienna presented himself in a plain black coat amid the beribboned and bestarred throng of plenipotentiaries and diplomatic magnates, Prince Metternich said to him, "*Ma foi, Milord, c'est très distingué!*" A distinguished British officer disliked to have the initials of his order placed after his name, because, as he put it, "Everyone is a C.B. now." In France this is almost literally true as regards the Legion of Honor; it is difficult to find an undecorated individual, even if he is a doctor. There is a story that Professor Rostan once asked a patient admitted to his wards the name of the practitioner under whose care he had been before coming to hospital. The patient answered that it was a doctor with a decoration. To which Rostan replied: "If you had told me it was a doctor without one I might probably be able to identify him."—[*British Medical Journal*.]

2.—Ballantyne's second lecture on **antenatal diagnosis** is considered under the headings—(1) Maternal symptomatology; (2) Maternal physical examination; and (3) Physical examination of the fetus in utero. He considers the fact that the diagnosis of pregnancy is not easily made to be presumptive evidence that there is an abnormal pregnancy. Some of the symptomatologic deviations which are met with are, the occurrence of more or less regular and more or less sanguinolent discharges from the vagina. In the early months this may indicate a threatened abortion or a hydatid mole, and in the later months it may point to a low implantation of the placenta, or to premature separation of the same. It may also point to the existence of an antenatal morbid condition of the uterus itself, such as bicornate or septate organ, or to the presence of a tubal or tuboabdominal pregnancy. There may be deviations from the normal in the symptomatology of quickening. In cases of maternal malaria the mother has occasionally described attacks of fetal quivering and shaking, which seem to indicate that the fetus also suffered from malaria. Abnormalities in the degree and rate of abdominal enlargement, in the mammary sensations, the morning sickness, dysuria, headache, neuralgia, etc. In the maternal physical examination grave maternal cardiac disease will be undoubted warning that abortion, premature labor, or fetal death may be looked for and it may, especially when the maternal valvular lesion can be traced to acute rheumatism, mean that the infant will be born with a malformed heart. Pulmonary tuberculosis will often carry with it phthisis of the fetus, or tubercular changes in any of the organs or in the placenta. Morbid changes in the fetus may cause changes in the maternal organs which are capable of being recognized by the observer. Fetal death, for instance, may be followed by the disappearance of varicose veins, by shrinking of the thyroid enlargement, freer respiration, etc. Physical examination of the fetus in utero can hardly be separated from that of the mother's uterus and vagina, either in theory or practice. As a matter of fact, the two procedures are carried on simultaneously. [W.K.]

3.—Parsons and Littledale report 7 cases of **epidemic cerebrospinal meningitis**, 4 of whom recovered and 3 died. From these cases and the literature on the subject Parsons draws the following conclusions: Numerous outbreaks have occurred in America while England has escaped to a remarkable extent. The disease occurs chiefly in children and young adults, is most common in the spring, and the evidence tends strongly to show it is caused by the *Diplococcus intercellularis meningitidis*, which probably gains entrance by way of the nose. The onset is sudden and definite, with headache and often a chill; the temperature course is not constant; the head is retracted, chin pointed, and thighs flexed on the abdomen; Kernig's sign is usually present, and the kneejerk is diminished or absent; nasolabial herpes is common, likewise strabismus and double vision; albumin may or may not be in the urine. The prognosis is grave, but probably better for children than adults. Treatment consists of ice to the head and evaporating lotions, trional, bromids, and morphin. External rubbing with camphor liniment and alcohol relieves pain in the trunk and extremities. [A.B.C.]

4.—Uthoff and Maynard report a case of **hemorrhagic pancreatitis** occurring in a man of 77. The onset was sudden and characterized by pain in the abdomen, sickness, and collapse. Vomiting soon came on and occurred at intervals until death, which occurred 3 days after the onset. Each day of the illness was marked by a profound collapse from which the patient slowly recovered until the last, which ended in death. There was some distention of the abdominal wall. Necropsy showed the head of the pancreas to be the size of an orange. One large and numerous small hemorrhages had occurred in the substance of the organ. The capsule of the organ was thickened and tough. [A.B.C.]

5.—Jacobs reports a case of mumps in a boy of 10, complicated by acute pancreatitis. The mumps ran about the ordinary course, but with the subsidence of swelling of the parotids there appeared exquisite abdominal tenderness in the region of the pancreas. A distinct sausage shaped mass could be felt in this region. It corresponded in outline to the situation of the pancreas. Turpentine fomentations, calomel, Dover's powders, sodium bicarbonate, and a diaphoretic mixture relieved the condition, the tenderness and mass gradually disappearing. The boy made a good recovery. [A.B.C.]

6.—Ellerton reports a case of marked **emphysema following fracture of the sixth and seventh ribs**. There was cough and slight difficulty in breathing, but no hemoptysis or pneumothorax. With the exception of the forehead and legs the emphysematous crackling and percussion resonance were everywhere present, the examiner's fingers sinking three-quarters of an inch into the skin, and causing pain on pressure. The patient recovered from the immediate effects of the injury, but died several weeks later from general debility. [G.B.W.]

8.—Parker reports a case of double **harelip** in which in place of the usual probium and premaxilla found in these patients, a whitish globular tumor about half the size of the mouth presented. The skin and mucous membrane covering the growth were left in place while the tumor itself was removed. Three subsequent operations were necessary before a fairly satisfactory result was secured. The last operation was done to narrow the very broad nose. [G.B.W.]

1.—Mott in a lengthy, technical and valuable article discusses the nervous system. The **neuron theory** as formulated by Waldeyer some years ago is, with some modifications and additions, generally accepted today, despite the opposing views of some neurologists. Professor His showed that axis-cylinder, and other processes are really outgrowth from the cell protoplasm, and he believed that the apparent nervous network was really only an interlacing of the many cell processes. The author believes, however, that the neuron theory is not incompatible with the views of Held, namely, that the terminal arborization of the axis-cylinder of one neuron forms protoplasmic concrescences by fusion with the cell body and dendrites of another. This, of course, implies continuity of protoplasm of one neuron

with another, but trophically and genetically the two are independent. This independence is shown by secondary degeneration. Mott believes the "Nissl granules" seen in the cell protoplasm are formed by a death-change in the fluid plasma of the cell whereby the nucleoproteid substance contained in it is thrown down as a fine precipitate. That it is a death change is indicated by the cells taking a uniform stain under certain conditions, as after hyperpyrexia and coagulation necrosis resulting from cutting off of the blood-supply. The gray sympathetic fibers differ from the white fibers by the latter being supplied with a myelin sheath. The white fibers of the central nervous system differ from those of the peripheral system by not having the nucleated sheath of Schwann. Certain tracts of the central nervous system develop earlier than others. Different tracts in the posterior columns of the cord become myelinated at different periods, and it was owing to Flechsig's studies that those of endogenous origin were differentiated from those of exogenous origin. The practical outcome of this research was the modern idea of the **pathology of tabes**, for it was shown that the exogenous fibers were alone atrophied in tabes, while the endogenous fibers which have their trophic and genetic centers within the gray matter of the cord were spared. This is incompatible with the generally accepted view that the degeneration is caused by a sclerosis of the posterior columns; but it points to a nutritive failure in the trophic and genetic centers by which the outlying projections of the axis-cylinder processes undergo a regressive atrophy, the inverse of their development. There is a correlation between the functions of the systems, groups, and communities of the neurons and the myelination of their axons; thus in the brain and spinal cord of the fetus and the newborn child tracts of fibers are myelinated with definite regularity. The myelin sheath appears 3 or 4 months after the axis-cylinder process. The afferent fibers are myelinated before the efferent. The whole afferent tract, conducting tactile, articular, muscular, and visceral sensations by the posterior columns, fillet, thalamus, and corona radiata, are myelinated at birth. The cerebral cortex increases in richness of myelinated fibers up to the fortieth year and longer, but diminishes in old age. The myelin appears to be necessary for the functional activity of the nerve-tracts. [A.B.C.]

2.—Pavy has already called attention to two forms of **diabetes**: (1) The "alimentary" form, caused by failure of the system to properly assimilate the carbohydrates; and (2) the "composite" form, caused by the disintegration of proteid material, thus setting free in the circulation the sugar it contains. A certain small standard amount of sugar is found normally in the blood and urine, and this is not influenced by the ingestion of carbohydrate food. We no longer hear of excessive secretion of sugar by the liver as being the cause of diabetes. Everything points to the carbohydrates belonging to our food passing as sugar into the general circulation in diabetes in a manner that does not occur in health. In health this sugar should: (1) Be converted into fat before reaching the general circulation, and Pavy says this should occur mainly in the villi of the small intestines; or (2) part of it is disposed of by synthesis with nitrogenous substances to form proteids. The alimentary form of diabetes has to do with the failure of the carbohydrates to be properly assimilated—*i. e.*, converted into fat. The composite form of diabetes has to do with the synthetic compounds with nitrogen. If the ferric chlorid test gives no reaction it may be taken that thus far the case is only in the "alimentary" form. This may be corroborated by the cupric oxid reduction and by the polarimeter. The plan of treatment in the "alimentary" form is to restrict the diet of the patient, cutting down the starchy material in the diet till sugar disappears from the urine. The urine indicates when too much carbohydrates are being ingested, and, strange to say, the body weight indicates when too little is being ingested; for when there is no toleration of carbohydrates the restricted diet does not lead to loss in body weight; in fact, in this condition the patient often gains in weight, which may be fairly permanent. On the contrary, if there is toleration for carbohydrates and these are withheld, then there is a fall in weight. Thus the restoration of the normal assimilative power is the thing to be sought for. A sugar-free urine, on restricted diet, with a fall in weight augurs well. All sugar from the carbohydrate food should be assim-

lated before reaching the general circulation, as once there it will pass on to the urine. Everything tends to show that in diabetes the fault lies with the sugar being wrongly permitted to reach the general circulation as a consequence of the nonassimilation of the carbohydrate material. [A.B.C.]

3.—Blackmore calls attention to the way in which **plague** manifests itself as a rule in any place where it becomes epidemic. During the first year there are only a few cases and the disease apparently dies out. The following year it reappears and runs a distinctly longer and more virulent course and again apparently disappears. The next year it again appears and becomes epidemic. For 4 or 5 weeks the mortality is great, then it fluctuates. The exact means by which plague spreads is not definitely known. Rats doubtless convey it to other rats, but the author is of opinion that fleas and other vermin probably convey it to persons by inoculation. Rags probably serve as a good carrier. We know of no way of absolutely stamping out plague when it once gains a footing. The following precautions should be adopted to prevent its ingress: (1) A most careful search made for modified cases of plague for considerable time after it has apparently died out; (2) rigid inspection of vessels and passengers coming from infected places, even for months after; (3) disinfection of dirty rags and clothing coming from suspected places; (4) a sharp lookout kept for increased mortality among rats in seaport towns, and examination of their dead bodies for the plague-bacillus; (5) an attempt made to exterminate the vermin which might carry the germs; and (6) early inoculation of the people where plague has appeared among the rats. [A.B.C.]

4.—Croom reports a case of **chylous ascites** occurring in a woman of 39. She complained of swelling of the abdomen and gradually advancing weakness and emaciation. Up to 3 months previously she had enjoyed good health. She was the mother of 6 children, the youngest being 3½ years. The superficial veins were much distended, and the skin pigmented. A diagnosis of cancer of the omentum and mesentery was made. The abdominal cavity was aspirated and 380 ounces of a pale yellow pus-like fluid removed. This on microscopic and chemical examination showed 2% of fat, and debris composed mainly of leukocytes undergoing fatty degeneration. This relieved the patient for a short time, but subsequent tapping became necessary. The patient gradually became emaciated and died. Necropsy showed cancerous infiltration of the subpleural lymphatics, the stomach, small intestines, mesentery, and lymphatics along the principal bile-ducts. The lacteals especially were occluded. Though the receptaculum chyli and thoracic duct were free from disease a cancerous mass pressed upon the former. [A.B.C.]

5.—Palmer suggests **excision** of portions of **lung-tissue** in case of tuberculosis, basing his observations chiefly on anatomic considerations and the results of accidents affecting lung-tissue, together with the rare cases in which operation has been found necessary for other affections. He reports no personal experience, but reviews the literature of the subject thoroughly. [M.B.T.]

6.—Edgeworth describes 3 cases of **acroparesthesia**. They were all women between 40 and 50, engaged in earning their living by manual work, and otherwise in good health. The abnormal sensation complained of was a dead, tingling feeling in the hands and arms, which occurred either at night or on using the hands, or persistent though much worse on manual labor. In all three cases no objective signs of anything abnormal was discovered either when the patients were free from or suffering from the abnormal sensation. No symptom nor sign of hysteria was present. The pathology of acroparesthesia is unknown. According to Lereboullet the fault lies in the peripheral venous circulation which, by producing ischemia, or it may be passive hyperemia, results in serous infiltration of the terminal branches of the nerves. In some instances objective signs of vasomotor disturbance have been seen. The age and sex of the patient are predisposing factors. The following affections may be confounded with acroparesthesia: hysteria, peripheral neuritis, erythromelalgia, acrocyanosis, and arterial degeneration. The disease is difficult to treat. Bromids combined with small doses of nitroglycerin gave Edgeworth the best results. Two of the above cases were cured after six months. [A.B.C.]

7.—Burgs experimented with some 14 of the more ordi-

nary disinfectants to test their relative germicidal powers. The method to be pursued, briefly stated, is as follows: A pure culture of a germ having first been obtained, silk threads are impregnated with this and are afterwards exposed to the action of the disinfectant to be tested in a solution of known strength for a certain definite length of time, at the expiration of which they are removed, well washed in sterilized water, and placed under conditions known to be suitable for the growth and development of the germ in question. Should growth occur, it is evident that the disinfectant in this particular strength of solution has failed to destroy the vitality of the germ; in other words, that disinfection has not taken place, and *vice versa*. The specific germ selected for these experiments was the *Bacillus coli communis*. As a result of the experiments, which were very elaborate and required the use of some 2,000 test tubes, a valuable table was compiled. The following are some of the more ordinary substances tested: Bismid of mercury, perchlorid of mercury, chlorinated lime, formal aldehyde, lysol, carbolic acid. The author concludes that the bismid of mercury is the most efficacious, being especially better than the perchlorid, because it does not form an albuminate of mercury in the presence of albumin, as does the perchlorid. An idea of the relative values may be obtained from the following, in which the proportions are equally efficacious: Bismid, 1-5000; perchlorid, 1-2000; chlorinated lime, 1-100; formal aldehyde, 1-40; lysol, 1-20; carbolic acid, 1-20. In all of these the proportions given proved fatal to the germs within 5 minutes, and a slightly weaker mixture of each failed to kill. [A.B.C.]

8.—Thomson reports the case of a woman of 34 years, who, while suffering from typhoid fever, was attacked with acute glossitis. Some 30 days after the onset of the typhoid, during which time the patient gradually became worse, it was noticed that the left side of the tongue began to swell and become very red, firm and tender; 3 hours later the swelling had involved the right side. The great size of the tongue made it necessary to try to reduce it. Piercing with a grooved needle brought a little blood only. Death occurred soon after. Necropsy showed deep ulcers of the intestine with a perforation of the ileum, peritonitis, and ulcers on the dorsum of the tongue. The cause of the glossitis is a secondary local infection in most cases, in other cases it appears to be part of a general infection. [A.B.C.]

9.—Borland reports a case of imperforate hymen in a girl aged 13 years and 9 months. A large tumor rose above the pelvis reaching 2 inches above the umbilicus. The vulva was greatly bulged downward and the perineum distended. The vaginal orifice was completely occluded by a bluish membrane $2\frac{1}{2} \times 1\frac{1}{2}$ inches in size. This membrane was incised with a sterile knife for its whole length. The mucous membrane of the uterovaginal canal was found to be perfectly smooth and devoid of rugae. A large quantity of fluid was evacuated, and the recovery was uneventful. [W.K.]

10.—Danlop says thrombosis of the mesenteric vessels simulates very closely intestinal obstruction. Either the arteries or veins may be affected. If the arteries are thrombosed the symptoms are acute, if the veins, the symptoms are usually of the chronic form. In almost every case laparotomy for intestinal obstruction is performed. A case of a man of 51 is described. For 2 days he had suffered with acute pain in the hypogastrium, and vomiting. The pain was paroxysmal in character. The abdominal wall was flaccid, no abdominal tenderness nor distention. A quantity of bright red blood was passed by the rectum and soon after the patient died. Necropsy showed that 2 feet of the middle part of the ileum was congested, almost black, but not distended. The veins of the congested area were uniformly plugged with firm, dark-clotted blood. The corresponding arteries were healthy. No cause for the condition could be found. [A.B.C.]

11.—A boy of 16 who had passed through a moderately severe attack of typhoid fever suffered a relapse during convalescence; this seemed to be terminating very satisfactorily when, on the tenth day, he was taken with acute cutting pain in the abdomen; the abdominal muscles became tense, liver-dulness disappeared, and there was decided tenderness between the umbilicus and the anterior superior spine. On opening the abdomen in the median line, yellow serous fluid containing minute particles escaped, a perforation was found 6 inches to the cecal side of a Meckel's

diverticulum; it was small, round, and about 3 mm. in diameter. The bowel was carefully examined without any other perforation being discovered; the perforation was closed by Lembert sutures and a drainage tube was passed toward the pelvis, after irrigating with warm saline solution; the operation lasted 30 minutes and had no ill effects, except that there were attacks of vomiting for the first 36 hours; after this there was uninterrupted progress toward recovery. In a second case a boy of 18 had been ill 2 or 3 weeks with a moderately severe attack of typhoid fever. Pain in the abdomen after defecation was the first indication of perforation; there was general tenderness over the hypogastrium, absence of liver-dulness, the respirations were shallow and thoracic, and there was extensive tenderness 8 hours after the onset of the symptoms. After the preliminary shock had passed off, a median incision was made, light-yellow milky fluid escaped, the bowel was slightly distended and the peritoneal coat much injected. After examination of a considerable length of the ileum, a perforation with sloughing edges was found in the center of a thickened edematous patch; it was closed by interrupted Lembert sutures; the peritoneal cavity was irrigated with warm saline solution, and the operation terminated after 35 minutes. The patient was evidently collapsed, but rallied and seemed to be getting on well. The next day he became worse, and on the following day died, 43 hours after the operation. [M.B.T.]

6. Acute Gonorrheal Arthritis, etc., of the Left Shoulder, which Necessitated Operation and was followed by Rapid Recovery. J. COPLIN STINSON.
7. A Case of Hatpin in the Urethra. W. LAUNCELOT BROWN.

1.—Bates defines secondary cataract as a condition often following the removal of the lens, in which the pupil is veiled by a more or less opaque tissue. In probably 70% of all cataract extractions secondary cataract develops within 3 months after the operation. It may develop 12 months or even later after the operation. After carefully studying the cause of secondary cataract and its prevention by experimenting upon the eyes of many rabbits, Bates comes to the following conclusions: 1. Secondary cataract in the rabbit is composed of new connective tissue, usually, together with the folded posterior capsule of the lens. But the opacity of the structure occupying the pupillary area is due to the new connective tissue and not to the capsule. 2. The formation of secondary cataract in the rabbit begins with the accumulation in the anterior chamber of a coagulable fluid at the time of operation. Fibrin appears in the pupillary area from the coagulation of this fluid. Later, new connective tissue replaces the fibrin. 3. The prevention of secondary cataract in the rabbit may be secured by performing a quick operation, closing the scleral or corneal wound with sutures, and restoring the anterior chamber with normal salt-solution. A description of the operation follows; the author insists this must be performed quickly, keeping the anterior chamber filled with a normal salt-solution. [A.B.C.]

2.—Thompson reports a case of traumatic prostatitis occurring in a man of 51. He was struck forcibly in the perineum by the pommel of his saddle while riding a bicycle. The pain was so severe that he was scarcely able to get home and by the next day he was suffering from all the symptoms of acute prostatitis, frequent urination, tenesmus, hematuria, and painful defecation. An expectant plan of treatment was adopted and the acute symptoms grew markedly less in a few days, but the subacute condition lasted so long that he consulted another doctor who passed a sound with the result of starting up an acute exacerbation. He was seen by Thompson 7 weeks after the accident when the clin-

ical picture of acute prostatitis was still present. Under appropriate and conservative treatment the patient made a good recovery. [O.B.W.]

3.—Birchmore believes that with carefully and accurately adjusted instruments, and by proper staining methods, the **blood of individuals may be differentiated**; that by having a specimen of stained blood the expert may say whether another specimen was from the same individual. He is of opinion this would be of value in some medico-legal cases. [A.B.C.]

4.—Skinner reports a case of **typhoid fever** occurring in a woman of 52. The attack was preceded by nervous symptoms which led the author at first to diagnose the case as one of climacteric neurasthenia. The course of the disease differed from the usual typhoid attack in the following points: 1. The sudden rise of the temperature to the immediate neighborhood of 102° F., with its steadily sustained character and even course during the first six days, as contrasted with the ordinary morning and evening variation with a steady increase on successive days. 2. The persistent and obstinate constipation as contrasted with the diarrhea usually encountered. 3. The absence during the entire illness of bronchial symptoms and headache. 4. The atypical color of the stools, which were dark tan. 5. The acutely painful abdominal conditions, with the location of the point of greatest tenderness in the left iliac fossa. 6. The nausea and vomiting, steadily sustained early in attack; in typhoid we commonly observe anorexia, but rarely sustained vomiting and nausea. 7. The severely painful character of the myositis appearing late. 8. Absence of eruption. 9. The protracted fastigium, which lasted 7 weeks, the whole course of the excessive temperature extending over a period of 10 weeks. 10. The gratifying effect of dry heat of high degree upon the myositis, which ordinary means and pain-relieving drugs other than opium and morphin had failed to relieve. The patient recovered. [A.B.C.]

5.—Smith writes a lengthy and interesting article in which he condemns the present **abuse of medical charity**. City hospitals are doing a great work, but physicians are responsible for the fact that many persons receive free treatment at these institutions who are abundantly able to pay for services rendered them, and should be compelled to do so. Throughout the cities of the United States today probably fully one-third of the population are treated gratis. States are beginning to pass laws regulating dispensary practice, and physicians should encourage these measures. Salaried clergymen should pay the doctor's fee as does any other person. Club practice should be condemned, and physicians engaged in such practice should be excluded from medical societies. There should be a better understanding between the specialist and the general practitioner with reference to fees. The deliberate "beat" we always have with us. Physicians should arouse themselves and do something to prevent the indiscriminate giving of free medical service. [A.B.C.]

6.—In the case reported by Stinson the **arthritides** began towards the last of an acute **gonorrheal** prostatitis. The left shoulder-joint was affected. In a day the temperature rose to 102.5° F. and the pulse to 110, the pain was severe, even morphin in one-grain doses did not relieve it. In spite of local and general medication the symptoms grew worse, the patient becoming anemic, emaciated and careworn, so that opening of the joint was decided upon. The incision was made 2 inches in length downward from the coracoid process over the head of the humerus and about an ounce of turbid fluid escaped. The joint was irrigated with a 1:1000 mercuric chlorid solution and dried with mercuric chlorid gauze, followed by closure of all but half an inch of the wound, from which a small gauze drain protruded. A discharge which contained gonococci kept up for 2 weeks after the operation, during which time the arm was kept at absolute rest. When this discharge ceased, electricity, massage and passive movements were gradually begun and the patient in the course of 2 months had a perfectly cured arm. [O.B.W.]

7.—Brown reports a case of **hatpin in the urethra** of a man of 75. It was removed by an incision half an inch long at the base of the scrotum, through which the pin was easily grasped with a pair of forceps. The wound in the urethra was closed with silk sutures and it healed rapidly without continued catheterization. [O.B.W.]

Medical Record.

July 7, 1900. [Vol. 58, No. 1]

1. The Non-Suppurative Inflammations of the Brain, with Report of a Case of Hemorrhagic (Malarial?) Encephalitis. CHARLES L. DANA.
2. Preliminary Report on the Presence and Nature of Parasitic Amebas (Cancerameba Macroglossa) in the Epithelial Carcinomata. GUSTAV EISEN.
3. Three Cases of Vascular Tumor of the Orbit: Two Cured by Operation, One Apparently Cured Spontaneously. CHARLES STEDMAN BULL.
4. Fistula in Ano; its Relation to Phthisis. SAMUEL G. GANT.

1.—The authors divide **nonsuppurative inflammations of the brain** into the infectious encephalitis of infants, hemorrhagic polioencephalitis of adults, and hemorrhagic encephalitis due to some infection. The case reported occurred in an old man, and belonged to the third type. It was striking because these cases are usually seen in patients in early or middle life. There was no marked history of alcoholism, and no decided atheroma of the vessels. He had malarial infection, and examination of his blood at the time of observation showed the presence of plasmodia, and it was thought that the malaria acting upon bloodvessels which had been weakened by the use of alcohol led to the condition which caused his death. He was seen in a semiconscious condition. The most striking signs were paralysis of the tongue and lips. He had also almost complete paralysis of the left side. His hemiplegia improved somewhat, but he died 3 weeks after admission. The autopsy showed in the right hemisphere capillary hemorrhages and softening in the lower portion of the posterior central convolution, and in the anterior part of the marginal gyrus. There were 2 or 3 small lesions in the centrum ovale and some small foci in the spinal cord. The microscopic examination showed a hemorrhagic focus with some inflammatory reaction and epithelioid proliferation at the place described, with a more recent foci in the medulla and spinal cord. The microscopic examination is reported in full. Although malaria does not tend to produce reactive changes in the brain-tissue it is considered probable that alcohol, as in this case, might have produced the changes. The diagnosis of **hemorrhagic encephalitis** is chiefly from acute meningitis and ordinary cerebral hemorrhage. It differs from meningitis in the absence of stiff neck, small pupils, general rigidity, and twitching. From hemorrhage or thrombosis it differs in the presence of severe cerebral irritation persisting for some days before paralysis occurs, and there is usually also the story of some recent infection. The absence of leukocytosis may be of some aid in distinguishing the condition from suppurative processes. It is important to recognize hemorrhagic encephalitis, because some cases are curable. [D.L.E.]

2.—The summary of Eisen's results are as follows: First, he finds a **parasitic ameba in practically all epithelial carcinomas**. The reason that earlier researches and those of others have failed is, he believes, that the tissues were not properly fixed. The tissue should be fixed at once, as soon as it is removed from the growth and while yet at practically body-temperature. He uses a solution containing potassium bichromate, 3 parts; glacial acetic acid, 5 parts; water, 100 parts; fix for about 12 hours, then wash in running water for about 12 hours, and then harden in alcohol from 30% upward. He embeds in paraffin and stains with eosin and methylene-blue. He believes that these so-called canceramebas cause the characteristic appearance of the cell-nests. The amebas occupy the center, and the cells surrounding them in their effort to overcome them, form nests. The amebas are said to propagate by spores and by amitotic division. They are readily distinguished by their large size, frequently reaching 30μ. They are acutely sensitive to cold, and slight reduction of the temperature will cause them to contract and be much distorted. This suggests the possibility of successfully treating carcinomas by freezing. Eisen thinks that the bodies which he describes are the cause of the peculiar structure of cancer, and probably the cause of the affection itself. [D.L.E.]

3.—Bull reports 3 cases of **cavernoangioma of the orbit**; in one case spontaneous recovery apparently resulted; in another case electrolysis was first repeatedly but

unsuccessfully tried, and then the growth was removed by 2 operations at intervals of about 2 months; a third growth was also removed by operation. [M.B.T.]

4.—Gant draws the following conclusions as to the **relation between fistula in ano and phthisis**: Tuberculous fistula is usually secondary to tuberculous disease of the lungs; but the latter is rarely, if ever, secondary to fistula either before or after operation. When the patient's general condition will permit we should operate on all fistulas irrespective of the kind. We should not refuse to operate on persons suffering from a mild form of phthisis, nor on those who give a family history of tuberculosis. If we arrest one destructive process, nature is all the more capable of dealing with the other. Patients operated upon for tuberculous fistula and those nontuberculous but complicated by phthisis, who rapidly decline and die, do so as the result of an inflammation of the lungs induced by the anesthetic, especially ether. Such accidents have not followed any of the operations which Gant has made under local anesthesia. We are justified in discarding the teachings of writers who believe that the cure of a fistula will result in a development of phthisis. [M.B.T.]

Medical News.

July 7, 1900. [Vol. lxxvii, No. 1.]

1. The Hospital Governor and His Staff; Being a Glance at the Personnel of a Modern Hospital and a Plea for a Permanent Resident Staff. THOMAS J. HILLIS.
2. The Treatment of Tetanus. ALEXANDER LAMBERT.
3. The Immunizing Cure of Hay Fever. H. HOLBROOK CURTIS.
4. Significance of the Stool in Infantile Diarrheas. WM. EDGAR DARNALL.
5. Exstrophy of the Bladder Combined with Epispadias. W. B. YOUNG.

2.—Lambert gives a critical discussion of the evidence regarding the utility of **tetanus antitoxin** in the treatment of the disease. He calls attention first to the fact that in human beings, a mixed infection almost invariably occurs, and that the constitution of the tetanus toxin is still unknown. In general, it is desirable to use certain special antitoxins on wounds that may possibly be infected with the tetanus spores. Among these are a mixture of bichlorid, carbolic and hydrochloric acid, solutions of silver nitrate, solutions of iodine, formalin, etc. It is particularly important to remove all dirt from the wounds and this should be done at once, particularly in wounds the result of discharge of blank cartridges. Internally, physiologic antidotes, such as chloral, the best, or morphia either alone or combined with antimony, should be employed. A chemical antidote consists in the antitoxic serum. This is valuable in proportion to the shortness of the interval that has elapsed between its administration and infection. Statistics apparently show that the acute cases are not greatly improved by the administration of the antitoxin, but that in the chronic cases the percentage of deaths is materially reduced, from 40 to 16. This is, of course, when the antitoxin is not given until the symptoms develop. Bazy, who has adopted the plan of inoculating immediately all patients having wounds that might have been infected with tetanus, with 10 ccm. of tetanus antitoxin, has practically eliminated the disease from his clinic. Even intracerebral injection does not appear to be of any particular value. Nearly 88% of the acute cases died, which is just about the hospital statistics, and about 27% of the chronic cases. It has been shown that when the upper part of the spinal cord is involved in the disease, intracerebral inoculations are valueless. [Injection through a lumbar puncture has recently been tried with asserted good results. J.S.]

3.—The idea has occurred to Curtis of **immunizing patients** suffering from various forms of acute coryza produced by certain specific irritants. This was apparently suggested to him by the fact that two girls who were subject to ipecac cold and who were employed in a drug-store, could acquire a temporary tolerance for the drug by taking internally doses of the tincture or sirup for several days before the exposure. He, therefore, employed hypodermic injections of the watery extracts of flowers, upon a lady who was so susceptible that she could not pass a

florist's shop without having a very severe attack. Immunization was tried first for roses, and the acquired tolerance for these; then for various other flowers, and she gradually became able to endure all kinds. Curtis has also experimented upon cases of hay fever with the extract of ragweed, goldenrod, and lily of the valley. The results were good. He calls attention to the fact that the disease he has treated in this manner is really ragweed-coryza. He requests others to perform similar experiments in order that the true value of the method may be determined. [J.S.]

4.—Darnall describes the different types of bowel movements that occur in **infantile diarrheas**. The dirty lead-colored stool indicates infected masses of imperfectly digested food; the green stool is acid in reaction and indicates an excess of carbohydrates in the food; the thin watery stool containing small specks of light-pear-green color is intensely poisonous and occurs in the later stages of marasmus. Mucus indicates an inflammatory condition. If from the upper portion of the small intestine, it may be bile-stained; if from the colon, it is white. White or gray-white stools are composed largely of fat. The first step in the treatment of these conditions is to stop food for a day or two, using sterile water to allay the thirst, then evacuation by castor oil and aromatic sirup of rhubarb, followed by antiseptic doses of calomel given in tenths of a grain with $\frac{1}{4}$ grain doses of salol. If the stools are serous, Dover's powder may be employed. In case of profound exhaustion, stimulation either by brandy or by a mixture of morphia and strychnia may be employed. Hot applications over the abdomen often relieve the pain. If there is much mucus, bismuth with some aromatic substance may be employed. The most difficult part of the treatment is the adjustment of the diet. The proprietary foods are usually unsatisfactory. Modified milk, however, is both scientific and usually satisfactory. At first it is necessary to start with low proteids and the mixture should be pasteurized. Later, the proteids may be increased, to be decreased the moment curds appear. It is really not very difficult to have the milk modified at home. [J.S.]

5.—Young reports a case of **exstrophy of the bladder** combined with **epispadias**, in a patient who was a double cryptorchid. There was continual dribbling of the urine which, however, did not cause any excoriation, and the child was otherwise in perfect health. The parents refused operation. [J.S.]

1. Remarks on the Surgery of Uterine Fibroids, with Special Reference to the Importance of Early Removal in the Young. MAURICE H. RICHARDSON.
2. The Use of the Angiotribe. F. H. DAVENPORT.
3. A Case of Morbid Fear. J. W. COURTNEY.
4. Colostomy for Obstruction Due to Malignant Disease. J. B. BLAKE.

1.—Richardson regards the **early removal of uterine fibroids** as an exceedingly desirable procedure especially in the young, as it preserves the sex and does not destroy the power of bearing children and of enjoying life, as does the hysterectomy that will be necessary at a later stage of growth of the fibroid. A small fibroid may at any time cause a hemorrhage that will threaten life. If extramural, with a long pedicle, the pedicle may become twisted. Among the insidious complications must be mentioned the gradual effect of pressure upon the ureters and consequent hydronephrosis. When hysterectomy is necessary, however, he believes one important source of sepsis, that of cutting across the uterine canal, can be obviated by the use of the cautery. [W.K.]

2.—Davenport believes that the **angiotribe** is a safe and efficient means of controlling hemorrhage, renders the operation easier for the operator and more comfortable for the patient, that it is distinctly an advance and that it has come to stay. In vaginal hysterectomy in which the use of this instrument seems peculiarly indicated, his mode of procedure is as follows: Having seized the cervix with the vulsellum he divides the tissues in the posterior culdesac at the junction of the vaginal wall with the cervix, with the Paquelin cautery heated to a red heat. The point of the blade is kept close to the tissues and the whole breadth of the culdesac is

divided. The same is done on the anterior surface of the cervix, and the vagina is divided in the lateral culdesacs as well, but to a moderate depth only. The tissues are then pushed up front and back with the fingers, separating the attachments between the uterus, and bladder and rectum until the peritoneum is reached. If there are no adhesions and the uterus is small, the peritoneum is then opened and the anterior and posterior surfaces of the uterus freed. The blades of the angiotribe are then introduced on the left side under the guidance of the fingers, including as much of the broad ligament as they will grasp, close to the uterus. Care should be taken that the ends of the blade do not include bowel or omentum. The blades are then screwed together tightly, and the clamp allowed to remain for two minutes. The tissues are then divided on the uterine side, leaving a little margin of tissue on the outside of the clamp. When the clamp is carefully removed the edges of the broad ligament will be seen to be a flat ribbon as thin as paper, which is completely dry. The same is then done on the other side. If the uterus is small the fundus may be turned out anteriorly, and the upper part of one broad ligament, including the tube and round ligament and the ovarian artery, clamped from above, compressed for two minutes, then severed, the same done on the other side and the uterus removed. In case of a large uterus, after the uterine arteries have been compressed, the uterus may be bisected and each half removed separately. A plug of gauze is then inserted between the stumps of the broad ligaments and the operation is complete. [W.K.]

3.—Courtney reports the case of a stenographer, 22 years of age, who, at the death of her father, 7 years before, had suffered severe **emotional disturbance**. Subsequently, two other deaths occurred in her family, and she herself acquired a dread of dying. Frequently she had visions in which she was in the death-agony and was surrounded by her friends. There was a very pronounced neurpathic ancestry as well as cases of mental derangement in her family. Physically, aside from slight anemia, her condition was good, and she was able to perform her work satisfactorily. Courtney prescribed iron, forced feeding, and moderate exercise. This at first seemed to exaggerate the condition, but in the course of 3 months she had gained 16 pounds. A sort of pseudohypnosis was then employed, and by means of suggestion during this state her mental condition was changed to one of surprise at living. Subsequently, some mental gymnastics—that is, memorizing prose and poetic passages—were employed, and she appeared to recover completely. [J.S.]

4.—A cachectic, poorly nourished woman of 50 had had but 6 bowel movements in 5 weeks, her abdomen was distended and tympanitic except in the right iliac region. Rectal examination showed a hard, nodular, immovable tumor. Left **inguinal colostomy** was performed with slight relief and death followed 4 days later. At the necropsy carcinoma of the bladder and vagina extending to neighboring organs was found, with metastases in the retroperitoneal, bronchial, and mediastinal lymph-glands. The obstruction was located at the ileocecal valve. Considering the fact that obstruction may exist in the right as well as the left inguinal regions Blake suggests the possible desirability of a median exploratory incision to determine the site of obstruction in such cases before performing colostomy. [M.B.T.]

BOGUE, W. H. TOLD, G. LENNOX CURTIS, RHEIN, HENRY D. HATCH, JOHN S. MARSHALL, JAS. TRUMAN, A. E. BALDWIN, W. B. HILL, WILBUR F. LITCH, R. R. ANDREWS, ALICE STEEVES and E. S. TALBOT.

1.—Patton discusses **paroxysmal tachycardia** and reports 3 cases. A woman of 60 was under observation for 3 months, during which period the attacks became of longer duration and left her weaker and with increasing dilation of the heart. During her last attack the pulse-rate was 210, and dyspnea, cyanosis and death eventually resulted. In the case of a woman of 57 with moderate arteriosclerosis tachycardia, with a pulse-rate of over 200 per minute followed angina pectoris, and death resulted in about 10 days. A man of 50 had tachycardia with a pulse-rate of 260 per minute coming on during recovery from typhoid fever. Recovery and subsequent good health followed. Patton finds nothing definite with regard to the morbid anatomy of this affection; the prognosis is unfavorable in recurrent cases; there are no specific indications as to treatment. Diet and exercise should be adjusted; sources of irritation should be avoided. [M.B.T.]

2.—The following conclusions are drawn from **experimental and clinical study**: The route through the sixth cervical space to the **subarachnoid space** is recommended as easy and safe location for puncture. Cerebrospinal fluid is found to contain none of the properties of lymph and the perivascular lymphatic sheaths do not empty into the subarachnoid space. Liquids injected by lumbar puncture diffuse rapidly toward the cavities of the brain and reach the cortex. The difference in osmotic currents and the protection of the perivascular lymphatic sheaths explains the rarity of infection of the cerebrospinal fluid from blood-infections and the gravity of primary infections of the cerebrospinal fluid. Direct intramedullary medication deserves further trial. Subarachnoid injections of cocaine are safe if made with precautions. The solution should be fresh, injected slowly at a temperature of 37°C.; in amounts of not over 3 cc. Analgesia is proportionate in extent and duration to the amount of drug used. It appears in 5 to 35 minutes and lasts long enough for all operations in the lower limbs and pelvis. It may be of service in obstetrics. After-effects are partly due to increased pressure in the subarachnoid space, from too rapid diffusion, but they are never alarming nor lasting. One cc. of 1% cocaine solution is usually sufficient. A small amount of fluid may be withdrawn before injecting. The credit of introducing this method of anesthesia is given to an American, J. L. Corning. [M.B.T.]

3.—Haggard briefly discusses the surgery of biliary calculus without adding anything specially new to the subject. [M.B.T.]

4.—A man of 57 had suffered 5 years from recurrent gastric pain and vomiting but never hematemesis. After medicinal measures had been tried without avail the abdomen was opened and a chronic perforating ulcer was found in the superior anterior surface of the stomach near the pylorus. Pylorotomy was performed, but the patient died a few days later, probably as a result of his weakened condition before the operation. [M.B.T.]

5.—From a consideration of the results of **division of the cervical sympathetic** in the hands of various operators in the treatment of epilepsy, glaucoma and Graves' disease, Hartwig believes that Jonnesco's operation will occupy an established position among the surgical operations of the future. [M.B.T.]

6.—Among the common but generally unrecognized symptoms of eye-strain, Starr mentions: Pain in the back of the neck, mental confusion, backwardness in children, irritability, vertigo, varying character of the handwriting. Several illustrative cases are cited. [M.B.T.]

7.—Priestly reviews the symptomatology of various diseases of the pancreas and reports all the symptoms of acute pancreatitis appearing during attacks of mumps. [M.B.T.]

2.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, p. 997.

3.—Nicholson reports the case of a female child, aged 2 years and 8 months, who presented the readily recognized appearance of **sporadic cretinism**. The patient had one brother who had had convulsions in infancy and a sister who had had convulsions during the teething period. The paternal grandmother was subject to "falling sickness," which developed late in life. There was no consanguinity in the parents. During the first 4 months of the patient's life she had frequent attacks of diarrhea. At that time the child suffered from an attack of whooping-cough of 4 months' duration, which was followed by an attack of bronchitis. At this time the child was weaned, and shortly afterward the parent noticed that she had a "wizened" appearance. The condition became progressively worse and the abdomen became larger. This latter condition was less marked after diarrhea than after constipation. The first tooth did not appear until the eleventh month and the child showed no signs of intelligence. The points of interest in the physical examination are the impossibility of detecting a thyroid body after careful palpation, large pendulous abdomen, lordosis of the vertebral column, absence of sweating, deficiency of the salivary secretion, and subnormal temperature. The child was at first given $2\frac{1}{2}$ gr. thyroid powder in the food; but, owing to the occurrence of vomiting and diarrhea, this was reduced in 4 days to $1\frac{1}{2}$ grains. The improvement was rapid and is well illustrated by the photographs accompanying the paper. The child died, 9 months after the commencement of treatment, of malignant measles. Since the sister, who was not a cretin, died of the same disease, there was no reason to suspect that the improved cretin was specially susceptible to the infection. The author thinks that the child was perfectly normal at birth, and that the attack of whooping-cough and the complicating bronchitis were the exciting causes of the following condition. [J.M.S.]

Wiener klinische Wochenschrift.

February 22, 1900. [13. Jahrg., No. 8.]

1. Alimentary Glycosuria. EVIL RAIMANT.
2. A Rare Form of Aneurysm of the Descending Thoracic Aorta. MAXIMILIAN WEINBERGER and ARTHUR WEISS.
3. Traumatic Aneurysm of the Brachial Artery with Separation of the Median Nerve. Total Extirpation of the Aneurysm: Nerve Suture. KARL SINNREICH.

2.—An aneurysm of the descending aorta in a man of 54 produced pulsation and dulness over the manubrium sterni and to the right, and a decided pulsation over the upper half of the back on the right side. In front there was a loud, systolic bruit, and over the back also a loud sound. The x-ray confirmed the diagnosis of aneurysm. The patient had several large hemorrhages without any cough or other symptom, and at the autopsy a perforation was found into a bronchus of the right side. It was somewhat peculiar that although the aneurysm was large there had been very few subjective symptoms. [D.R.]

3.—A man of 51 received a stab wound in the right arm. The blood spurted in a stream immediately and after a severe hemorrhage it ceased of itself. About 3 hours later a physician applied a compression-bandage. The patient noticed that the three first fingers of the right hand were stiff and without sensation. Ten days later there was a recurrence of hemorrhage which led to fainting and ceased spontaneously; 2 days later it recurred. After 2 weeks the patient came to the hospital and a pulsating tumor the size of the hand was felt; the pulsation and bruit ceased on compression of the axillary artery. A diagnosis of traumatic aneurysm was made; there was entire paralysis of the median nerve. Taking into consideration the repeated and severe hemorrhage, operation was immediately undertaken. The aneurysmal sac was dissected out, the ends of the median nerve were freshened and sutured and the elbow was dressed in the flexed position. About a month later there was found no disturbance of motion at the wrist and pronation

was complete. There was decided motor paralysis of the second finger and of the thumb; however, these could still be brought into apposition. There was also disturbance of sensation in the second and third fingers. The methods of operating for aneurysm are discussed and a table of 35 operations accompanies the article. [M.B.T.]

1. Suture of the Bladder for Suprapubic Cystotomy. GEORG LOTHEISEN.
2. The Etiology of Malarial Parasites. XAVER LEWKOWICZ.
3. Therapeutic Studies with Sanatogen. EDUARD RYBICKZA.

1.—Lotheissen believes that with the perfection of technic which has developed of late years, the **suprapubic operation for stone in the bladder** is rapidly superseding all others. He reports 3 cases. The first patient, a girl of 18, had lost a hairpin in the bladder 5 or 6 years previously. For 4 years no symptoms other than difficulty in urination had developed. A stone the size of a hen's egg was found at operation, in which the hairpin was embedded. The bladder was sutured, a strip of iodoform gauze was passed down to the wound and a catheter was inserted into the bladder. In a second case, a man of 53 was operated upon, and a stone weighing 303 gm. and measuring 8 cm. in length and $4\frac{1}{2}$ cm. in thickness was removed. The nucleus of the stone was oxalic acid while the surface was phosphatic; as there was considerable cystitis the bladder was not sutured. The progress of the case was at first good, but later there was arrest in the recovery and the patient eventually died of marasmus. In a third case a man of 20 years was operated upon and a stone the size of a nut was removed; the bladder was sutured tightly with 3 rows of sutures. The prevesical space was loosely packed with iodoform gauze and uneventful recovery followed. Lotheissen advocates immediate suture of the bladder in all cases in which the urine is clear, or if only slight catarrh is present. Where there are advanced pathologic changes in the mucosa of the bladder, and the urine is alkaline and decomposing, drainage of the bladder is advised. [M.B.T.]

3.—**Sanatogen** is a grayish-white powder, composed of 95% casein and 5% glycerophosphate of sodium. It is easily digestible and has been used by the author with satisfaction in a variety of affections. It stimulates the appetite, lessens the insomnia of neurasthenics, increases the bodily weight, and in some instances the hemoglobin content of the blood. [D.R.]

Deutsche medicinische Wochenschrift.

2. Red Medullary Substance and Myeloblasts. OTTO NAEGLI.
3. Physical Therapy. GOLDSCHIEDER.
4. Herpes in Women and Its Relation to Menstruation. ERNST LEVIN.

1.—Wassermann believes that the reason that **serum is often inactive** is that both the intermediate bodies and the end-bodies are not present in sufficient amount. Usually the intermediate bodies are present in sufficient quantity, while the end bodies are not. He believes it is because the end bodies, which combine with the intermediate bodies, are not present in sufficient amount that the serum is usually infectual. In order to provide more of the end-bodies he has attempted to find the proper complement for certain serums. He has found that injecting a guinea pig with a culture of typhoid and then with typhoid serum caused intoxication, but that guinea pigs which were injected in the same way, and at the time of the injection of the serum were given 4 cc. of fresh normal serum of cows' blood, showed intoxication as a result of the action of the cows' serum, but otherwise remained well. He believes, therefore, that it will be possible to find complements of the various serums which will increase their effect by containing bodies which will unite with the intermediate bodies and thus produce immunity, but that this must be sought in different animals for different serums. It will be a difficult task. [D.L.E.]

2.—Naegele expresses his personal views upon the nature of **cells in the bone marrow**. The classification of these

into small cells free from granules, which resemble lymphocytes, into cells of similar staining character, and into cells of almost the character of myelocytes is artificial, because various forms which belong midway between these are seen. Naegeli believes that the granule-free cells are entirely different from lymphocytes; he gives them the name of myeloblasts, since the myelocytes are derived from them. They differ from leukocytes because they show intermediate forms between them and the larger elements, while the lymphocytes never do; they are not always round, while lymphocytes are, and the nucleus is oftentimes oval in the myeloblasts. They do not stain so intensely, and the chromatin is regularly net-like in its arrangement while in leukocytes it is irregularly arranged. Also, he has never seen nucleoli in myeloblasts. The protoplasm of the myeloblasts shows staining with methylene-blue, in lymphocytes it is more markedly basophile. The guaiac reaction does not appear to be given by lymphocytes, but it is given by the bone marrow and probably by the myeloblasts. He also believes that pernicious anemia is testimony that the small cells of the bone marrow are myeloblasts and not lymphocytes, because in pernicious anemia there is apparently a reversion of the bone marrow to the embryonal type, and myeloblasts are embryonal forms. [D.L.E.]

3.—Goldscheider describes a number of forms of apparatus for aiding in attempted motion of paretic parts, the apparatus being so constructed that it aids the patient in each attempt at voluntary movement. He also describes thermomassage, and the use of movements in the treatment of the pains of tabes and in neuralgia. He describes a special form of stool for carrying out movements in the limbs. The details are too numerous to be given in an abstract. [D.L.E.]

3. Acute Dilation of the Heart and Cor Mobile. AUG. HOFFMANN.
4. The Relation of Epileptic Attacks to the Elimination of Uric Acid. CARO.
5. Investigation in the Etiology of Acute Exanthemata. SIEGEL.

1.—The indication for gastroenterostomosis exists when for some reason the pylorus is unable to allow the contents of the stomach to pass into the intestines, if such disability cannot be overcome by operative procedures. Unfortunately the operation of uniting the intestines to the stomach has not been attended by results always favorable. This, due either to the thickening of the opening leading from the stomach to the gut, or to bending of the efferent gut to such an angle that the gastric contents do not readily flow into it, or, as in the case reported by Kocher, to dilation of the afferent intestinal loop pressing upon the distal portion. [G.B.W.]

2.—Schüler presents a very interesting paper in which, on the basis of a number of observations, some of which he reports, he describes new methods for determining the existence of what symptomatically constitutes hyperacidity. He, with other students of Strauss, has insisted that the symptoms of hyperacidity, in a clinical sense, are not always accompanied by increase in the acidity of the stomach-contents. Schüler considers whether the acid be found high or not, if there is marked blue or bluish-violet color upon the addition of iodine, indicating that the starch is not well digested, and if the specific gravity of the stomach-contents is low, these facts show that there is hyperacidity in the sense that an alteration in excretion causes symptoms of hyperacidity. The normal specific gravity is between 1.015 and 1.020, and a specific gravity below 1.010 is practically never seen except in cases of hyperacidity. The reason that normal conditions of the acidity are found with interference in starch-digestion and in low specific gravity is difficult to state; perhaps it may be that the stomach is excessively irritable, and reacts with undue rapidity, reaching its highest point of acidity even before the end of the hour when the examination is made, and then the course of acidity de-

creases. This is questionable, but certainly such forms of clinical hyperacidity appear frequently. Schüler observed 17 in 87 cases of hyperacidity. [D.L.E.]

3.—Hoffmann reports another case to show the importance of upward dislocation of the heart by pressure from beneath, as a cause of apparent dilation. The upward dislocation of the heart causes it to turn somewhat on its axis and increases the lateral dullness. Care must be used in investigating cases of enlarged liver, distention of the stomach, etc., in order that dilation of the heart may not be considered present when it is mere torsion. [D.L.E.]

4.—A case of epilepsy was investigated for about 2 weeks. It was noticed that the uric acid varied within very wide limits, a marked reduction being seen during the 2 days preceding a severe outbreak. [This report may be considered of little value. There is no consideration of the diet during this time, and the method of determining the amount of uric acid is antiquated. D.L.E.]

2. The Relation of Blood-Pressure in Neuropathic Children. PAUL HEIM.
3. Gastroenterostomosis and Gastrostomosis and Their Relation to Gastroenterostomosis Externa. O. WITZEL and C. HOFMANN.
4. Three Cases of Fatal Parenchymatous Gastric Hemorrhage. REICHARD.

2.—Heim reports a series of determinations of the blood-pressure in neuropathic children, and compares them with the results obtained in normal children. He found the blood-pressure practically always high in the neuropathic cases as compared with the normal, also in cases with organic disease in which the symptoms were not unlike those of the neuropathic cases; otherwise he found the blood-pressure low. He therefore thinks that increase of the blood-pressure may become a matter of value in the diagnosis between organic and functional conditions. There was no apparent constant difference in the blood-pressure in various forms of neurosis. The pressure was determined by the Gaertner tonometer. [D.L.E.]

3.—To overcome the bad results which so often follow gastroenterostomosis, Witzel and Hofman suggest a new procedure which they term gastroenterostomosis externa. It consists essentially in passing a rubber tube through a gastric fistula across the stomach and into the opening leading to the efferent portion of the jejunum. The operation consists of four divisions; first, gastrostomosis after the method of Witzel is done, except that the tube is carried for a sufficient distance to reach a subsequent opening into the intestine, which distance would be about two-thirds of the length of a Nelaton's catheter; second, a posterior gastroenteranastomosis is completed up to the placing of the anterior row of sutures; third, the portion of the tube projecting into the stomach is brought out of the opening edge of the anastomosis; fourth, the gastroenteranastomosis is completed by putting in the anterior row of sutures. [G.B.W.]

4.—Reichard reports 3 cases of parenchymatous hematemesis, with fatal results. The first occurred in a man of 56, who at necropsy was found to have a chronic interstitial hepatitis. No ulcer could be found in either stomach or duodenum. In the other two cases no cause at all could be found for the hemorrhage; the first of these two presented typical symptoms of gastric ulcer, but at both the operation and postmortem no such lesion could be found. [G.B.W.]

Münchener medicinische Wochenschrift.

April 17, 1900. [47. Jahrg., No. 16.]

1. The Diagnosis of Lung Changes Caused by Inhalation of Dust. BÄUMLER.
2. The Causes of Hypertrophy of the Heart with Diseases of the Kidney. AUGUST BIER.
3. The Pathology of the Esophagus. W. FLEINER.
4. Glycosuria Among the Vagrant Classes. G. HOPPE-SEYLER.
5. A Modified Method of Microscopic Diagnosis of Bacteria; The Demonstration of Tubercle-Bacilli in the Feces. STRASBURGER.

6. Laryngitis Diabetica. OTTO LEICHTENSTERN.
7. The Psychology of Stuttering. MAX BREITUNG.
8. Material for Surgical Sutures and Ligatures. H. BRAUN.

1.—The pulmonary changes caused by the inhalation of dust may produce a clinical picture resembling tuberculosis. The patients are usually men of middle or advanced life, and have cough, expectoration, moderate fever or none at all, evidences of condensation of one or both apices, and more or less extensive bronchial catarrh. The circulation and nutrition are, as a rule, impaired. Under proper treatment the patients recuperate very promptly; in other cases the signs of emphysema appear and the disease may take on the character of chronic heart disease with loss of compensation. Tuberculosis may in some cases be added to the clinical picture. If the patient who has **pneumonokoniosis** gives up his occupation, he may recover without anything except a tendency to bronchitis. Cases of tuberculosis subjected to long-continued inhalation of dust may be favorably influenced by the tendency of the latter to cause fibroid changes. The physical signs produced by fibroid changes the result of dust-inhalation, are, principally, shrinkage of the lung, and especially, as Bäumler points out, the **retraction of the anterior margin** of the upper portion of one or both lungs. This leaves the anterior mediastinum to a greater or less extent free from lung, and changes the percussion note. [D.R.]

2.—Bier looks upon **hypertrophy of the heart** and the vascular changes in **disease of the kidney** as a compensatory hypertrophy which is useful and necessary. The secretion of the urine is largely dependent upon the blood-pressure. In diseases of the kidney a large portion of the renal structure is destroyed, and in order that sufficient urine shall be secreted by the remaining portions, the filtration-pressure must be correspondingly increased. This can only be brought about by a general increase in blood-pressure, as the system has no provision for raising the arterial pressure in one organ independently of the others. The increased secretion of urine in contracted kidney is an evidence of compensation, and is the result of the hypertrophy of the heart and the increased blood-pressure. The cause of the compensatory hypertrophy is unknown. It is probably chemical in nature. The author likewise suggests the possibility that the retention of certain substances, and possibly also an internal secretion of the kidney, may play a part. [D.R.]

4.—Hoppe-Seyler points out the occurrence of **glycosuria in vagrants**, dependent probably upon a disturbance of metabolism from insufficient nourishment, and exposure. [D.R.]

5.—The addition of alcohol to urine or other fluids containing bacteria greatly facilitates sedimentation by lessening the specific gravity of the fluid, so that the heavier bacteria sink to the bottom. Strasburger takes one part of fluid and two parts of 96% alcohol. He has also employed this method in **examining feces for tubercle-bacilli**. He was able to demonstrate the presence of these bacilli in feces that otherwise looked quite normal, but which came from patients with pulmonary tuberculosis. [D.R.]

7.—A famous actor in Meiningen suddenly became extremely hoarse at the end of the fourth act of the "Maid of Orleans." Thinking that the condition was due to cerebral fatigue and not to any local cause, Breitung wrapped the actor in blanket, ordered him to drink half a bottle of Sec, and told him to continue the performance without previously testing his voice. The suggestion succeeded admirably. The case is cited an example of voice-fatigue of cerebral origin. [D.R.]

8.—As to the strength of the **linen thread permeated with collodion**, the medium size, .35 mm., held 2,600 grams, and when tied in a hard knot, 2,200 grams. This is a marked increase in strength over the raw thread. Boiling, sterilizing with hot steam or soaking in sublimate solution had no effect on the strength or durability of the collodion-thread. The celluloid linen thread is more difficult to prepare and because of its brittleness does not stand nearly so much traction when knots have been tied. Because of the nonabsorbing qualities of the collodion-thread it can be left in the tissues for weeks without causing irritation to the stitch-canal, and when removed it will in the majority of cases be found sterile. [G.B.W.]

April 24, 1900. [47. Jahrg., No. 17.]

1. Hystereuryasis. DECKART.

2.—Eschweiler reports a case of **nasopharyngeal diphtheria** developing some time after the patient had recovered from an ordinary attack of diphtheria. There was a discharge from the right nostril, and a membrane was found in the right nasal passage, evidently ejected from the cavity of the nasopharynx into the nose. He believes that a large number of cases of so-called primary diphtheric rhinitis do not arise in the nose, but in the nasopharynx. The discharge of membranes in the nose can readily set up rhinitis. It is possible also that the persistence of bacilli after the disappearance of the membrane from the pharynx is dependent upon a diphtheric condition in the nasopharynx. It would be interesting to determine whether local treatment of the nasopharynx would not cause an early disappearance of the bacilli from the nose and pharynx. In the present instance the late development of the nasopharyngeal diphtheria was probably connected with the existence of adenoid vegetations. [D.R.]

3.—Vulpus has seen in the last 3 years 7 cases of **ruptured tendons**. In speaking of the etiology he says that in his cases there was a fatty degeneration of the tendon as proved by the microscopical examination of small excised portions. Many doubt the possibility of a voluntary contraction of a muscle being able to tear a normal tendon. In the case of the extensor of the thigh the most common seat of rupture is close to the patella. In these cases the prognosis depends on the extent of rupture unless some operative procedure is undertaken, and this is almost always the best method of treating tears of this tendon. A recurrence of course is possible where there is fatty degeneration. [G.B.W.]

4.—In **rupture of the long head of the biceps**, the groove which normally exists between the deltoid and the biceps is markedly increased and deepened so that the humerus may be readily felt between the two muscles. Rupture generally takes place at the junction of the tendon with the muscle. Because of the anatomic relation of the long tendon to the joint, when this tendon is torn a luxation of the head of the humerus in an anterior and upward direction is a fairly frequent occurrence. The case reported was a man who had received the injury 2 years previous. When examined it was seen that the head of the humerus instead of fitting exactly in the glenoid cavity was subluxated to a slight extent in an upward direction. This caused a limited range of active motion and when forced beyond this area by the surgeon a considerable amount of pain was produced. [G.B.W.]

5.—Some look upon **colica mucosa** as a neurosis; others, as a catarrhal inflammation of the colon. The author reports 4 cases of mucous discharges. In 2 of them the mucus was always evacuated with the stools; in the other 2, generally independently. In all of the cases the mucus was at times unformed, and at times constituted distinct membranes and tubular structures. The author believes that colica mucosa is an independent affection, which can be distinguished from catarrh of the colon. The differential diagnosis can only be made by a careful study of the discharges. In colica mucosa the secretion of mucus is periodical, and the stools in the intervals are normal—that is, free from mucus. If the stools contain mucus in the intervals, then the condition is one of catarrhal colitis. [D.R.]

6.—Suchannek found in a man of 46 years, on the **inside of the cheek**, especially opposite the upper molars, peculiar yellowish spots, the size of a millet-seed, which,

on excision and microscopic examination, proved to be **sebaceous glands**. The existence of these glands had been previously described by Montgomery and Hay. [D.R.]

7.—From a study of **ichthalbin** in diseases of the intestines, Rolly concludes as follows; (1) Ichthalbin, even in doses of 8 grams (120 grains) per day, does not produce any harm and does not cause constipation; (2) it favors the retention of albumin; (3) it sharpens the appetite and increases the body weight; (4) in doses of $1\frac{1}{2}$ to 3 grams (22½ to 45 grains), it lessens the quantity of ethereal sulfates in the urine; (5) it has a favorable influence on simple chronic enteritis, and on that associated with peritonitis or tuberculosis; (6) it is useful in subacute catarrh of the stomach and intestine, in acute cases it is not so valuable. The doses are: for children under 1 year, from .3 to .5 gram ($\frac{1}{4}$ to $\frac{7}{16}$ grains), thrice daily; from 1 to 5 years, 5 to 1 gram ($\frac{7}{16}$ to 15 grains) over 5 years, 1 gram (15 grains), for children and adults as a tonic, 3 to .5 gram. [D.R.]

8.—Fleiner calls attention to the existence of **spindle-shaped dilation of the esophagus** above the diaphragm, a condition that is termed **antestomach**, and to a similar condition in the subdiaphragmatic part of the esophagus, known as "**antrum cardiacum**." He has seen six instances of antestomach. In three of the cases there appeared to be several spindle shaped dilations. In two of the cases the condition was found at autopsy, and in the four others the diagnosis was based upon clinical evidence. Diverticulum of the esophagus situated low down, may be considered homologous with antestomach and with cardiac antrum. The origin of the spindle-shaped dilations is probably congenital. The condition may remain latent, but if retention of food occurs symptoms arise. These are: a sensation of pressure behind the sternum; when the sack is filled the patients have to wait until the antestomach has emptied itself. If they do not do this, each addition to the food causes stretching of the sac and intense pain. Regurgitation is very apt to occur, and sometimes rumination develops. Severe symptoms arise when impaction occurs in the lower orifice. Such symptoms of obstruction set in especially at meals. A very interesting case is detailed in which a woman at each of five pregnancies had nausea, retching without vomiting, and a sensation as if the chest were being torn asunder. There was some difficulty in swallowing and a diagnosis of diverticulum was made. Finally, Fleiner saw the patient and diagnosed a spindle-shaped dilation of the esophagus. The stomach-tube at several points met with slight resistance. At 51 cm. behind the teeth the resistance became insurmountable. During the passage of the tube 200 cc. of a turbid, offensive fluid escaped. After the esophagus had been washed out with warm water the tube could be passed into the stomach itself. The diagnosis of dilation of the esophagus may be made from the accumulation of food, drink, and saliva above the stomach. At times there is a history of difficulty in deglutition beginning early in life, suggesting a congenital anomaly of the gullet. It may be difficult to differentiate between antestomach and cardiac antrum. In such cases the Röntgen-ray may be of value, the sac being previously filled with a bismuth mixture. The treatment consists in the use of lavage of the sac, and feeding with a tube directly into the stomach. For lavage weak astringent or disinfectant solutions should be employed (salicylic acid, 1:1000), or in cases of excoriation of the mucous membrane, bismuth mixtures. The patient should also drink small quantities of Vichy water. [D.R.]

9.—Among the papers of the late Dr. Leichtenstern, an interesting article was discovered on **diabetic laryngitis**. Leichtenstern found that in some cases of diabetes the first symptom was a dryness of the throat and pharynx, a **laryngoxerosis** and **pharyngoxerosis**. It was not associated with an increased thirst or polyuria, and in a number of cases under his observation the patients had been under treatment by specialists for "catarrhal laryngitis" and other laryngeal conditions, the true nature of the disease not being recognized. He also reports a case of abscess of the larynx in a woman who had been suffering from furunculosis. The diagnosis was "idiopathic abscess," until a fruity odor of the breath suggested an examination of the urine which revealed 8% of sugar. The features of this **furunculosis diabetica laryngis**, as Leichtenstern calls it, are: 1. The acute onset of the affection under the picture of a circumscribed

edema, which rapidly passes on to abscess-formation. 2. The repetition of the process at different parts of the larynx. 3. The rapid cure of the abscess after its evacuation. 4. The absence of fever and of marked constitutional symptoms. 5. The preservation (at least in two cases observed by him) of the perichondrium. He believed, as is indicated in the name, that the multiple abscess-formation in the larynx in diabetes was the analog of furunculosis of the skin. [D.R.]

10.—The theoretic instruction of the medical student in Germany is unsurpassed by that offered in any other country. In clinical instruction, however, both France and England have reached a higher state of perfection. Müller, who recently visited the English and French medical schools, advocates a lengthening of the curriculum for the purpose of increasing the clinical instruction, and suggests that dispensaries be used for the teaching of students. [It is certainly true that the student can gain a splendid experience by attendance at dispensaries. He learns the art of history-taking, of which he acquires but little in the ordinary course of study; he becomes practically familiar with the doses of drugs and the methods of prescribing, and learns the diagnosis especially of those minor ailments which will form such a large part of his daily practice afterwards. Provision could be made in the third and fourth years for compulsory attendance at different dispensaries, the physicians at these dispensaries being associated with the medical schools as extramural teachers. It should be one of their duties to report on the work of the students, such reports having an influence upon the final grading. It must be admitted that the adoption of this plan would necessitate a revolution in the present curriculum in our large schools, but the benefits to be obtained are so great and certain that the change in the curriculum might well be undertaken. D.R.]

2. A Case of Acquired Stenosis of the Pulmonary Artery. A. KASEM BECK.

1.—Acquired stenosis of the pulmonary artery is extremely rare and very difficult of diagnosis. The case reported occurred in a man of 50 who had evidence of severe cardiac insufficiency with a systolic thrill over the body of the heart, most marked over the second left intercostal space, with general enlargement of the cardiac dulness, and upon auscultation an intense systolic murmur which was heard over the whole body of the heart and was most marked in the second intercostal space on the left. There was also a slight diastolic murmur most marked in the middle of the sternum and the second right intercostal space. The second pulmonary sound was not accentuated. Since mitral regurgitation so frequently gives rise to exactly the same signs the systolic murmur was attributed to mitral regurgitation. Necropsy showed a collection of nodules in the pulmonary artery, the lumen was narrow, the intima uneven, and near the valves there were scars to which the pulmonary valves were adherent. The nodules in the pulmonary artery proved to be gummata. The tricuspid valve was thickened and fibrous, and there was relative insufficiency of the mitral valve. A diagnosis of stenosis of the pulmonary artery might perhaps have been made upon the signs, but as a rule if the diagnosis is made upon these signs it will prove to be erroneous, and mitral regurgitation will be found. [D.L.E.]

1.—Koenig and Pels-Leusden have written quite an extensive article on **tuberculosis of the kidney**. Koenig reviewing it from the clinical standpoint and Pels-Leusden from the pathologic. There were 18 cases operated on, 6 of which were men and 12 were women. Koenig, as the result of his work, gives the following conclusions: There are two forms of kidney tuberculosis, the solitary tuberculosis of the parenchyma and the pyelitic form. The first form often runs into the second. The diagnosis in the first form is generally very uncertain, while in the second it is comparatively easy. The diagnosis as to the condition of the other kidney cannot always be made with any degree of surety, but the cystoscope and the examination of the ureters often give very helpful data. Neither nephrotomy nor resection of the kidney can effect a cure and neither is recommended, but when a healthy condition of the other organ can be ascertained a nephrectomy will add many years to the patient's life. The best results are obtained in the cases in which the disease is still limited to the parenchyma and then an absolute cure may sometimes be effected. In the pyelitic forms a complete cure can hardly be expected because of the extent of the disease. In 16 of the cases reported by Koenig, Pels-Leusden made careful pathologic studies, from which he deduces the following conclusions: 1. In all cases of tuberculosis of the kidney, in which a diagnosis could be made with sufficient positiveness to warrant an extirpation of the organ, the disease had spread so far that the pelvis of the kidney was always involved and the ureters generally so. 2. The extent of the disease in the parenchyma of the kidney is generally so diffuse that a partial resection of the organ will not suffice. To remove all the diseased portions. 3. The occurrence of a spontaneous cure of tuberculous disease of the kidney is not without the range of possibility. 4. The method by which the tuberculous process progresses through the kidney substance resembles that of the acute pyelonephritis, a figure of radiating streaks of tuberculosis being produced, which follow the direction of the urinary excreting tubules. [G.B.W.]

2.—Enderlen has carried out an extensive series of experiments on the lower animals to determine the value of **transplanting omentum in cases of defects of the urinary bladder**. He has shown that under the proper conditions the omentum unites readily with the bladder wall, and an anastomosis of the bloodvessels of the adapted surfaces takes place rapidly. Irregular bundles of connective tissue develop in the omentum and its internal surface soon becomes covered with the rapidly proliferating bladder epithelium. The epithelium in places sends prolongations into the deeper structures, especially along the suture tracts. The omentum is at first increased in size by the growth of connective tissue-cells, but later contraction occurs with resulting shrinking of the tissues. The practical use of transplanting of the omentum must in surgical procedures be limited to very few cases. Its strongest indication is to support an intraperitoneal suture of the bladder wall when subsequent leakage is thought possible. The omenta which contain much fat are more easily fastened to the bladder than the very thin ones because the latter are very easily torn by the stitches. [G.B.W.]

3.—**Cystosarcoma** of the breast which possesses epidermoidal structures is a comparatively rare tumor. Grohe reports 2 cases from his own experience. The first occurred in a married woman 27 years of age in whom the growth had been present for 5 years without causing any special inconvenience except that due to its size. The tumor after extirpation was examined microscopically and was found to consist for the greater part of a cystosarcoma. The cysts were in part lined with cylindrical cells, but in other places without any sharp border line intervening, there was a gradual change to the squamous type. Sometimes, however, the line of separation was sharply drawn and again some of the cysts showed nothing but the squamous cells. The other case was in a married woman, 48 years of age, who had noticed the growth only 4 months before presenting herself. Here the

tumor was for the most part a cystosarcoma, but with this there was a smaller portion which consisted of a pure spindle-cell sarcoma. The cysts were for the greater part lined with stratified squamous epithelium, the superficial layers of which had become horny. A few of the cysts possessed cuboidal epithelium. In many of the cysts which were lined with the stratified epithelium the cells had proliferated to such an extent that the cavity of the cysts was filled with the horny debris. Grohe closes his paper with a review of the literature on the subject of cystosarcoma. [G.B.W.]

4.—Burkhardt says that there is at present little doubt that **malignant tumors may develop in the kidney from misplaced particles of suprarenal capsule**. He reports four typical cases, and goes on to say that the symptoms of these tumors are at first so slight that the patient does not recognize until years after the growth has started, that there is anything the matter with him. During this period the tumor is of a benign nature, a true adenoma of suprarenal tissue, and it may reach great size before malignant changes become manifest. The malignant change is manifested by a rapid increase in size and the appearance of hematuria. The presence of blood in the urine is a sign that malignancy is already existent. Characteristic for these tumors is the benign beginning followed by malignant change, the former stage being much the longer in duration. The malignancy of the tumor begins when the growth breaks through its capsule of fibrous tissue and starts rapidly to penetrate the surrounding structures and gives rise to metastasis. The only treatment which is of any use is the earliest possible excision of the diseased kidney. Statistics show that the tumor is exceedingly malignant and is a disease of late life, generally occurring between 40 and 60. The growth in its early state has the form of a true adenoma of the suprarenal gland, and is made up of varying numbers of sharply encapsulated nodules. Later the nodules become diffuse and the tumors should then be classified among the carcinomas. The metastasis takes place through the lymph-channels, and by the growth penetrating into the lumen of the bloodvessels, through the vascular system. [G.B.W.]

5.—Baracz says that Stacke's is the best method of **antrotomy**, but he suggests two modifications which tend to lessen the time of healing. The difficulty in healing these cases is because of the size of the hole left after the operation and because of the poor nutrition afforded to the newly formed epithelium by the bone which is very sparsely supplied with bloodvessels. It takes from 3½ months to a year for the wounds left by this operation to heal. The modifications suggested by Baracz consist: (1) In covering the bone, still bare after the Stacke's flap has been used, by grafting by Thiersch's method; or (2) by turning up a large flap from the neighboring skin of the neck. He reports 3 cases: Nos. 1 and 2, both ears operated in the same person. Grafts after Thiersch's method were used and the wound was healed within six months after the operation. No. 3. A flap of skin was taken from the neck below the wound and turned up so that the fresh surface lay on the bone and almost the whole of the middle ear was thus covered with epithelium. The wound in this case healed within a month, but a small portion broke open and had to be closed by a second operation. [G.B.W.]

6.—In treating **retropharyngeal abscesses**, opening through the mouth possesses the one advantage of being easily and quickly done. On the other hand, it possesses many and serious disadvantages, as follows: There is danger of immediate suffocation if the discharge is great; septic pneumonia is very apt to result from the inspiration of a quantity of pus; pulmonic tuberculosis may develop in a like manner if the abscess is a result of caries of the spine; and the constant swallowing of putrid material may cause a severe gastroenteritis. Schmidt reports 15 cases, of which only 2 were tubercular, the rest being classed as idiopathic. These latter cases were all very young children, the oldest being 3 years of age. The operation of choice for opening these abscesses is by an incision along the inner border of the sternomastoid, penetrating to the outer side of the jugular vein. Drainage should be established by inserting 2 or 3 small rubber drainage tubes and packing around these with iodoform gauze. The above operation is especially adapted to the more difficult cases. The after-treatment should be conducted on the same plans as in any other phlegmon. [G.B.W.]

7.—Muehsam says that experiments on rabbits with relation to the production of **appendicitis** do not furnish data of much importance to our study of the disease when found in man. This for two reasons: First, the anatomic structure of the appendix is so different that trauma does not play as an important part in the rabbit as in man, and, secondly, the susceptibility of the two towards microorganisms is very different. However, he has carried out a series of experiments on rabbits and sums up his results about as follows: It is possible to produce gangrenous appendicitis in rabbits of a part or whole of the appendix by cutting off its nutrition through the tying of the supplying arteries. The peripheral part more easily undergoes these gangrenous changes than the central. The process is a purely local one as shown by the fact that the inflammation does not tend to spread to the neighboring structures and it is this feature which stands out most prominently in the difference between the appendicitis of the rabbit and the appendicitis of man. [G.B.W.]

8.—The case of **incarcerated obturator hernia** reported by Bernhard was a man of 67. Five days before the operation he developed the symptoms of intestinal obstruction with pain extending down the inner side of the right thigh. Examination showed the presence of a swelling about the size of a pigeon's egg just below Poupart's ligament, reaching to the beginning of the fold between the thigh and the scrotum. At the operation a very adherent hernial sac was found which contained perforated gangrenous intestine. After enlarging the hernial opening at the obturator foramen the gut was pulled down into the wound and the gangrenous portion resected. The anastomosis was made with a Murphy's button. The patient died 5 days after the operation from collapse. [G.B.W.]

9.—Lichtenauer suggests the application of the weight-extension in the **treatment of fractures of the patella**. He says that the fragments are drawn apart by the action of the extensor muscle of the thigh and this retraction he overcomes as follows: Several broad strips of adhesive plaster are placed longitudinally along the thigh from the knee upwards and fastened by a number of transverse strips, and to the ends of the longitudinal strips the weights are attached as in ordinary extension. The fragments are not secured by any special bandages, but the dressing is left open above the knee so that they may be inspected as often as required. The dressing is left on until the fragments are united, which is often from 4 to 6 weeks, and then massage of the extensor muscles is begun. One very important advantage of this method of treating fractures of the patella is that it may be readily carried out where surgical operations requiring aseptic technic cannot be safely done. [O.B.W.]

Revue de Médecine.

May 10, 1900. [20me Année, No. 5.]

1. Desquamation in Typhoid Fever in the Adult. P. REMLINGER.
2. Clinical Study on Some Infectious Diseases. H. ROGER.
3. The Function of the Thyroid Body. G. GAUTHIER.

1.—Remlinger considers that **desquamation in typhoid fever** is a trophic cutaneous disorder and that it is similar to the loss of hair, so frequently seen following this disease. The histories of 6 cases are given in detail. [J.M.S.]

2.—In the isolation hospital of the Porte d'Aubervilliers, during 1899, Rogers has seen many interesting cases of **infectious disease**. The article, which deals with various features of these diseases, began in the April number and is concluded in the present issue. As in former years, mothers who were suffering from infectious diseases were allowed to nurse their babies; consequently, 15 women suffering from measles, 19 from scarlet fever, 9 from angina of which one was diphtheria, 5 from erysipelas, 2 from gastroenteritis, and 1 from mumps, nursed their children during the course of the disease. Except a moderate athrepsia, which was due to a terminal erysipelas, these children presented no accident. **Measles**.—Among the symptoms of the period of invasion it is interesting to notice rachialgia, which was very marked in 4 men and 14 women. Out of 6 pregnant women suffering from measles, 5 were delivered at term and 1 miscarried at the eighth month. In the latter case the blood from the umbilical cord gave a pure culture of streptococci. Thirty patients had had former attacks of measles; and 3 patients

who were convalescent from measles suffered from second attacks before they had left the hospital. A female patient, aged 24 years, was attacked with splenopneumonia. Examination of the sputum failed to reveal the presence of tubercle-bacilli and the patient finally put on flesh and was discharged perfectly cured. But a guinea-pig that had been inoculated with the expectoration from this patient, died 5 months later, and then the viscera were found to be riddled with tubercles. The author records one case of hysteria following measles. More frequently than usual this year new morbilliform eruptions were noted after the termination of measles. These exanthemata may be divided into 2 classes characterized by the presence or absence of catarrhal symptoms. **Scarlet fever**.—Twenty-three patients gave a history of a former attack of scarlet fever; 11 patients presented cardiac lesions that were sequels of rheumatism; these lesions were not influenced by the disease. The urinary apparatus may suffer from functional disorders or from organic lesions in the course of scarlet fever; 3 patients suffered from the coexistence of scarlet fever and measles and 2 from scarlet fever and typhoid fever. Death usually results from the predominance of the lesions in one organ; these are usually found in the kidneys, although the liver, the spleen and the heart may be involved. Purulent coryza is a dangerous complication. Out of 3 adult patients presenting this complication, 2 died. Bacteriologic examination of the nasal discharges from one of the fatal cases showed a pure culture of streptococci; from the other fatal case, a mixed culture of streptococcus and Staphylococcus pyogenes aureus was obtained. In late childhood this complication is more serious than in the adult; out of 17 patients presenting it, 6 died. During convalescence, a child, aged 8 years, developed choreiform movements and hemianesthesia of the left side and later presented a well-marked hysteric attack. Another child presented astasia abasia. Scarlet fever is very rare in children under 2 years of age; the author notes 11 cases in children under this age. **Varicella**.—Two cases of pemphigoid varicella are noted, one of which proved fatal. Another patient died of an acute enteritis that developed in the course of the disease. In 4 years the mortality from this disease has been 41%. **Erysipelas**.—In 21% of male patients and 28% of female patients extra cardiac murmurs have been noted. On the other hand, no organic lesions have been seen to develop during the course of erysipelas, and, indeed, patients who have had old cardiopathies have presented no new manifestations. In a woman who had just miscarried at 7 months severe erysipelas developed in the region of the genitalia and extended to the lower extremities, but was not followed by puerperal infection. Gestation pursued a normal course in 6 pregnant women who were attacked with erysipelas. There were 3 cases of the disease in newborn children; one aged one month, one aged 6 weeks, and one aged 17 months. All were cured. **Diphtheria**.—Diphtheria in adults seems to be less influenced by serumtherapy than in children. In 4 years the death-rate computed from 217 cases is as follows: before 2 years, 40.9%; from 2 to 14 years, 17.8%; adults, 13.1%; total mortality, 16.5%. **Nondiphtheric anginas**.—These affections may be divided into: (1) The erythematous anginas; and (2) the exudative anginas. The author has seen 3 cases of sore throat due to oidium albicans; these cases belong in the second group. **Mumps**.—Fifty six cases of mumps were treated, all occurring in patients between the ages of 14 and 30 years. Orchitis was the most frequent complication; in 10 cases the inflammation was unilateral and in 2 cases it was bilateral. A sharp rise in temperature almost surely indicated the occurrence of orchitis. **Gastroenteritis**.—The attacks of gastroenteritis generally assume the choleric form type. The stools have no fixed character. The disease showed a mortality of 67% in 133 cases. There were 7 cases of dysenteric form enteritis. From these cases the author isolated a microorganism that he considers pathogenic and which is similar to that described by Lemoine and by Barbier and Tollemer. In the treatment of the articular pains accompanying scarlet fever the author has had satisfactory results from the external application of salicylate of methyl. In the treatment of erysipelas the author uses very hot compresses on the inflamed skin; they are well borne. The rationale of the treatment is found in the interpretation of the dermatitis as a defensive reaction of the system which,

experiment shows, attenuates the streptococcus by favoring the flow of arterial blood to the diseased area. The hot compresses are well borne and the disease does not last, as a rule, more than 6 days. [J.M.S.]

3.—Gauthier concludes his study of the **functions of the thyroid body** by reviewing the literature on the influence of the thyroid body on the pathogenesis and therapeutics of myxedema, scleroderma, psoriasis, obesity, arrest of development, changes in the osseous system, etc. He calls attention to the power of assisting in the disassimilation of albuminoids that the thyroid body possesses. The influence of the thyroid body on the excretion of phosphates and of chlorids by the kidneys is discussed. The author is of the opinion that the greater the amount of thyroid secretion in the blood, the more the uterovarian activity is reduced and that of the mammary gland is accentuated. The author believes that all pathologic states that arise from a diminution of the nutrition may be connected with a diminished secretion of the thyroid body (hypothyroidia) and may often be benefited by thyroid treatment. [J.M.S.]

Revue de Chirurgie.

May, 1900. [20me Année, No. 5.]

1. Wounds of the Rectum. QUENU.
2. A Note on Embryology and Teratology. CH. FÉRÉ.
3. Fractures of the Neck of the Radius. A. MOUCHET.
4. Median Osteotomy of the Hyoid Bone. M. VALLES.

1.—In the treatment of **wounds of the rectum** which do not penetrate the peritoneum the first indication is to arrest the flow of blood, the next indication is the cleansing of the wound. Hemostasis can be easily effected if the wound is in the lower part of the rectum; if more highly situated it can often be located by means of the rectoscope; the flow of blood can then be arrested by injections of cold or iced-water or by the use of Allingham's tampon. For proper cleansing of the intestine preliminary dilation of the sphincter is usually necessary; the wound may then be sutured with catgut, if possible, or drainage may be used; the bowels are confined for a few days. In wounds complicated by rupture of the bladder the chief indication is to produce free drainage of the urine, and this can be accomplished by tying a catheter into the bladder; if the peritoneal coat is penetrated laparotomy is indicated. The mortality of cases in which operation is performed is 33%, in cases where intervention is not practised the mortality is 82%. [M.B.T.]

3.—Mouchet reports 10 cases of **fracture of the neck of the radius**. From a study of these cases he decides that the mechanism of production is difficult to determine; probably indirect violence is responsible most frequently. Among the symptoms are mentioned swelling of the anterior and external part of the forearm, inflammation and severe pain; abnormal mobility and crepitus cannot be considered prominent symptoms and the movement of supination is impossible. X-ray photographs give the positive diagnosis. The prognosis is favorable if the fracture is properly treated soon after the injury. Treatment by massage and passive motion is recommended. Reduction is impossible and the bones cannot be retained in place if reduction is effected. Osteotomy of the neck of the radius may be necessary in case of vicious union. [M.B.T.]

4.—Valles recounts the difficulty of operations in the region of the pharynx and base of the tongue. In 1895 he first performed **osteotomy of the hyoid bone** and used the transhyoid route in extirpating a carcinoma of the epiglottis. He is convinced of the value of this procedure, which he describes in considerable detail. A number of cases are reported which were operated on successfully after this preliminary procedure. [M.B.T.]

June, 1900. [20me Année, No. 6.]

1. Carcinoma of the Large Intestine. R. DE BOVIS.
2. Polyps of the Rectum. M. PÉRAIRE.
3. Chronic Proliferating Osteomyelitis. B. ZOZLOVSKY.
4. Compression of the Pedicle of a Movable Kidney by a Gallbladder Distended with Stones. E. REYMOND.

1.—Bovis bases his article on an analysis of 426 cases which he had collected from literature. According to the statistics of surgical services, **carcinoma of the large in-**

testine occurs once for about every 2,000 to 3,000 illnesses, but according to the reports of anatomical institutes it is much more frequent, one for every 300 or 400 deaths. In relation to carcinoma affecting other organs it occurs between 2 and 5 times for every 100. The intestine is probably not much less frequently affected than the rectum, though carcinoma of the small intestine is extremely infrequent; about 53.9% of the cases are males and a little more than half of the cases are between 40 and 60 years of age. After careful study of the statistics, Bovis finds himself unable to draw any definite conclusions as to the influence of heredity, degeneration, and intoxication as causative factors. Chronic constipation is usually believed to be a common cause, but if this is so, females should be more frequently affected; this, however, is not the case. The sigmoid flexure and cecum are most frequently affected, the flexures of the colon do not seem to be more frequently affected than other parts. Annular forms occur much more frequently than lateral forms, and they more often cause stenosis; the lateral forms, however, probably favor invagination. Invagination is more likely to be caused by comparatively small tumors, when the intestinal wall is flexible and the mesentery extensible. In the progress of the disease ascites, perforation, and adhesion to neighboring organs are likely to occur. Of the forms of degeneration the gelatinous is more often met than the colloid; almost all colloid neoplasms affect the cecum. The article is continued. [M.B.T.]

2.—A woman, 38 years old, had had a tumor about the size of an orange, with a pedicle 3 cm. long and 2 cm. thick. This tumor had first escaped from the rectum during childbirth; it was replaced by the midwife and had only escaped from the rectum 3 or 4 times subsequently at stool. Defecation was painful and difficult and there was abdominal pain and constipation. After locally anesthetizing the parts with cocaine it was removed between double ligature and a perfect cure resulted. Péraire has studied the literature of **rectal polypi** thoroughly and finds the first case recorded in 1731. The symptoms most frequently complained of are pain, which is colicky in character, and frequent rectal hemorrhages; it may usually be felt by rectal examination. The progress of a case is usually slow, though it is likely to keep on increasing in size and may reach the size of 2 fists; spontaneous atrophy occasionally results. Abstracts of the cases reported in literature are given and discussed. The thermocautery is usually unnecessary to prevent hemorrhage. The application of double ligature and the use of the bistoury and scissors is sufficient. [M.B.T.]

3.—**Chronic proliferating osteomyelitis** or fibrous proliferating osteomyelitis is a rare form of disease, which has been taken by many authors for syphilis, tuberculosis or a malignant neoplasm. Kocher describes a form of typical acute suppurative osteitis which is proliferating and vascular; its chronic character often gives the idea that it is tuberculous. The granulations and excrescences which are sometimes present give the structure a strong resemblance to sarcoma. Kohler reports 3 cases of this affection which have occurred in his practice during 8 years out of about 60 cases of the ordinary form of the affection. [M.B.T.]

4.—From a search in the literature of the subject, Raymond has been unable to find a case exactly analogous to the following: A woman of 38 was taken with severe pain in the left flank following great fatigue. There was no evidence of jaundice, but she vomited almost constantly; the abdomen was distended and examination was difficult. At the region of the gallbladder an irregular hard tumor could be felt, the form of the first; below, and at one side a second mass could be felt of more homogeneous consistency and of the form of the kidney. On incision in the lumbar region the kidney was found to be about double its normal size and much discolored; at the region of the pelvis was a hard irregular mass which felt like the gallbladder distended with fluid and calculi. **Nephropexy** was performed at this time and 7 days later **cholecystotomy** was performed; about 60 gm. of purulent fluid escaped from the gallbladder at the time of the operation. The gallbladder was freed from its adhesions, 4 calculi the size of an egg removed, and the gallbladder drained. Cultures from the gallbladder showed the *B. coli communis*. The general symptoms, in part at least, were thought to be the result of the affection of the gallbladder. The functional symptoms and pain were referred to the kidney and were largely due to pressure. [M.B.T.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Mitral Stenosis.—Sansom (*Clinical Journal*, January 31, 1900) states that digitalis increases the force of action of the muscles of both ventricles. But in mitral stenosis the left ventricle does not want it, since there is no difficulty in the left ventricle unloading itself into the aorta. In these cases digitalis acts disproportionately on the right ventricle. The more powerfully the right ventricle acts the greater the amount of blood that is driven into the venous circulation, including the liver, and therefore digitalis is not likely to do much good. Five minim to 10 minim doses of the tincture, or dram doses of the infusion, or grain-doses of the leaves 3 times a day, do good for a limited time. In some cases it does no good at all. The great difficulty is that the right ventricle is overdone. Under these circumstances a great deal can be done to relieve the distention by bleeding from a vein. When the tension is thus relieved, digitalis will perhaps do good. But another cardiac tonic may be selected, namely, convallaria or caffein, particularly convallaria. When the heart-action is slow, another heart-tonic may be employed, namely, belladonna. In mitral stenosis there is a gradual narrowing of the mitral orifice going on through the course of years. Under such circumstances massage and exercise do good by helping the venous circulation and increasing the driving power of the right heart. It is not a good thing for such a patient to be taught to "cave in." Systematic bathing is also a good thing. The warm bath should be followed by a cold sponging to tone up the heart-muscle. Exercises should be graduated. This slow-going, insidious, heart-trouble must be met by gradual means calculated to assist the system over its difficulties. By these means, judiciously carried out, the patient may be placed in fair health for years.

Veratrum in Palpitation of the Heart.—According to the *New York Medical Journal*, for June 23, 1900, the following formula is well spoken of in the *Medizinische Wochenschrift* for April 23, 1900:

R.—Sodium bromid..... 1½ drams.
Tincture of veratrum viride..... 50 drops.
Sirup of orange peel 12½ drams.
Distilled water to make..... 4½ ounces.

A tablespoonful twice a day.

The Treatment of Epilepsy in Its Incipency.—W. P. Spratling, Superintendent of Craig Colony for Epileptics (*American Medical Quarterly*, April, 1900) divides epilepsy into true and false. The latter includes cases of so-called epilepsy due to some distinguishable physical infirmity, such as a strained eye-muscle, urethral stricture, a poisonous gas in the intestinal canal, or an immediate injury to the brain. Doubtless convulsions of this character may ultimately lead to genuine epilepsy. True epilepsy is largely transmitted by heredity or through hereditary influences. The disease is one of the degenerative type. The sooner we ascertain and attempt to remove the cause that creates the epileptic channel, or the epileptic focus in the individual, the greater will be the chance of a cure. This principle applies to cases of genuine epilepsy as well as to others. If the case be one of pseudoepilepsy it can be dealt with far more easily and with hopes of far better results than if it be one of true epilepsy. After 15 years' experience with the disease Spratling does not believe that it can be demonstrated that more than 6% or 8% of cases of genuine epilepsy recover; whereas with reflex epilepsy the ratio of recovery would go very much higher. The author believes that parental sympathy has stood stoutly in the way of the recovery of many cases. It has been estimated that not more than from 1% to 2% of genuine epileptics recover under home treatment, and one of the chief causes is that the physician's best efforts are defeated by parental sympathy. The principle of dietary at the Craig Colony is that patients shall have meat but once a day, and that at the noon hour, and only a small quantity; they shall have nothing fried in grease, and nothing in the way of pies, cakes or pastries. They must eat largely of

cereals, bread-stuffs, milk, fruit, eggs and butter; but there are no hard and fast lines to observe in all cases. An important element of institution treatment is the matter of discipline. In the epileptic the continuity of action is being continually broken because of a defect in his power of inhibition. In the institution he is made to feel certain ever present and active forces that tend to keep him along the line of proper conduct. For aborting expected seizures the following mixture is recommended:

R.—Potassium bromid 30 grains.
Chloral 20 grains.
Morphin sulfate ¼ grain.

Such a combination has no curative effects, though the author has known it in certain cases to hold the seizures in abeyance for months. Of the newer remedies the writer speaks favorably of the fluid extract of horse-nettle. It appears to have an advantage over bromids in not impairing the digestive functions; on the contrary, it seems to possess distinctly tonic properties. Simulo is another drug that has given excellent results. Concerning the Flechsigs treatment (opium and bromide) he has yet failed to see a case in which it produced any permanent benefit. Great stress is laid on the systematic exercise of all the muscles of the patient's body. Much can be accomplished in cases of epileptic palsy by the application of physical means for its correction.

Menorrhagia.—The following formula is given in *Le Progres Médical* (*The Therapist*, May 15, 1900):

R.—Salipyrin..... } of each..... 2½ drams.
Potass. bromid. }
Extract of viburnum prunifolium..... 5 drams.
Distilled water..... 1 ounce.
Cognac..... } of each..... 5 drams.
Sirup of orange }

A teaspoonful to be taken in the evening the fifth day before the expected period; the same quantity morning and evening on the fourth and third days; 3 teaspoonfuls on the second day, and 4 teaspoonfuls on the day before and on the day of the appearance of the menses.

Aqueous Extract of Suprarenal Gland.—Somers (*Merck's Archives*, June, 1900) draws the following conclusions from the use of the extract of suprarenal gland, in 450 cases in hospital and private practice: (1) The aqueous extract of the suprarenal gland is the most powerful astringent and vasomotor constrictor that we possess; (2) its action is peripheral, is exerted directly on the vessel walls and basement membrane, and is limited only to the parts with which the drug comes in contact; (3) it is nontoxic, nonirritating, cannot produce a vicious habit, and may be repeatedly used on the same individual without losing its power; (4) it prevents to a marked extent the toxic effects of local anesthetics by retaining them in the tissues and preventing absorption; (5) the aqueous extract readily decomposes on account of the large amount of animal matter present, but the degree of putrefaction in no way impairs the physiological activity; (6) it first blanches and then contracts mucous tissues, and will subdue active or passive inflammation; (7) its activity is not impaired by boiling and it may be repeatedly sterilized in this manner, while carbolic acid will preserve the solutions indefinitely and in no way impair their value; (8) it will prevent primary, and greatly lessen danger of secondary, hemorrhage; (9) its action is manifested in 20 seconds, attains its maximum in 5 minutes, and lasts from 1½ to 24 hours; (10) it increases the tonicity of the parts, augments the action of other drugs, especially cocaine, and diminishes postoperative swelling; (11) it markedly restricts exuberant granulation-tissue wherever situated; (12) finally, it diminishes secretion and aids in more rapid healing. He states that the following solution is a valuable local application in hay fever, and is also remarkably efficient in controlling inflammation or bleeding, and in producing anesthesia of the mucous membrane:

R.—Adrenal..... 20 grains.
Phenic acid..... 2 grains.
Eucain B..... 5 grains.
Distilled water..... 2 drams.

Macerate 10 minutes; filter.

This solution is permanent, will not decompose nor lose its physiologic activity for several months.

TOTAL EXCISION OF THE SCAPULA ALONE, AND WITH THE ARM (INTERSCAPULOTHORACIC AMPUTATION): PARTIAL EXCISION OF THE SCAPULA FOR TUMOR.

By J. J. BUCHANAN, M.D.,

of Pittsburg, Pa.

Surgeon to Mercy Hospital.

[Conclude 1 from page 37.]

GROUP III.

GENERAL REMARKS.—Total excision of the scapula with preservation of the arm has been called by Sir William Fergusson "the *ne plus ultra* of conservative surgery." It is certainly an operation most gratifying in its temporary results in malignant disease and in its permanent outcome in other conditions. The usefulness of the affected arm is remarkably little impaired by the operation. Abduction of the arm suffers most; but a variable amount even of this motion is retained. All the functions of the forearm are present, and those who perform manual labor can usually return to it, provided it does not include overhead work.

The first operation of this kind was done by von Langenbeck, in 1855; but the evolution of the complete extirpation from the partial was so gradual that the final step was but a trifling innovation, either from an operative or functional point of view, upon partial operations which had been done before by Seutin, von Bruns, and von Langenbeck himself.

Jansen, of Lyons, had removed the entire body of the bone in 1824; Skey, of London, had removed all but the glenoid process in 1830; Seutin had removed all but part of the acromion in 1849; von Langenbeck had removed all but the coracoid process in 1850; and von Bruns all but the acromion and coracoid in 1853.

It is evident that von Langenbeck himself did not attach great importance to the totality of the extirpation; for there is no record of his having performed the operation again; whereas, two months after his total excision, we find that he made a partial excision for sarcoma, removing only the body of the bone.

Nearly all writers on excision of the scapula consider those operations total in which but a small part of the bone is left; but the gradations in the amount excised are so imperceptible that no satisfactory line can be drawn. The majority of such writers, however, exclude von Langenbeck's partial case, of 1850, and admit exactly similar cases of later dates.

While, in the present paper, it has been thought best to draw the line absolutely between total and partial excisions; the fact is recognized that, for all practical purposes, except with reference to recurrence, a large number of cases in the partial list are comparable in every respect to total excisions. For this reason it has been thought necessary to make a "combination statistic" to include "total and nearly total excisions."

In Table IV is a small group of cases in which the entire scapula has been removed at two or more operations. These cases have been almost invariably classed as total excisions; but, while they are such in their ultimate effects, from an operative point of view, they were at no period more than partial excisions.

In contrast with von Langenbeck's apparent indifference to the operation which he was the first to practise,

was the enthusiasm of Syme, who performed the second total extirpation, and, in common with many British authors, believed it to be the first of its kind.

INDICATIONS.—The entire scapula has been excised for morbid growths, necrosis, osteomyelitis, tuberculosis, and injury. The question whether the entire scapula should be removed in all cases of malignant disease affecting any part of it is a very important one and cannot be decided with positiveness from the statistics so far presented. In Table III and Table V will be found all the cases bearing on this question for which the writer has been able to collect the data. The analysis made of these cases in the concluding summary would appear to show that, if by removal of less than the entire body of the scapula the growth can be entirely extirpated, the operative mortality is least, while the probability of a permanent cure is greater than if the entire bone were removed. If, however, the removal of the diseased tissue requires excision of the entire body of the scapula, or more, then the immediate mortality becomes greater and the probability of permanent cure less than when the total extirpation of the bone is practised. This is contrary to the accepted belief that the treatment of a malignant growth of a bone always calls for the extirpation of the entire bone. This idea has been well expressed by Guermontez, of Lille, in advocating the total in preference to the partial excision of the scapula: "From a therapeutic point of view, it is not sufficient to remove the affected portion of bone (in osteosarcoma); the entire bone should be extirpated as if the marrow were affected in its entire extent, and the capsule of the neoplasm were formed by the periosteum."¹ The number of cases on which the opinion favoring partial excision in small growths is based is too small to reverse the principles which govern the treatment of malignant disease in other bones; but there is sufficient basis for following a conservative course in small growths till further statistics are available.

In the less malignant conditions, necrosis, osteomyelitis, and tuberculosis, each case must be a rule for itself, although it should be remembered that total excisions are no more dangerous than partial, where the entire body of the bone requires removal.

It has been very aptly said that it is hard to imagine a case of injury which would require excision of the entire scapula without involving loss of the arm. As a matter of fact, no such case has been recorded, with the single exception of Choppin's operation in 1856.

The reference to this operation in the place quoted is so clear that there is no doubt whatever that the operation was done; but there is such an absence of detail in the report that it is not at all improbable that some portion of the bone was left in place, the operator considering it a total excision even though the processes were left. This has been done by many surgeons.

METHOD OF OPERATION.—The form of incision required to uncover the bone in excision of the scapula depends frequently on the size and location of a growth, the involvement of integument by the disease, and the location of fistulous tracts in tuberculous and necrotic processes. When the shape of the flaps is a matter of choice, they may be made in a number of ways. Probably the incision most generally adopted is the T-shaped, practised by Syme. The U-incision is advised by Phelps on account of sloughing, which occurred in his own case, in which he employed the T-incision. A

¹ *Bull. Soc. Anat.-Clin. de Lille*, 1893, viii, 140.

similar incision was advised by Sedillot and Chassaignac (Hausmann).

The flaps, having been shaped, are dissected from the underlying bone. The trapezius and deltoid are separated from their attachment to the acromion and spine of the scapula, and the supraspinatus separated near its insertion. The inner border is freed by dividing the levator anguli scapulæ and the rhomboidæ close to their insertions. The posterior scapular artery will now require ligation. The inner border of the bone is lifted from the chest and the serratus magnus cut through

tilting of the bone renders possible the separation of its muscles from the coracoid process—the biceps, coracobrachialis and pectoralis minor as well as the coracohumeral ligament. The capsular ligament of the shoulder-joint being completely severed and the long heads of biceps and triceps divided, the bone can be completely removed.

The order in which the different borders of the bone are freed is varied by the exigencies of the case or the inclinations of the operator.

In cases of necrosis and tuberculosis, the subperiosteal method of Ollier is preferred and often results in almost complete regeneration of the bone.

The only change in method of any importance which has been suggested since the early operations, is that of Jeannel,² who proposes that, in every case in which it is suspected that the axillary vessels and nerves may be involved in a growth, the operation should be so conducted that it may, if desirable, be converted into a formal interscapulothoracic amputation, according to Berger's method. He makes the clavicular and posterior incision of Berger, divides the clavicular and acromial insertions of the deltoid and through this incision makes a digital examination of the relation of the growth to the vessels and nerves. He then decides whether a scapular excision alone is sufficient. If satisfactory information cannot be thus gained, he resects the external third of the clavicle, separates the muscular attachments of the coracoid and thus gains better access to the vessels and nerves. Berger³ advises almost the same procedure, resecting the clavicle primarily in every doubtful case.

DR. BUCHANAN'S CASE III.—*Total Excision of the Scapula for Sarcoma. Recovery. Recurrence in Upper Jaw 5 Years Later.*

John K., aged 34 years, previously healthy, began to have pain in the region of his left scapula one year before the present operation, which he attributed to carrying heavy boxes on that shoulder. About six months after the pain began, a small growth was discovered above the spine of the scapula. This was excised in November, 1893, by Dr. Oyer, who preserved the specimen. The growth recurred *in loco* soon after, and the pain became almost constant and quite severe.

When he applied for treatment, the specimen was secured from Dr. Oyer for microscopical examination and was found to be a sarcoma. The recurrent growth was not larger than a small hen's egg and had its seat at the outer extremity of the supraspinous fossa.

He was admitted to Mercy Hospital and the entire scapula, with the growth, was excised on March 15, 1894, Dr. R. W. Stewart assisting. The T-shaped incision was used to uncover the bone. The muscular attachments of the body of the bone were divided, the acromio-clavicular joint separated and the scapulo-humeral joint disarticulated. The scapula was then drawn from the chest, the coracoid process exposed and its muscular attachments separated.

The capsular ligament of the shoulder joint was stitched to the periosteum of the end of the clavicle with catgut and served to hold the humerus up for a time.

The patient left his bed on the third day and made a good recovery.

His arm was perfectly useful for every purpose not requiring much elevation from the body and he was able to do the work of a huckster without difficulty.

About 5 years later he had a growth, presumably of the same nature, in the upper jaw, which was burned with a caustic plaster by an irregular practitioner. It recurred in the same place and when he applied for treatment the case was considered unsuitable for radical measures.

¹ *Le Midi Méd.*, 1895, 1, 251.

² *Bull. et Mem. de la Soc. de Chir.*, Paris, 1897, xxiii, 571.

close to its attachment. While the bone is still held away from the body, the upper border is cleared and the omohyoid divided. At this time it will be necessary to tie the suprascapular artery. The arm is now drawn downward and the acromio-clavicular attachments separated and the coraco-clavicular ligaments divided from behind. The inner border is tilted forcibly forward from the chest-wall and the teres muscles and infraspinatus divided, care being taken to secure the subscapular artery before its division. Further

TABLE III.—TOTAL EXCISION OF THE SCAPULA (AT ONE OPERATION) WITH PRESERVATION OF THE ARM.

NO.	OPERATOR.	DATE OF OPERATION.	SEX AND AGE.	CONDITION REQUIRING OPERATION.	RESULT.	SUBSEQUENT HISTORY.	REMARKS.	PLACE OF RECORD.
1	V. Langenbeck, of Berlin.	May 22, 1885.	M., 12.	Malignant growth.	Recovery.	Recurrence in 109 days and death in 10 months.	Three inches of clavicle also removed.	* <i>Pock: Deutsche Klin.</i> , 1885, Nr. 38, 422.

32	Schulz, of Neumark.	Dec. 12, 1884.	M., 16.	Caries.	Recovery.	Disease of bone began in July, 1884. Head of humerus and part of clavicle also removed.	* <i>Deutsche Zeit. f. Chir.</i> , 1885-86, xxiii, 291.
33	Landonque, of Bordeaux.	March 5, 1885.	M., 34.	Chondrosarcoma.	Death.	Tumor, size of adult head. Alcoholized subject. Death from shock in 36 hours.	* <i>L'op. de Clin. Chir.</i> , Paris, 1885, 235.
34	Brinton, J., of Philadelphia.	Oct. 3, 1885.	F., 11.	Sarcoma.	Death.	* <i>Maryland Med. Jour.</i> , 1885, xv, 21.
35	Ceet, A., of Vienna.	March 5, 1885.	M., 17.	Osteomyelitis.	Recovery.	Disease of bone began 1 month before, 5 days after circumcision for inflamed prepuce. L-flap. Subperiosteal operation. Good function.	* <i>Arch. ed. Att. Soc. Ital. di Chir.</i> , 1886, Roma, 1887, iii, 415.
36	Pacl, A., of Pisa.	Nov. 16, 1886.	F., 17.	Necrosis.	Recovery.	Moderate use of arm.	* <i>La Spiciminate</i> , 1887, ix, 570.
37	Trendelenburg, H., of Bonn.	Nov. 16, 1886.	M., 42.	Sarcoma.	Recovery.	Recurrence and excision in 4 months. Later recurrence and death in 1½ years.	* <i>Trotman: Ueber die Ext. der Scap.</i> , 1887.

¹ This case has not been generally accepted. See remarks in body of paper on this point.

² This case, cited in question by Smith, and omitted by other authors, was recognized as authentic by Mr. Syme himself in a letter to Mr. Jones, of Jersey, in 1857.

TABLE III.—TOTAL EXCISION OF THE SCAPULA (AT ONE OPERATION) WITH PRESERVATION OF THE ARM.—CONTINUED.

No.	OPERATOR.	DATE OF OPERATION.	SEX AND AGE.	CONDITION REQUIRING OPERATION.	RESULT.	SUBSEQUENT HISTORY.	REMARKS.	PLACE OF RECORD.
38	MacGormick, A., of Sidney.	April, 1887.	M., 56.	Sarcoma.	Recovery.	Operations for recurrence in June and Dec., 1889. Patient well in 1898.	Tumor removed 3 years before. Growth in serratus magnus, raising scapula from thorax.	<i>Australas. Med. Gaz.</i> , 1898, xviii, 295.
39	Jeanuel, M., of Toulouse.	Sept. 16, 1887.	M., 50.	Sarcoma.	Death.		Violent wrench of arm 2½ years before. Head of humerus and axillary glands removed. Death from shock in 3 hours.	* <i>Le Mail Med.</i> , Toulouse, 1892, i, 349.
40	Cheever, D. W., of Boston.	Oct. 11, 1887.	M., 12.	Necrosis.	Death.			<i>Clin. Rec.</i> , Boston City Hospital. (Personal communication.)
41	Clayson, T. F., of Birmingham.	Feb., 1888.	F., 8.	Sarcoma.	Death.			* <i>Lancet</i> , 1892, ii, 471.
42	Chavasse, F., of Lyons.	March 9, 1888.	M., 16.	Carcin.	Recovery.		Head of humerus excised 1 year before.	<i>Traité des Fractures</i> , Paris, 1891, iii, 904.
43	Sandler, F., of Magdeburg.	May 2, 1888.	F., 23.	Sarcoma.	Death.		Death in 14 days of sarcoma of lung.	* <i>Arch. f. klin. Chir.</i> , 1889, xxxviii, 300.
44	Van der Hoeven, J., Jr.	March 7, 1889.	M., 4½.	Sarcoma.	Recovery.	No recurrence 15 months later.	Tumor arose in callus of fractured scapula. Humerus attached to clavicle.	* <i>Nederl. Tijdschrift v. Genee</i> , 1890, xxxvi, 621.
45	Perier.	Dec., 1889.	M., 55.	Sarcoma.	Recovery.	Died in 14 months of acute enterocolitis.	Good functional result.	* <i>Le Mercredi Méd.</i> , 1890, No. 5, 51.
46	Putt.	1890.	M., 45.	Sarcoma.	Recovery.			* <i>Riforma Med.</i> , Naples, May 1, 1891.
47	Curt, A., of Gera.	May 20, 1891.	F., 17.	Tuberculosis.	Recovery.		Head of humerus and part of clavicle also removed.	* Costa: <i>Arch. di Ortop.</i> , Anno x, No. 2, 459.
48	Hadrn, A. M., of New York.	Nov., 1891.	M., 59.	Sarcoma.	Death.		Death 10 weeks after operation, preceded by delirium and joint effusions.	* Hausmann: <i>Ueber die totale Exst. des Schulterb.</i> , Erlangen, 1892.
49	Phelps, A. M., of New York.	Nov., 1891.	M., 42.	Fibrosarcoma.	Recovery.	Recurrence and removal of arm on July 3, 1895. Patient well in February, 1900. (Personal communication.)	Nodular tumor, size of child's head. T-shaped incision, some sloughing of flaps.	* <i>Med. and Surg. Rep.</i> , Philadelphia, September 9, 1893.
50	Putt.	1891.	F., 17.	Sarcoma.	Recovery.	No recurrence 2 years later.	Very good functional result.	* <i>Riforma Med.</i> , Naples, May 1, 1891.
51	Jacobson, W. H. A., of London.	March 19, 1892.	F., 4½.	Sarcoma.	Recovery.	Recurrence in wound and in axilla and death April 2, 1894. (Personal communication.)	Subscapular muscle invaded. Good use of arm afterward.	* <i>The Operations of Surg.</i> , London, 1897, 151.
52	Golding-Bird, C. H., of London.	March 23, 1893.	F., 14.	Sarcoma.	Recovery.		Growth of about 2 months. Clavicle involved and part removed. T-incision. Very good use of arm after operation.	* <i>Lancet</i> , 1893, i, 1066.
53	Fabel, of Lille.	April 14, 1893.	F., 19.	Sarcoma.	Recovery.		No previous traumatism. Tumor noticed for 1 month. Very good use of arm followed.	* <i>Bull. Med. du Nord</i> , 1893, xxxii, 305.
54	Jablouay, of Lyons.	Oct. 1, 1893.	M., 57.	Tuberculosis.	Recovery.		Suppuration for 10 years before. Upper half of humerus removed. Head of humerus resected before. Good use of arm 5 years later.	* <i>Lyon Med.</i> , 1898, lxxxviii, 537.
55	Peters.	1893.	M., 21.	Necrosis.	Recovery.		Regeneration of scapula. Good use of arm.	* <i>Leuchaff: Deut. Milit. Zeit.</i> , 1895, xxiv, 116.
56	Buchanan, J. J., of Pittsburgh.	March 15, 1894.	M., 34.	Sarcoma.	Recovery.	Recurrence in upper jaw 5 years later. No recurrence <i>in situ</i> .	Growth excised 4 months before. Present growth in supraspinous fossa. Good use of arm.	* <i>Leuchaff: Deut. Milit. Zeit.</i> , 1895, xxiv, 116.
57	Chayne, W., of London.	Oct. 5, 1894.	M., 50.	Enchondroma.	Recovery.		Large tumor, involving entire scapula and weighing 10 pounds. Growth of 7 years.	* <i>Lancet</i> , 1894, ii, 1157.
58	Maddlung, of Strasbourg.	March 5, 1895.	F., 23.	Sarcoma.	Recovery.	Recurrence <i>in situ</i> and death in 5 months.	Upper end of humerus also removed.	* <i>Deutsche Zeit. f. Chir.</i> , 1896, xliii, 443.
59	Johnson, A. H., of New York.	Oct. 9, 1895.	M., 45.	Sarcoma.	Recovery.		Injured 4 years before.	* <i>N. Y. Med. Jour.</i> , 1896, lxi, 389.
60	Warren, J. C., of Boston.	Dec. 28, 1895.	M., 44.	Sarcoma.	Recovery.	Operated 3 times for recurrence in 1896; the third while skating about 1 year after operation. (Personal communication.)		* <i>Boston M. & S. Jour.</i> , 1896, cxxxiv, 511.
61	Macdonald, G. C., of San Francisco.	Jan. 31, 1896.	F., 25.	Sarcoma.	Recovery.	Recurrence growth excised early in 1898. In good health in March, 1900. (Personal communication.)	Growth of 18 months' standing. Good use of arm followed.	* <i>Occidental Med. Times</i> , 1896, x, 600.
62	Dulzard, F. K., of Glasgow.	Feb. 7, 1896.	M., 36.	Sarcoma.	Recovery.	No recurrence in Feb., 1900; in perfect health then. (Personal communication.)	Growth noticed 7 months before. Both surfaces of scapula and muscles involved. T-incision. Good use of arm followed.	* <i>Glasgow Med. Jour.</i> , 1897, xlvii, 140.
63	Rochet, V., of Lyons.	Aug. 26, 1896.	M., 13.	Tuberculosis.	Recovery.		Subperiosteal resection.	* <i>La Province Méd.</i> , 1896, x, 457.
64	Edington, G. H., of Glasgow.	Dec. 27, 1896.	F., 8.	Sarcoma.	Recovery.	No recurrence 6 months later.	Infraspinous fossa involved.	* <i>Glasgow Med. Jour.</i> , 1897, xlviii, 202.
65	Van Herson, J. E., of Leyden.	Jan. 22, 1897.	F., 30.	Sarcoma.	Recovery.		Weighted 6 kg. after excision. One week later the arm was removed for want of circulation and anesthesia.	Personal communication.
66	Berger, L., of Paris.	June 2, 1897.	F., 21.	Sarcoma.	Recovery.	Recurrence growth excised early in 1898. In good health in March, 1900. (Personal communication.)	Tumor recurrent and of large size.	* <i>Bull. et Mem. Soc. Chir. Par.</i> , 1897, xxiii, 571.
67	Robson, A. W. M., of Leeds.	July 20, 1897.	F., 20.	Sarcoma.	Recovery.	Rapid recurrence <i>in situ</i> . Second operation in 22 days; death 15 days later.	Kueber's incision.	Personal communication.
68	Moyulhan, G. B. A., of Leeds.	Sept. 16, 1897.	F., 23.	Sarcoma.	Recovery.			* <i>British Med Jour.</i> , 1898, i, 1193.
69	Plequet, L., of Paris.	Oct. 26, 1897.	F., 25.	Sarcoma.	Recovery.		Tumor size of child's head.	* <i>Bull. Soc. Anat. Par.</i> , 1897, lxxii, 919.
70	Schmidt, M., of Cuxhaven.	Dec. 5, 1897.	M., 57.	Sarcoma.	Recovery.	Recurrence in one year.	Subscapular tumor size of man's fist. End of clavicle also removed.	* <i>Deutsche Zeit. f. Chir.</i> , 1898-9, i, 394.
71	Frohlis, of Schüssel.	Summer, 1898.	M., 18.	Tuberculosis.	Recovery.		Head of humerus excised in April, 1898. Subperiosteal operation. Patient had a chronic nephritis a year later.	* <i>Therap. Monatsch.</i> , 1899, xiii, 315.
72	Golding-Bird, C. H., of London.	Jan. 10, 1900.	F., 10.	Sarcoma.	Recovery.	No recurrence in middle of February, 1900.	Swelling over scapula began after a blow from a stick. T-incision.	Personal communication.

SUMMARY OF TABLE III.

TOTAL EXCISION OF THE SCAPULA (AT ONE OPERATION) WITH PRESERVATION OF THE ARM.

For malignant growths.....	47
For semi-malignant and doubtful growths	5
For caries and necrosis.....	14
For tuberculosis	4
For osteomyelitis	1
For injury.....	1
Total	72

Malignant growths : 1, 2, 4, 6, 7, 8, 9, 11, 14, 15, 17, 19, 26, 28, 29, 30, 31, 33, 34, 37, 38, 39, 41, 43, 44, 45, 46, 48, 49, 50, 51, 52, 53, 56, 58, 59, 60, 61, 62, 64, 65, 66, 67, 68, 69, 70, 72.
Semi-malignant and doubtful growths : 12, 13, 21, 25, 57.
Caries and necrosis : 5, 10, 16, 18, 20, 22, 23, 24, 27, 32, 36, 40, 42, 55.
Tuberculosis : 47, 54, 63, 71.
Osteomyelitis : 35.
Injury : 3.

OPERATIVE MORTALITY.

For all cases, 11 deaths in 72 operations	15.3%
For neoplasm, 9 deaths in 52 operations.....	17.3%
For caries and necrosis, 1 death in 14 operations	7.1%
For tuberculosis, 4 operations.....	No mortality.
For osteomyelitis, 1 operation	No mortality.
For injury, 1 fatal case	100%

REMOTE RESULTS OF TOTAL EXCISION OF THE SCAPULA FOR NEOPLASM.

Malignant growths.

Death from operation	7
Cases without record beyond 3 years	17
Death from intercurrent or unknown causes.....	4
Later recurrence, but final result not reported	3
Recurrence followed by removal of arm, and no recurrence 5 years later	1
Death from recurrence.....	11
Free from recurrence 3 years or more	4
Total	47

Of these 19 cases (3+1+11+4) in which the remote result is known, 5 remained free from recurrence for 3 years or more, *i. e.*, 26% cured beyond the 3-year limit.

Semi-Malignant and Doubtful Growths.

One bone-cyst remained cured beyond 3 years.
One myxochondroma recurred and died in a few months.

COMBINED STATISTICS OF TOTAL AND NEARLY TOTAL EXCISION OF THE SCAPULA FOR NEOPLASM (THE ARM BEING PRESERVED).

In the summary below are included all cases of excision of the scapula for neoplasm in Tables III, IV and V, in which the entire bone, or all but the acromion or coracoid or both processes, was removed at one operation. These operations are, from an operative point of view, practically total excisions and have been tabulated together by nearly all writers. For the immediate result of operation this combination statistic is of value, but the remote results are more satisfactorily secured by examining the cases in each table separately.

Total excision of the scapula for neoplasm (at one operation) with preservation of the arm, 52 cases—9 deaths. Total excision of the scapula for neoplasm (at two operations) with preservation of the arm, 2 cases—1 death. Partial excision of the scapula for neoplasm leaving only a part or all of the acromion, or coracoid, or both, 22 cases—5 deaths. Total : 76 cases, with 15 deaths—mortality, 19.7%.

TABLE IV.—TOTAL EXCISION OF THE SCAPULA (AT TWO OR MORE OPERATIONS) WITH PRESERVATION OF THE ARM.

No.	OPERATOR.	DATE OF OPERATION.	SEX AND AGE.	CONDITION REQUIRING OPERATION.	RESULT.	SUBSEQUENT HISTORY.	REMARKS.	PLACE OF RECORD.
1	Heyfelder, J. F., of St. Petersburg.	Feb. 7, 1857.	M., 40.	Caries.	Death.	Death on eighth day. Partial excision Nov. 16, 1856.	* <i>Deutsche Klin.</i> , 1857, No. 20.
2	Bird, J. D., of Stockport.	Feb. 17, 1865.	F., 10.	Malignant growth.	Recovery.	No recurrence 18 months later. (Jacobsoo).	Original growth size of an orange. Body of bone removed Jan. 29, 1863. Head of humerus also removed at last operation.	* <i>Lancet</i> , 1865, ii, 636, and 1866, 247.
3	Kappeler, A., of Münster-linger.	April 13, 1877.	F., 25.	Enchondroma.	Recovery.	Recurrence and amputation of arm 2 years later. Died in 1881 of chondroma of spine.	Body of scapula removed in 2 operations 5 and 3 years before.	* <i>Deutsche Zeit. f. Chir.</i> , 1880-1, xiv, 305, also pers. com. from Dr. H. Walder.
4	Busch, W., of Bonn.	June 7, 1877.	F., 37.	Lymphosarcoma.	Recovery.	No recurrence 10 years later. (Hausmann.)	Body of bone removed 13 months before. Head of humerus also removed at last operation.	* Personal communication to v. Adelmann.
5	Heath, C., of London.	Feb., 1879.	M., 22.	Sarcoma.	Death.	Part of coracoid process previously removed. Death in 36 hours.	* <i>Brit. Med. Jour.</i> , 1879, i, 287.
6	Ball.	Sept. 2, 1879.	Sarcoma.	Recovery.	No recurrence 3½ years later.	Body of scapula removed March 7, 1879.	* <i>Brit. Med. Jour.</i> , 1883, i, 517.
7	Bellamy, E., of London.	Oct. 28, 1880.	M., 14.	Sarcoma.	Recovery.	All but acromion removed 26 days before. Infiltrated tissue left behind at this operation.	* <i>Lancet</i> , 1880, ii, 889.
8	Poncet, of Lyons.	April 23, 1887.	M., 26.	Necrosis.	Recovery.	Coracoid process and head of humerus previously removed.	* <i>Andry : Rev. de Chir.</i> , 1887, 988.
9	Pollosson, M., of Lyons.	1890.	Male, adult.	Necrosis.	Recovery.	Shot-wound in 1876. Head of humerus resected in 1884. Part of scapula removed in 1885. Prof. Ollier later wired end of humerus to clavicle with good result.	<i>La Proc. Med.</i> , xlii, 114.
10	Henneke, of Erlangen.	Nov. 19, 1891.	M., 33.	Chondrosarcoma.	Recovery.	Half of body of scapula removed 9 months before.	* <i>Hausmann : Ueber die totale Exstirp. des Schulterbl.</i> , Frankfurt a. M., 1892.

TABLE V.—PARTIAL EXCISION OF THE SCAPULA FOR TUMOR.

No.	OPERATOR.	DATE OF OPERATION.	SEX AND AGE.	NATURE OF TUMOR.	AMOUNT OF SCAPULA REMOVED.	RESULT.	SUBSEQUENT HISTORY.	REMARKS.	PLACE OF RECORD.
1	V. Langenbeck, B., of Berlin.	Feb. 6, 1850.	M., 36.	Enchondroma.	All but coracoid.	Death.	Enormous tumor. Death in 17 hours.	* <i>Deutsche Klin.</i> , Berlin, 1850, No. 7, 67.
2	Agnew, D. H., of Philadelphia.	June 6, 1853.	M., 27.	Sarcoma.	All but part of coracoid.	Death.	City Hosp. Record and personal communication from Prof. Ashurst.
3	Leary, J., of Heidelberg.	Oct. 9, 1854.	F., 14.	Sarcoma.	All but tip of coracoid.	Recovery.	Extensive recurrence in 4 months.	Lymphatic glands in axilla extirpated. Good functional result.	* <i>Arch. f. Clin. Chir.</i> , 1858, XXXIII, 146.
4	Lyon, of Glasgow.	Sept. 13, 1854.	F., 12.	Sarcoma.	All but coracoid.	Recovery.	Personal communication from Dr. A. Paterson.
5	Görster, A. G., of New York.	Jan. 11, 1859.	M., 8.	Sarcoma.	All but tip of coracoid.	Recovery.	No recurrence 4 months later.	Growth first noticed 3 months before.	* <i>Annals of Surgery</i> , 1900, XXXI, 257.
6	Seutin.	Nov. 19, 1859.	M., 22.	Encephaloid.	All but part of acromion.	Recovery.	Patient in a satisfactory state 2 weeks after operation. No later report.	* <i>Presse Med. Belg.</i> , Brux., 1859, I, 408.
7	Fergusson, W., of London.	June 24, 1865.	M., 25.	Encephaloma.	All but acromion.	Recovery.	Tumor size of 2 lbs.	* <i>Lancet</i> , 1865, II, 233.
8	Pollack, G., of London.	Jan. 25, 1865.	F., 16.	Malignant growth.	All but acromion.	Recovery.	Recurrence <i>in situ</i> and death in 12 months.	Suppurating and bleeding growth. Tumors of scapula had been removed twice before. Present growth weighed 6 lbs. Good use of arm followed.	* <i>Lancet</i> , 1865, II, 233. * <i>St. George's Hosp. Rep.</i> , IV, 223.
9	Schimper, M., of New Orleans.	March 30, 1865.	F., 56.	Enchondroma.	All but tip of acromion.	Recovery.	No recurrence 18 months later.	* <i>N. O. Med. Jour.</i> , 1870, XVIII, 90.
10	Jones, S., of London.	Oct. 2, 1868.	M., 43.	Enchondroma.	All but acromion.	Death.	* <i>Lancet</i> , 1868, II, 492, 635.
11	Wood, J., of London.	Feb. 20, 1875.	M., 25.	Encephaloid.	All but acromion.	Recovery.	Recurrence and death in 2½ months.	Tumor first noticed about 9 weeks before. Growth very large. Disc of tissue left.	* <i>Lancet</i> , 1875, I, 392.
12	Maclean, D., of Detroit.	Jan. 13, 1883.	F., 51.	Sarcoma.	All but acromion.	Death.	* <i>Physician and Surg.</i> , 1883, V, 413.
13	Perier, of Paris.	Dec. 1883.	M., 55.	Sarcoma.	All but acromion.	Recovery.	Tumor first noticed 5 months before.	* <i>Le Merc. Med.</i> , 1890, No. 5, 51. * <i>Bull. et Mem. Soc. Chir.</i> , Paris, 1897, XVIII, 575.
14	Park, R., of Buffalo.	Aug. 27, 1885.	M., 22.	Sarcoma.	All but acromion.	Recovery.	Recurrence in lung and death in 14 months.	Personal communication.
15	Littlewood, D., of Leeds.	Aug. 16, 1887.	M., 52.	Epididymoma.	All but acromion.	Recovery.	Recurrence and death.	* <i>Brit. Med. Jour.</i> , 1888, II, 1424.
16	v. Bruns.	1883.	F., 15.	Carcinoma.	All but acromion and coracoid.	Recovery.	Well 2½ years later.	* <i>Gies: Deutsche Zeit. f. Chir.</i> , 1880, XII, 564.
17	Symonds, C., of London.	April 1, 1884.	M., 34.	Sarcoma.	All but acromion and coracoid.	Recovery.	Subsequent history unknown. (Personal communication.)	Injury of shoulder 6 months before. Tumor appeared 1 month after injury. Synovial fluid of humerus removed 6 weeks later. Good use of arm.	* <i>Brit. Med. Jour.</i> , 1886, II, 819.
18	Hofeierich, of Greifswald.	June 17, 1887.	M., 22.	Fibrosarcoma.	All but part of acromion and part of coracoid.	Recovery.	Recurrence and death in 8 weeks.	Recurrence in lungs, liver and bodies of dorsal vertebrae. Death due to compression of cord. Syme's T-insulin.	* <i>Harburt: Ein Fall von totaler Exstirp. der Scap.</i> , Greifswald, 1887.
19	Southam, F. A., of Manchester.	June 14, 1889.	M., 14.	Sarcoma.	All but part of acromion and part of coracoid.	Recovery.	Recurrence and death in 13 months. (Later report.)	* <i>Brit. Med. Jour.</i> , 1889, II, 1337.
20	Clark, H. E., of Glasgow.	July 3, 1896.	M., 13.	Sarcoma.	All but acromion and coracoid.	Recovery.	Recurrence in lung and death early in 1899. (Personal com.)	* <i>Glasgow Med. Jour.</i> , 1896, XIV, 1.
21	Park, R., of Buffalo.	Sept. 1896.	F., 50.	Sarcoma.	All but acromion and coracoid.	Death.	Recurrence in lung and death 3 months.	Personal communication.
22	Shepherd, F. J., of Montreal.	June 26, 1896.	F., 34.	Sarcoma.	All but tip of acromion and coracoid.	Recovery.	Recurrence in lung and death early in 1899. (Personal com.)	Tumor size of a fist, confined to subscapular fossa.	* <i>Montreal Med. Jour.</i> , 1896-97, XXV, 301.
23	Skey, F. C., of London.	Oct. 18, 1896.	M., 10.	Fibrous tumor.	All but glenoid process.	Recovery.	Recurrence and death.	<i>Lancet</i> , January 1899, 13.
24	Cheever, W. W., of Boston.	Oct. 8, 1896.	F., 13.	Sarcoma.	All but glenoid process.	Death.	Recurrence and death in 3 months.	Tumor noticed 9 years before. No injury. Growth weighed 7 lbs.	Central Records, Boston City Hospital.
25	Gross, S. D., of Philadelphia.	Sept. 26, 1896.	M., 40.	Sarcoma.	All but head and acromion.	Recovery.	* <i>Am. Jour. Med Sci.</i> , 1893, xxx, 381.
26	Herz, of Erlangen.	May 20, 1896.	M., 20.	Malignant growth.	All but head and coracoid.	Death.	* <i>Stern: Über die Resektion des Schulterblattes</i> , Frankfurt, 1892.
27	Wernher, of Gießen.	Nov. 21, 1896.	M., 17.	Encephaloma.	All but glenoid process and acromion.	Recovery.	* <i>Preisg: Die Resektion der Schulterblätter</i> , 1893.
28	King, K., of Hull.	Oct. 20, 1896.	M., 26.	Osteoma.	All but glenoid process and acromion.	Recovery.	* <i>Lancet</i> , 1897, II, 914.

11	Kortz, W., of Berlin.	Jan. 17, 1891.	M., 41.	Enchondroma.	Spine and neck.	Recovery.	No recurrence in January, 1900. (Personal communication.)	Sarcoma of upper end of humerus caused by fracture. Scapula not involved. Part of clavicle removed.	<i>Deutsche med. Woch.</i> , 1892, No. 12.
12	Senn, N., of Chicago.	Feb. 9, 1898.	Sarcoma.	Glenoid process.	Recovery.	*Loc. cit.

SUMMARY OF TABLE V.

PARTIAL EXCISION OF THE SCAPULA FOR TUMOR.

For sarcoma.....	43
For carcinoma.....	5
For "malignant growths".....	17
For enchondroma.....	21
For osteoma.....	6
Not stated.....	2

Total, 94

OPERATIVE MORTALITY.

For all cases, 17 deaths in 94 operations.....	18 %
Before antiseptics (1881-2), 11 deaths in 56 operations.....	19.6 %
Since antiseptics (1881-2), 6 deaths in 38 operations.....	16 %
For cases in which <i>less than the entire body</i> was removed, 4 deaths in 44 operations.....	9 %
For cases in which <i>the entire body or more was removed</i> , 13 deaths in 50 operations.....	26 %

REMOTE RESULTS OF PARTIAL EXCISION FOR TUMOR.

Malignant Growths.

Death from operation.....	11
Cases without record beyond 3 years.....	29
Later recurrence, but final result not reported.....	3
Death from recurrence.....	18
Free from recurrence for 3 years or more.....	4
	65

Of these 25 cases (3 + 18 + 4), in which the remote result is known, 4 remained free from recurrence for 3 years or more, *i. e.*, 16% cured beyond the 3-year limit.

Malignant Growths.

Died from operation: 2, 12, 21, 24, 26, 27, 34, 39, 43, 44, 69.
Cases without record beyond 3 years: 4, 5, 6, 7, 13, 14, 17, 18, 29, 30, 35, 36, 37, 42, 46, 53, 54, 56, 58, 60, 70, 71, 74, 75, 78, 79, 82, 89, 93.
Later recurrence, but final result not reported: 3, 47, 48.
Died from recurrence: 8, 11, 15, 16, 19, 20, 22, 23, 25, 32, 33, 38, 51, 59, 63, 64, 68, 85.
Free from recurrence for 3 years or more: 49, 55, 62, 72.

MALIGNANT GROWTHS FOR WHICH LESS THAN THE ENTIRE BODY OF THE SCAPULA WAS REMOVED.

Death from operation.....	1
Cases without record beyond 3 years.....	14
Death from recurrence.....	6
Free from recurrence for 3 years or more.....	3
	24

Of these 9 cases (6 + 3) in which the remote result is known, 3 remained free from recurrence for 3 years or more, *i. e.*, 33.3% cured beyond the 3-year limit.

MALIGNANT GROWTHS FOR WHICH THE ENTIRE BODY OR MORE WAS REMOVED.

Death from operation.....	10
Cases without record beyond 3 years.....	15
Later recurrence but final result not reported.....	3
Death from recurrence.....	12
Free from recurrence for 3 years or more.....	1
	41

Of these 16 cases (3 + 12 + 1) in which the remote result is known, 1 remained free from recurrence for more than 3 years, *i. e.* 6.25% cured beyond the 3-year limit.

Enchondroma.

Of the 21 partial excisions for enchondroma, 6 of the patients died from operation, and in none of the surviving 15 patients has any history been recorded to or beyond 3 years and none is reported as recurring.

WHEN MAY A CASE OF MALIGNANT GROWTH BE CON-

SIDERED CURED? The length of time after operation, at which a patient may be considered permanently cured of a malignant growth cannot be settled from statistics made up as these have been. The cases in which the late results are reported are the only ones available for this purpose and these are necessarily in the great minority, for many reasons—the death of many operators, the inaccessibility of others, the disappearance of many patients, and the death of others from unknown causes, possibly unrecognized internal recurrences.

An examination of the cases in all of the six tables will show that the date of recurrence, or death from recurrence, is given in only 106 cases; of these, 70% had their recurrence within the first year; 18% recurred or died of recurrence in the second year; 5% in the third year; and the others at varying periods after the third year.

Considering the fact that an interval of several months usually elapses between the date of operation and the publication of the report and that, as a rule, the operator keeps trace of his patient during this period, it is not strange that *the early recurrences are the ones that are recorded*. It is also the case here that four-fifths of the operators quoted have reported but a single case and the opportunity has never arisen after the first report to publish the further history of the case, even if it becomes known to the operator.

Noting the fact that 93% of the known recurrences or deaths from recurrence have happened during the first 3 years after operation, we cannot go far wrong in adopting the classical rule of considering as cured those patients who have passed three years without recurrence.

SUMMARY.—Some facts worthy of special attention are to be found in the preceding tables. The interscapulo-thoracic amputation is primarily a very successful operation, especially when performed for neoplasm, the mortality in such cases since the general practice of antiseptics being only 8%. In the 34 cases in which it would appear to have been possible to make a disarticulation, at the shoulder, there was not a single death from operation.

Of the cases amputated for sarcoma and other malignant growths, whose subsequent history is definitely known, 18.6% were cured beyond the 3-year limit. While the immediate mortality of cases operated for sarcoma of the humerus not involving the tissues of the shoulder, is *nil*, the remote results in such cases are but little more favorable (20% of cure beyond 3 years) than in operations done for malignant growths involving the scapula and shoulder.

All the cases of interscapulo-thoracic amputation for enchondroma whose history is known remained free from recurrence. This emphasizes the comparative benignancy of these growths and the fallacy of conclusions drawn when they are included in groups of malignant neoplasms.

It is evident from Table II that, compared with other operations, excision of the scapula subsequent to disarticulation at the shoulder is less practised now than formerly, probably owing to the increasing popularity of the interscapulo-thoracic amputation. The immediate mortality of the consecutive operation for neoplasm since antiseptics has been 6.6%; but the fact that the mortality of interscapulo-thoracic amputation for neoplasm during the same period is only 8%, while the percentage of ultimate cures of malignant cases by the interscapulo-thoracic is 18.6% as against 6.25% after

the consecutive excision of the scapula, confirms the wisdom of the general preference now displayed for the primary major operation.

The case is made still stronger when it is considered that, of the 34 cases in which a primary disarticulation might have been done, there was no mortality whatever.

Eighteen per cent. of ultimate cures does not at the first glance seem to be a very favorable showing for an operation so radical and so mutilating as the inter-scapulo-thoracic amputation; and especially when even this may be reduced by the relapse of cases long after the period of three years has passed. This contingency is at least counterbalanced by the fact that, of the patients operated on during the last three years, all who are known to have died have been counted against the operation, whereas not one of those who will pass this period safely has been counted in its favor.

Excision of the entire scapula for neoplasm has an immediate mortality of 17.3% and a record of 26% of cures (to 3 years) in malignant cases.

Partial excision of the scapula for tumor, taking away less than the entire body, has an immediate mortality of 9% and a record of 33.3% of cures (to 3 years) in malignant cases.

Partial excision of the scapula for tumor, taking away the entire body or more, has an immediate mortality of 26% and a record of 6.25% of cures (to 3 years) in malignant cases.

Notwithstanding the excellent functional result of total excision of the scapula, it is not advisable, according to these statistics, to remove the entire bone, even in malignant cases, if a satisfactory excision of less than the entire body can be made. If, however, the entire body or more, is implicated then, both the immediate and remote prognosis are improved by a total removal of the bone, which should in all cases be performed.

In concluding this paper, the writer can do no less than express his thanks to the many eminent surgeons who have made known to him the ultimate results of their operations by personal communication, and have thus made the statistics here presented far more complete than they would otherwise have been.

ADDENDA.—Since the completion of the present paper, a very excellent monograph has been published by Drs. Pique and Dartigues, of Paris.⁴ The authors give an extended account of Dr. Pique's case (Table III, No. 69), and a most elaborate and thoroughly illustrated dissertation on the operative technic.

Dr. J. William White, of Philadelphia, in the May issue of the *University Medical Magazine*, has reported the following cases:

1. Inter-scapulothoracic amputation for recurrent sarcoma in a man of 22 years, from whom Prof. Ashurst had removed the middle third of the clavicle four years before. The operation was performed in February, 1900, and the patient made a good recovery.

2. Excision of the scapula subsequent to disarticulation at the shoulder, done six months before. The patient was a man, 34 years of age, and the last operation was performed on April 25, 1900. Result, recovery.

Dr. Hector C. Cameron, of Glasgow, has kindly informed the writer that his patient (Table I, No. 128), operated in March, 1866, died in September, 1896, of lung disease, probably sarcomatous.

Dr. R. G. LeConte, referring to his case of inter-scapu-

lo-thoracic amputation, operated on April 12, 1899, states that the growth was a giant-cell sarcoma, that recurrent growths were removed from the first rib in January and June, 1900, and that there is now (June 20), probably a secondary growth in the mediastinum, as indicated by asthmatic attacks and displacement of the larger part of the heart to the right of the sternum.

Dr. Russell S. Fowler's patient (Table I, July 23, 1898), is now (June 19, 1900), alive and well.

The author's patient (Case 1, of the present paper) is also in good health (June 22, 1900).

A CASE OF PRIMARY ADENOCARCINOMA OF THE GALLBLADDER WITH SECONDARIES IN BOTH ADRENALS, MELANOSIS OF SKIN (ADDISON'S DISEASE?), VITILIGO, AND HYPERTROPHY OF THE PANCREAS.

By ALDRED SCOTT WARTHIN, M.D., Ph.D.,

of Ann Arbor, Mich.

Assistant Professor in Pathology, University of Michigan.

(Continued from page 40.)

EPICRISIS.—*Gallbladder Carcinoma*.—According to postmortem statistics primary carcinoma of the gallbladder is found in 5% of all cases of carcinoma (Kaufmann), but the majority of authors state that its occurrence is very rare. As stated by Ames,¹ the literature of primary cancer of the gallbladder is of recent date, the most important contributions having been made within the last 10 years. By far the majority of cases have been reported since 1870. Analysis of the cases reported in the literature will be found in Courvoisier² and Musser.³ Ames's paper contains the bibliography of the subject up to 1894. Since his report cases have been constantly appearing, and in the relatively small service of this hospital three cases have come to autopsy since 1897. Two of these I have already reported.⁴ There is, therefore, much reason for believing that the condition is not uncommon, and that perhaps the majority of cases escape observation or are incorrectly diagnosed.

The pathology of gallbladder cancer is so briefly touched upon in the various textbooks that it may be of value here to gather the sum total of the pathological knowledge of this condition. The forms described are: cylindrical-celled, simplex, medullary, colloid, scirrhus, and a very doubtful form with squamous cells. Of these the columnar-cell variety (adenocarcinoma) is by far the most frequent. It often assumes the form of a villous or polypoid growth. The origin of all these forms is directly from the epithelium of the mucosa of the gallbladder. The growth may begin in any part of the mucosa, but is most frequent in the fundus or at the neck. Courvoisier holds that the former is most often the seat of the origin of the growth, as irritation from gallstones is most likely to be produced in that part. The growth extends by diffuse infiltration or expansion leading to the formation of nodular growths in the region immediately surrounding the gallbladder, frequently extending into the liver in a tree like growth.

The gross appearance of the tumor varies greatly according to its structure. The scirrhus form is firm, whitish, like scar-tissue, and of a diffuse growth, almost always very limited in extent. The larger tumors are almost always of the columnar-cell variety. They are

⁴ Scapulectomie ou Ablation primitive et totale de l'omoplate avec conservation du membre supérieur dans les tumeurs malignes de cet os. *Revue de Chirurgie*, April, 1900.

grayish, brown, or yellowish, in color, of soft consistency, possess little stroma, and on scraping yield an abundant exudate. They usually contain cyst-like spaces filled with a colloid-like substance (mucin), and show also numerous yellowish or gray areas of necrosis. The larger masses when on a surface show umbilication. The portion of the tumor projecting into the cavity of the bladder is almost always polypoid, and may show a grayish, ulcerating surface. In those cases in which the bladder is greatly dilated numerous papillary growths may be scattered over the mucosa. Microscopically, these are found to consist of strands of epithelial cells which infiltrate the bladder-wall.

The scirrhus variety usually forms a small diffuse growth resembling the changes of chronic inflammation, and may be mistaken for this, but the neighboring lymph-glands almost always show metastasis. Often the entire peritoneum is diffusely infiltrated with a scirrhus growth giving the appearance of a diffuse fibroid thickening. The colloid form may also produce a diffuse infiltration of the peritoneum and even surround the ovaries with new-growth. It is highly probable that in some of these cases the primary seat of the growth entirely escapes observation. But in the majority of all cases the primary growth is of limited extent, so that usually portions of the original bladder-wall are preserved.

Occasionally the growth may form a universal thickening of the wall to the thickness of a finger. Tumors of the size of the fist, or rarely, of the head, may thus arise, the great size being due to a cystic dilation. These larger tumors usually contain a cavity filled with gallstones, cellular debris, and remains of bile. The fluid in the cavity may be almost black, brown, yellow, greenish, or even clear. It is frequently purulent.

More frequently the diffuse infiltration of the bladder-wall leads to a great retraction, so that the gallbladder may be concealed under the liver. As the growth around the bladder increases in size and further contraction takes place, an appearance is sometimes produced as if the gallbladder had been drawn upwards into the liver-substance, in some cases the growth being surrounded on all sides by liver-tissue. This may be explained by the fact that as the growth develops and contracts the portions of liver-tissue near the fissure are drawn toward and around the bladder, so that in some cases a tongue-like process of liver is drawn around the growth. On cutting down upon the gallbladder through the overlying liver-tissue a nodular mass is found which contains the remains of the gallbladder in the shape of a small cavity filled with stones or the debris of stones.

In these cases of marked retraction the growth is usually very small. The retraction is not confined to the scirrhus form, but may be found in any variety. In other cases the bladder may become greatly dilated, appearing as a fluctuating tumor. This may be mistaken for a simple dilation when the carcinoma is very small and in the neck of the bladder. The dilated bladder may contain bile, a thin grayish fluid, or even a clear one. Gallstones are not so frequently found in these dilated bladders as in the retracted ones, but may be present in the cystic or common ducts.

The growth of the gallbladder carcinoma is usually by extension along the wall of the cystic duct toward the liver portal, then by continuity along the hepatic and common ducts. The growth extends usually by an

infiltration of the wall of the ducts, but may take place directly through the lumen. As a rule the cystic and common ducts are wholly or partly obliterated by the growth or associated inflammatory processes. The growth by extension through the wall of the common duct may extend even to the duodenal papilla. From the liver portal the growth travels upward into the liver through Glisson's capsule compressing the intrahepatic bile-ducts and portal vessels. By extension through the liver lobules the growth may reach the hepatic veins and breaking into these lead to hematogenous metastasis.

It is stated by Courvoisier and Kaufmann that scattered secondaries throughout the liver are very rare in primary gallbladder cancer. The metastases which are usually lymphogenous are very much more frequently found in the duodenal-hepatic ligament, omentum, peritoneum, the mesenteric and retroperitoneal lymph-glands. Rarely metastatic nodules are found in the duodenal papilla. A retrograde metastasis is possible through the distended intrahepatic bile-duct. By the involvement of the branches of the portal hematogenous metastasis may be set up in other parts of the liver. Metastases in distant organs as the lungs, and kidneys, etc., are very rare in all forms of gallbladder carcinoma, and are usually the result of the extension of liver-secondaries into the hepatic veins. The kidneys may be involved by extension or metastasis through the retroperitoneal lymph-spaces. Metastases are very much more frequent in the case of adenocarcinoma variety, and may be very large and numerous. They usually have a rich blood-supply and undergo degeneration very quickly in their central portions, forming frequently cystic tumors which may much surpass the primary in size and importance. The degeneration often becomes gangrenous in character and may lead to a gangrenous pyelophlebitis with thrombosis of the branches of portal, hepatic, and vena cava. Calcareous masses are frequently found in the degenerating areas of gallbladder carcinoma, and should not be mistaken for gallstones.

The intestines, stomach and pancreas may be invaded by the extension of the tumor through inflammatory adhesions which serve as bridges. The adhesions with the colon are very common and fistulous communications may be formed at the site of these adhesions through which gallstones may escape into the bowel. Some authors believe that all cases of fistulous communication with the bowel are cancerous. Ileus may also be produced by contractions at the point of adhesion which cause twisting or kinking of the bowel. The adhesions between the gallbladder and duodenum are much less common.

In my case the extension of the tumor has taken place in all of the ways hitherto described, by continuity into the liver along the biliary passages, by extension along the common duct, by adhesions with omentum and colon, by lymphogenous metastasis through omentum, mesenteric and retroperitoneal lymph-glands, left adrenal, kidneys, and appendix, by hematogenous metastasis through both lungs, and by extension through inflammatory tissue into the right adrenal. This extension is through the lymph-spaces of the new connective tissue. This last occurrence I have been unable to find in any other case of primary gallbladder carcinoma. The widespread metastasis in this case is also very unusual.

The presence of the gallstones in the inflammatory

tissue about the right adrenal points to an earlier perforation of the bladder with the escape of the stones and their encapsulation with connective tissue. This perforation may have occurred in a distended bladder-wall or through a wall weakened by carcinoma infiltration. No evidence existed of such a perforation, as the small bladder cavity was intact and contained fluid. The growth of the carcinoma may have led later to a closure of the opening, but it seems more probable that the perforation occurred earlier, possibly preceding the growth of the cancer which may have developed primarily at the seat of perforation. No evidence existed as to the possibility of the stones escaping from the cystic or common ducts or intestine. The clinical history of the case throws no light upon this point, containing nothing which would indicate the presence of gallstones or the occurrence of a perforation.

The association of primary gallbladder carcinoma with the presence of gallstones has been known since 1856, when Klob made the observation that gallstones were present in all cases of villous cancer of the gallbladder.⁶ Frerich also noted the frequency of their coincidence. Klebs and Willigk (1869) appear to be the first who definitely affirmed that cholelithiasis is the cause of gallbladder cancer.⁶ In 1875, Hilton Fagge⁷ again emphasized the importance of the relations of the two conditions; and later v. Schüppel,⁸ Krauss,⁹ and Marchand¹⁰ confirmed these views. Zenker¹¹ found gallstones in 85% of gallbladder carcinoma. Musser's analysis of 100 cases makes the proportion 92%, Courveisier found them in 74 of 84 cases, Brodowski¹² found them in every one of 40 cases, Jayle¹³ in 23 out of 30 cases, Bertrand in 14 out of 15, Siegert in 95% of cases. Ames¹⁴ and Rolleston¹⁵ both emphasize the importance of the coincidence of the two conditions. In Ames' article the bibliography of the subject is given up to the date 1894; and the reader is referred to this paper for more extended references. In four cases seen by me here gallstones were present in every case, in three of the cases in the bladder, the fourth case being the one described above.

Schröder estimates that 14% of all cases of gallstones suffer from primary gallbladder carcinoma. Naunyn believes that half of the cases of chronic icterus diagnosed as cholelithiasis are complicated with or due to cancer alone. If this is true the condition must be much more common than is usually supposed; the usual smallness of the growth and the absence of metastases contributing to the nonrecognition of the condition.

[To be concluded.]

THE ACTION OF RENNIN UPON MILK-DIGESTION.

By I. H. CORIAT,

of Boston, Mass.

Assistant in Medical Chemistry, Tufts College Medical School, Boston.

[From the Chemical Laboratory of Tufts College Medical School.]

(Concluded from page 43.)

A GLANCE at the above tables—the end-results of the experiments detailed in this paper—will solve the problem of milk-coagulation—or, in other words, it answers the question, as to why milk must be coagulated before digestion. It is true that casein can be digested by pepsin and pancreatin, even if rennin be absent. In the case of pepsin alone, at least, coagulation can take place, and does so, through the acid reaction of the HCl. But this coagulation is an entirely different one from that of rennin—it seems that the curd formed by the HCl differs considerably and, therefore, is less easily digested than the curd formed by the enzyme. This is shown by the fact, that in all the pepsin experiments, more peptone was produced when rennin was present, than when absent—regardless of any action of HCl. With pancreatin this was different—the reaction was distinctly alkaline—there was no acid either free or combined to coagulate the casein. Here, too, in every case, when rennin was present, more of the proteid was digested. However, as will be subsequently shown, HCl need not exist free for coagulation—the combined acid will coagulate, provided it be present in sufficient amounts.

Therefore, the conclusion which we are compelled to adopt is that when rennin is present, the resulting curd is more easily and more rapidly digested by the proteolytic enzymes, and consequently, in every case, more soluble and diffusible proteid, as albumose-peptone is produced. This can only be explained by the fact of the peculiar action of rennin upon the casein of milk, forming a coagulum of a definite and invariable chemical composition. This resulting compound was acted upon more easily by the digestive enzymes. When casein is present in milk in the ordinary way, either in solution or suspension, it is acted upon less energetically by the proteolytic enzymes. Under the action of rennin, however, the casein was split up into paracasein, which was more easily attacked by both pepsin and pancreatin—and into the albumose-like whey proteid, which already was soluble to a certain extent, and possessed, even at the time of splitting, a composition related closely to the albumoses.

The rennin-function, therefore, may be summed up as follows:

1. It splits up the casein into more easily digestible proteids.
2. These resulting proteids, therefore, are converted into albumose-peptone more easily and quickly than is the casein as it exists ordinarily in milk.
3. When rennin is present, there is produced, in every case, with the proteolytic enzymes, more albumose-peptone.
4. Rennin assists the action of pepsin and pancreatin.

When we come to compare the coagulating powers of animal and vegetable enzymes on milk, that is, as to their possible identity, we have reached a field upon which little work had been done. It has been proven that vegetables and plants produce proteolytic and diastatic enzymes whose action, as far as intermediate and end-products are concerned, is almost identical with

Dr. Jameson, the raider, has been unanimously elected a member of the Cape Parliament from Kimberly. He has passed 2 or 3 medical examinations, led a body of raiders into the Transvaal, been imprisoned therefor in South Africa and in England, suffered severely from typhoid fever while besieged in Kimberly, and has had many other adventures.

those formed by the animal cell. The vegetable coagulating enzymes, however, have been but little investigated. In fact, Friedburg makes the following statement to this effect (see ref. 9): "We do not feel justified in assuming that the active principle in milk coagulation is the same in an extract of the stomach of ruminants and in the juices of certain plants. An effort will be made to show that rennin—an animal coagulating enzyme—and a vegetable coagulating enzyme—act under the same conditions of amount, acidity and coagulation time." The rennin used was in tablet form, of a definite weight, furnished by Parke, Davis & Co.

In the first place 0.650 gm. of rennin was dissolved in 100 cc water, and of this solution

1 cc.....	.0065 gm. rennin.
2 cc.....	.0130 gm. "
3 cc.....	.0195 gm. "
4 cc.....	.0260 gm. "
5 cc.....	.0325 gm. "

Varying quantities of milk (10 to 20 cc.) were placed in test-tubes, and to these were added steadily increasing quantities of the rennin solution (1 to 5 cc.). These tubes were placed in a large beaker of water, set in a flat tin vessel, partially filled with water. The temperature was kept constantly at 40° C. The coagulating time was accurately noted and was as follows :

TABLE IV.

Coagulation Time.

No.	Rennin Solution.	Milk.	Minutes.	Seconds.
1.....	1 cc.	10 cc.	1	50
2.....	2 cc.	10 cc.	1	40
3.....	3 cc.	10 cc.	1	30
4.....	4 cc.	10 cc.	1	10
5.....	5 cc.	10 cc.	1	00
6.....	1 cc.	20 cc.	3	30
7.....	2 cc.	20 cc.	2	30
8.....	3 cc.	20 cc.	2	00
9.....	4 cc.	20 cc.	1	40
10.....	5 cc.	20 cc.	1	30

From the above it will be seen that the coagulation-time grows less as the amount of rennin is increased—and that the larger the amount of milk, the longer the coagulation time. In order to compare this with taka-diastase, the same experiment was repeated. A solution of the vegetable enzyme was made up of the same strength as rennin-solution—0.650 gm. to 100 cc water. Of this solution,

1 cc.....	.0065 gm. vegetable enzyme.
2 cc.....	.0130 gm. "
3 cc.....	.0195 gm. "
4 cc.....	.0260 gm. "
5 cc.....	.0325 gm. "

The same quantities of milk were taken as above, with the vegetable enzyme solution in increasing quantities with the results as tabulated.

TABLE V.

Coagulation Time.

No.	Vegetable Enzyme Solution.	Milk.	Minutes.	Seconds.
1.....	1 cc.	10 cc.	19	00
2.....	2 cc.	10 cc.	16	50
3.....	3 cc.	10 cc.	10	10
4.....	4 cc.	10 cc.	8	00
5.....	5 cc.	10 cc.	6	30
6.....	1 cc.	20 cc.	51	30
7.....	2 cc.	20 cc.	21	20
8.....	3 cc.	20 cc.	15	40
9.....	4 cc.	20 cc.	11	10
10.....	5 cc.	20 cc.	9	30

This table also shows a decrease of coagulation-time as the amount of vegetable enzyme is increased. The

time is longer than that taken by rennin for the same amounts of milk—but we must remember, that with rennin we are working with a pure, isolated enzyme whose only function is coagulation, while the coagulating action with the vegetable enzyme is but secondary. For instance, although 1 cc. of this solution contains .0065 gm.—this amount is a mixture of foreign material and a coagulating enzyme—how much of the latter we cannot say, as it is not in an isolated form. Undoubtedly, if this coagulating enzyme could be isolated, it would be equal in its action to that of rennin, or even more powerful.

The above are simply the results of test-tube experiments in the laboratory. In the living organisms, these enzymes, whether secreted by the cells of the organism itself, or introduced from without, are subject to the manifold influences of digestion,—either helpful or inhibitory. The most potent factor influencing coagulation is, of course, HCl—as this can coagulate milk alone. With a view to determining this, it seemed advisable to try alone, and with rennin and the vegetable enzyme the action of HCl upon milk-coagulation. The following were tried.

1. The action of free HCl.
2. The action of combined HCl in varying proportions.
3. The action of combined HCl plus the coagulating enzymes.

The first may be dismissed in a few words, as all free acids, whether mineral or organic, coagulate milk. As to the action of combined HCl, detailed explanations and experiments are necessary. A solution of digestive HCl was made up, of a strength of 2.5 parts per 1000. When 1 cc. of this solution was added to 10 cc. of distilled water, it gave the tests for free HCl (Günzburg's and Töpfer's) when it was added to milk, the following results were obtained.

Milk.	HCl.	Reaction for free HCl.
10 cc.	$\frac{1}{2}$ cc.	Negative.
20 cc.	1 cc.	Negative.
10 cc.	1 cc.	Negative.
20 cc.	2 cc.	Negative.

All the HCl had entered into combination with the proteids of the milk as combined HCl (an acid albuminate), and, therefore, did not react to the tests for the free acid.

The effect of HCl upon coagulation was next considered. Free HCl was not tried, but HCl in the amounts as added above (combined) was used. First, the effect of the combined acid on coagulation was tried, with the following results, to be used as controls in the other experiments.

Milk.	HCl.	Time of Action.	Results.
5 cc.	1 cc.	2 hours.	Coagulation.
10 cc.	1 cc.	No coagulation.
10 cc.	$\frac{1}{2}$ cc.	No coagulation.
5 cc.	2 cc.	Coagulation.
10 cc.	2 cc.	Coagulation.
20 cc.	1 cc.	No coagulation.
20 cc.	2 cc.	No coagulation.

It will be readily seen from the above, that combined HCl does not coagulate milk when it is equal to $\frac{1}{16}$ or less of the bulk of milk present—but when this amount is exceeded, even combined HCl coagulates milk, without any free acid being present. If this amount ($\frac{1}{16}$) of combined HCl does not coagulate milk alone, does this increase of total acidity help the coagulation when coagulative enzymes are present? To answer this question, the same experiments under exactly the same conditions of temperature, were undertaken as above—using the same increasing amounts of rennin and the

vegetable enzyme. The only difference, of course, was the addition of varying amounts of HCl (in a combined form) with the following results:

TABLE VI.
Coagulation Time.

No.	Rennin Solution.	Milk.	HCl.	Minutes	Seconds.
1.....	1 cc.	10 cc.	1 cc.	...	20
2.....	2 cc.	10 cc.	1 cc.	...	12
3.....	3 cc.	10 cc.	1 cc.	...	06
4.....	4 cc.	10 cc.	1 cc.	...	05
5.....	5 cc.	10 cc.	1 cc.	...	04
6.....	1 cc.	20 cc.	2 cc.	...	45
7.....	2 cc.	20 cc.	2 cc.	...	30

5.....	5 cc.	10 cc.	1 cc.	2	20
6.....	1 cc.	20 cc.	2 cc.	18	00
7.....	2 cc.	20 cc.	2 cc.	16	20
8.....	3 cc.	20 cc.	2 cc.	10	00
9.....	4 cc.	20 cc.	2 cc.	8	10
10.....	5 cc.	20 cc.	2 cc.	7	00
11.....	1 cc.	10 cc.	$\frac{1}{2}$ cc.	14	50
12.....	2 cc.	10 cc.	$\frac{1}{2}$ cc.	8	20
13.....	3 cc.	10 cc.	$\frac{1}{2}$ cc.	5	30
14.....	4 cc.	10 cc.	$\frac{1}{2}$ cc.	4	30
15.....	5 cc.	10 cc.	$\frac{1}{2}$ cc.	3	30

The above shows that rennin acts more energetically and rapidly in the presence of combined HCl—the amount of acid used not being sufficient to coagulate the milk alone. The same holds true of the vegetable enzyme, proving in every case, both with and without acid, the identity of the action of the animal enzyme (rennin) and the vegetable enzyme. When the amount of HCl is less than $\frac{1}{10}$, coagulation is prolonged, but even here it is less than when HCl is entirely absent.

CONCLUSIONS.

Action of Rennin in Digestion.

1. The casein of milk can be digested by both pepsin and pancreatin, without being first coagulated by rennin.

2. When, however, rennin is present, in order to precipitate the casein, the amount of digested proteid or albumose-peptone produced by the proteolytic enzymes above mentioned, is greater in every case.

3. The presence of rennin is necessary to secure a more rapid and energetic casein-digestion.

4. This increased peptone production, due to the presence of rennin, takes place in both acid (pepsin) and alkaline (pancreatic) media.

Action of Rennin on Coagulation.

1. Combined HCl, when equal in bulk to $\frac{1}{10}$ or less of the milk used, does not coagulate milk, even after prolonged action.

2. Combined HCl, when it exceeds $\frac{1}{10}$ of the bulk of milk used, coagulates with rapidity, although not as rapidly as when HCl is free.

3. Free HCl, alone, coagulates milk.

4. Rennin coagulates milk without HCl being present, but when it is present in a combined form equal to $\frac{1}{10}$ or less of the bulk of milk used, coagulation takes place in a much shorter period of time.

5. The presence of acid-albumin hastens coagulation by the enzymes.

6. Coagulation time decreases steadily, as greater amounts of absolute rennin are present.

7. Vegetable enzymes coagulate milk in a way which compares very favorably with rennin.

8. Coagulation with vegetable enzymes takes place under the same condition of temperature, acidity and amount as rennin.

9. Enzymes exist in the plant kingdom, which have an action analogous to that of rennin.

A CASE OF MYOMA OF THE BLADDER.

By OTTO G. RAMSAY, M.D.,

of Baltimore, Md.

Instructor in Gynecology, Johns Hopkins University.

(Concluded from page 44.)

To this type of tumor rather than to the myomas belong probably the so-called infiltrating myomas of the bladder which are occasionally described. F. S. Eve¹ describes such a case under the name of myosarcoma, though Terrier and Hartmann have incorporated it into their article as a case of pure myoma. G. Nicolich² reports a like case in which the whole bladder-wall was thickened and dense, and on section was of a light rosy red color. This case was also classed as a myosarcoma.

These tumors are occasionally found multiple, several tumors appearing grouped near together or placed separately in various parts of the bladder.

The individual case reported by Terrier and Hartmann was of this variety, and there were two smaller tumors besides the single larger one demonstrated in the bladder. This case, however, cannot be certainly classed as belonging to the true myomas, both because of the malignant character which it showed in the early recurrence, and also because the pathologic description did not agree in many particulars with the accepted description of a pure myomatous tumor.

The tumors vary greatly in size from a small tumor the size of a hickory nut to enormous masses weighing several thousand grams. Polaillon and LeGrand³ report one which weighed 3,200 grams.

Clinical History.—The affection is distinctly a disease of adult life, the youngest patient being a boy of 12 years of age, operated upon by Gussenbauer.⁴

The age in the remainder of the cases collected varied from 25 to 74 years. It affects both sexes in about an equal proportion. Terrier and Hartmann, in their statistics, find that 7 males and 8 females out of 15 cases was the average, and the few cases reported since then give about the same proportion.

The rate of growth varies most probably between wide limits. Our patient had suffered with some vesical symptoms for about two years, though we cannot be at all certain that the tumor had not been present for a much longer time, and that she had only suffered dur-

ing this last period because of the onset of a slight cystitis.

Faye⁵ reports a case in which the tumor was discovered 12 years before the date of operation, and during this time it had slowly but steadily increased in size. Verhoogen's case had symptoms for 5 years before coming to him. In most of the reported cases, however, any attempt to fix the duration of the growth is merely guesswork, as symptoms were usually not complained of until the onset of hematuria or cystitis. We are safe, however, in concluding from their analogy to uterine myomas, which we know grow slowly, as well as from the fact that they occur generally in persons of early middle age, that their rate of growth is slow, and covers a period of years, before symptoms appear. The symptoms vary, naturally depending on the seat of the tumor, whether submucous and projecting into the vesical cavity, or subserous and projecting into the peritoneal cavity.

In the last-named variety the symptoms are apt to be somewhat vague and misleading, and not referred at all to the bladder. Verhoogen's patient suffered chiefly from attacks of pain in the rectum, a constant sense of pressure in this region, and at times rectal tenesmus. The only bladder-symptom was occasional frequency of micturition. A case reported by Polaillon and Le-Grand⁶ complained only of a feeling of weight in the lower abdomen, and increase in size of the abdomen; and the diagnosis rested between a myoma of the uterus and an ovarian cyst.

The submucous variety on the other hand gives rise usually to a definite set of symptoms.

Terrier and Hartmann, in discussing the symptoms of the submucous form, describe them as a combination of those usually found with vesical neoplasms, with, in addition, the physical signs of a tumor with the form and consistence of a uterine myoma. The first complaint is either of frequent or painful micturition or of hematuria.

The frequent micturition may come in attacks, with intervals of freedom from symptoms, as in our case, or it may be a constant symptom after its first appearance, slowly increasing in severity. The hematuria is an almost constant symptom in myomas, occurring in 75% of the cases, and varying in degree from the cases in which only a few red cells are to be discovered in the urine to the cases in which there is active hemorrhage, with serious loss of blood. This last form must be ascribed to the later stages, however, when there is a marked cystitis with ulceration, and any marked hemorrhage in the earlier stages is a rare exception.

Pain and vesical spasm are common, due probably to the cystitis, or possibly to the mere presence of the tumor, which acts as a foreign body. In our case the vesical spasm was almost constant, and its effect was shown by the disappearance of the urethra, from the attempt of the bladder to expel the tumor through this opening. A sense of weight in the perineum or bladder is another common symptom. If the tumor is a pedunculated movable one, there may be interference with micturition from a blocking of the internal urethral orifice by the movable tumor, and the patient will describe an inability to pass urine when in certain positions.

The tumor can usually be palpated either as a dense hardening of the anterior vaginal wall in the female, or by bimanual palpation through the vagina in the female, and through the rectum in the male. By this

last method the growth is felt as occupying distinctly the bladder region; it may be movable, or is fixed in position by a broad base, and has the dense elastic feel characteristic of the uterine myoma. The dimensions, as well as the seat and size of the base, can also be outlined with a bladder-sound, and valuable indications for treatment are obtained by the use of this instrument.

Complications.—The complications likely to occur with these growths may be easily imagined. Cystitis is almost certain to appear some time during the course of the trouble, and following this ulceration or a pericystic infection. Ascending inflammation of the ureters, with pyelitis and pyelonephritis, is also a common complication. Two cases have been described in which a beginning carcinoma of the ulcerated mucous membrane covering the tumor was found. Hyaline degeneration, necrosis of the tumor, or calcification, is almost always found.

Diagnosis.—Practically the only new growth which will give rise to the vesical symptoms associated with a pedunculate tumor is a sarcoma, and the duration of the symptoms in the myomas cover a period so much longer, and the course of the disease is so much slower, that this should serve to establish the diagnosis, though it can only be verified by a microscopical examination of a piece of the tissue.

If the tumor be smaller and not easily palpable the diagnosis is a much more difficult one, and a differential diagnosis from all varieties of vesical tumors must be made. In such cases the cystoscope is of the greatest value, as with it all of the papillomatous growths may be eliminated as well as carcinomatous or other ulcers, though in these cases also a microscopical examination is the only sure means of verifying the diagnosis.

Treatment.—This is entirely surgical and consists in the removal of the growth. In the subserous variety the removal is sometimes a comparatively simple operation for the skilled abdominal surgeon, though if the tumor lie deep in the pelvis beneath the bladder, or growing into the space of Retzius, much difficulty may be experienced in its enucleation.

In the submucous form 3 avenues of attack in the female are open; namely, to enter the bladder through the anterior abdominal wall, above the symphysis pubis, from the vagina through the vesicovaginal septum, and through the urethra after dilation. In the male there are only two routes, namely, suprapubic and perineal.

In the female all 3 avenues have been used, though apparently the favorite method is the suprapubic incision. In our case the patient would hardly have been able to stand the prolonged anesthesia and manipulation necessary in the suprapubic incision, and in our case the formation of the vesicovaginal fistula previously for drainage was another indication in favor of the vaginal route. The tumor was seized with strong forceps and dragged bodily through the fistula and brought outside of the vulva, when enucleation was easily done and the hemorrhage controlled by passing catgut sutures through the bladder tissues. Tassi⁷ has also operated through a vaginal incision for the removal of a vesical myoma. In his case the tumor was small and quite near the vaginal incision, so that he did not have much difficulty in introducing 2 wire sutures, which were carried in before removal of the tumor to avoid the possibility of hemorrhage.

It would seem possible also to enucleate through a

like vaginal opening a large myoma by morcellement, as they are like the uterine myomas in the fact that there is but a small circulation in the depths of the tissues.

Gibbons and Parker⁸ speak of a case in which the myoma was removed by a combined urethral and suprapubic operation. It was in reality, however, a suprapubic operation, as the urethra was only used to pass out the two ends of an electric wire snare with which the pedunculated myoma was slowly removed; the base was burnt after removal with a cautery iron to prevent hemorrhage.

The suprapubic route is, as mentioned before, the most popular, and under the proper conditions deservedly so, as by this route the field of operation is under the eye and the work can be more carefully and successfully done.

The most troublesome complication which is apt to arise is hemorrhage, and this may be met in one of several ways. If the base be wide and the hemorrhage free, strong catgut sutures passed through the vesical tissues and tied moderately tight will control it. The Pacquelin or actual cautery will control small bleeding areas if the hemorrhage be not too free, or if there be difficulty in passing the sutures, and the patient be in a bad condition, the application of the peroxide of iron powder or astringent solutions followed by a temporary packing of the vesical cavity will control the hemorrhage.

These means are, however, only to be used when it is found impossible to unite the edges of the bladder wound, as necessarily this is the most satisfactory if it can be carried out.

Drainage is usually necessary in these cases on account of the coincident cystitis. In the female it will be found most convenient to drain through the vagina by an artificial vesicovaginal fistula, though the suprapubic drainage in the slighter infections may be sufficient. In the male the drainage through a suprapubic wound will usually suffice.

Irrigation.—In very bad infections of the bladder it will be found useful to leave the suprapubic wound widely open, and keep the patient in a continuous hot bath, obtaining in this way the most perfect possible drainage.

In the milder cases frequent vesical irrigations using mild antiseptic or astringent solutions will suffice. Closure of the suprapubic wound entirely is hardly indicated save in the rare cases in which the infection is slight.

The results after operation for the removal of vesical myomas have been unfortunately not as good as we might expect after operation for a benign growth of this character, and this bad result may be partially explained by the severe coincident infection of bladder or kidney, or to a general septic condition. This follows evidently from the late recognition of the growth, and the development of cystitis, but at the present time there seems to be no way to avoid this late recognition, as no trouble is suspected until the onset of the cystitis calls for an examination and recognition of the tumor.

DISLOCATION OF THE JAW IN EPILEPSY.

By CHARLES J. ALDRICH, M.D.,

of Cleveland, Ohio.

Lecturer on Clinical Neurology and Anatomy of the Nervous System, College of Physicians and Surgeons; Visiting Physician and Neurologist to the Cleveland General Hospital and Dispensary; Neurologist to the Cleveland City Hospital.

DISLOCATIONS, fractures and similar accidents during the epileptic paroxysm have been occasionally noticed, but literature records such few cases of dislocation of the jaw that it must be one of the very rare complications of this very common disease. From our knowledge of the actions of the facial muscles during an epileptic paroxysm we would hardly expect a luxation to occur. The two cases hereinafter reported are examples of complete dislocation of the jaw in epilepsy, and are deemed of sufficient interest for a short report. It is of some interest to note that a correct diagnosis was not made in either case by the first physician called.

CASE 1.—Miss C., single, white female, age 21, suffered a fall at the age of five years which was followed by two or three spasms and a prolonged unconscious spell. Soon after this she began to have staring spells, on recovering from which she would keep spitting as if to put something out of her mouth. About four years ago she began to experience an occasional attack of grand mal. Following one of these attacks it was noticed that she could not close the mouth. A physician was called who failed to make the diagnosis. Another physician saw the case and sent for Dr. A. E. House, of Cleveland, who diagnosed a complete dislocation of the jaw, which was reduced under an anesthetic. Since the above report was written this patient has suffered a like injury, and was again compelled to call a surgeon to reduce the luxation.

The notes of the next case were furnished me by Dr. A. J. Smith, of Spencer, Ohio, and through whose courtesy I am enabled to give the following report:

CASE 2.—E. M., male, white, age 25, carpenter, married and a confirmed epileptic. Soon after dinner the patient threw his arms wildly about him and fell to the ground in a rigid condition, but soon commenced opening and closing his mouth with extreme violence. This was so marked that a bystander compared the action to that of a maddened animal. Suddenly it was noticed that his mouth remained permanently open. Dr. Smith was called to see the case 26 hours after the attack, but the patient had been under the care of an unlicensed practitioner who believed that the jaw was held open by the spasmodic contraction of the muscles, and applied a poultice and put the patient's feet in hot mustard water, hoping relaxation would take place; but after 26 hours had elapsed friends decided to call in Dr. Smith, who gave a small amount of anesthetic and reduced the dislocated jaw.

Thorax Resection for Empyema.—Henry Rutherford (*The Glasgow Medical Journal*, April, 1900) reports the case of a child, aged 7 years, who had suffered from a discharging empyema for more than a year. There was a tuberculous history. The patient was pale and thin, two sinuses on the left side gave vent to copious discharges. A modified Schede's operation was performed, resecting about 4½ inches of each rib from the tenth to the second inclusive. The patient made a good recovery. This case is instructive, in showing that a lung collapsed for a year or more may reexpand. On recovery there was no lateral curvature of the spinal column, but there was an atrophy of the abdominal muscles, which was probably due to the interference with intercostal nerves. When the child coughs there is bulging of the left abdominal wall as far down as the umbilicus. Another case is reported in which an operation similar to the above had to be done in successive stages with 2 to 3 months intervals. The empyema in this case was due to a perforating abscess around a tuberculous rib. [M.B.T.]

JULY 21, 1900

\$3.00 PER ANNUM

Indiscriminate abuse of manufacturers of pharmaceutical preparations is sometimes the veriest rant and cant. It is easy and self-flattering, but by no means therefore either just or wise. In view of the astonishing lapses of medical men and of their participation in pharmaceutical frauds, it tends to provoke ironic laughter. If one takes the drug-trade journals of our country and compares them dispassionately with the medical journals, one is not certain that we as a profession will appear to better advantage in the way of honor and ideality than do the manufacturers. Surely one will find as frequent proofs of fraud, shamelessness, and unscience among journals edited by doctors of medicine as in the literature of the pharmacist and manufacturers. The worst of either are bad enough, and any scorn upon our part is indicative of egotism rather than of a study of actual facts and conditions. Whatever the justice of complaints against the manufacturers, their "instruction of medical men," etc., we need not be unjust and we must not be indiscriminate in our criticisms. As a profession we are under great obligations to pharmacy and to purely commercially-motivated manufacturers for many most valuable means of progress and for much therapeutic advance itself. There are many such manufacturers who have as pure and as strictly professional aims, and who realize them as perfectly in practice, as do physicians. There are today biologic and chemic laboratories owned and operated by lay capital for the sake of money-making, and yet from which many professional laboratories might learn both science and ethics.

Studies in Metabolism.—Probably few physicians are aware of the great amount of work done by the U. S. Department of Agriculture in investigating the various problems relating to foods and to metabolism. The object of these investigations is evidently largely economic, but they are also necessarily of physiologic and general medical interest. The work is done in the office of Experiment Stations under Director A. C. True. A mere list of these publications would be surprising to most readers, and would be convincing that this department of the General Government is accomplishing work of a high order. We shall take occasion from time to time to call attention to these publications, for we consider them of great importance, but at present we wish merely to speak of one of them. This is the

Digest of Metabolism Experiments, compiled by Dr. W. O. Atwater and Dr. C. F. Langworthy. This work has involved great labor, for it is a compilation of about 3,000 experiments gathered from the literature. The whole mass is arranged systematically and tabulated so that it is comparatively easy to find conclusions; in fact, there is an air almost of mathematical precision about it that is most striking. These experiments were made upon both man and animals. The human subjects are subdivided into the healthy and the invalid. The object of the experiments was to obtain a balance in the income and outgo of one or more factors of the food—the nitrogen especially. The individuals were in various conditions, not only of health and disease, but of exercise, special diets, etc. To physicians this book gives many valuable hints as to the use and abuse of food—a subject about which they are too often in ignorance. Some of the problems are reduced here to as nearly a set of formulas as we suppose it is possible to get them, and we trust that the work thus summarized will be still further pushed to definite results by the officers of this department of the Government.

The confidence in the family physician is among the most sacred of the things placed in his care, in fact, it may be designated as the most sacred. He is looked up to by the younger generation, who have known him since their infancy, and who have sought his advice for mental as well as physical troubles; he is regarded as a friend as well as a medical adviser by those of his own age; and his word is respected by the aged whose experience has taught them how to discriminate among men. The trust reposed in him will, in time, make him the possessor of secrets which might be the undoing of many, and while not of benefit to anyone in particular, might be the ruin of a life or a family which hitherto held the respect of the community. The daily press has recently told of how such confidence was violated by a physician, and of the swift retribution that followed.

The Reorganization of the New York State Medical Association.—Every effort directed toward reform invariably develops three factions: one in favor of the movement, one opposed, and one indifferent. Especially does this appear to be the case among physicians

in matters relating to their own interests, and it probably accounts for the fact that scarcely a State in the Union has enacted laws for the benefit of the medical profession as a class. Time and again legislators have said, "Agree among yourselves what you want; then come to us and you shall have it," and as many times the advice has been ignored. What is true regarding legislative matters is equally true of the average organization of medical men for scientific work, and the reason therefor is not difficult to unearth. Lack of organization along lines that offer the fairest treatment to all concerned has sounded the death-knell of otherwise well-directed and well-intentioned efforts in almost every instance in which reform has been demanded.

In the State of New York especially this lack of cohesiveness appears to have been evident, and therefore the efforts that are now being made to completely reorganize the State Medical Association and its affiliated county associations into what will practically be one harmonious, smoothly-running body, having for its object "the cultivation and advancement of the science of medicine, the promotion of public health, and the establishment of a death-benefit fund for the dependents of its members," are worthy of the closest attention and emulation, the more so, perhaps, because they promise to be crowned with flattering success.

In order to understand why these efforts are being made at this time it will be necessary to refer briefly to the conditions obtaining in the State subsequent to the adoption by the New York State Medical Society, in 1882, of a code of ethics different from that which governs the American Medical Association, with which it was affiliated. The immediate result of this action was that, by unanimous vote, the State Society was denied representation and its delegates excluded from the annual meetings of the Association. From that time many county societies, branches of the State Society, ceased to send delegates to the annual meeting of the latter, and in 1884 the members who had seceded from the State Society, on account of its attitude regarding the code, organized the New York State Medical Association. But the prestige of the venerable State Society, founded in 1806, and, to a lesser extent, that of the several county societies, combined with the more or less imperfect knowledge of the principles for which the new association stood, undoubtedly did much to retain the membership in the older bodies of many who, otherwise, would have thrown in their fortunes with the new, and as time passed the growth of the State Association and its affiliated county branches did not keep pace with the hopes of their founders.

Membership in the State Medical Society is obtained only through the election of a member of a county society as delegate to the annual meeting of the State Society, each county society being entitled to as many delegates as there are Assembly districts in the county in which it is located. Each delegate is elected for

three years, and at the expiration of that period, on certain conditions, he is admitted to membership in the State organization. It is evident that a glaring fault in this method of representation lies in the fact that a clique in any county society may almost certainly and indefinitely prevent the election of a nominee, and it is equally evident that all the members of any one of the county societies cannot obtain membership in the parent body, no matter how strong their desire may be. The New York County Medical Society, with a membership of 1800, for instance, is represented by less than 100 permanent members, and it is entitled to but 35 delegates. A body thus organized cannot fairly represent the bulk of the profession of the State, nor can it do so until such restrictions to general membership are removed. Enjoying the distinction of being the only purely State medical organization acting under a charter, the State Medical Society naturally has been recognized by the lawmakers at Albany, and probably by the public at large, as the official mouthpiece of the medical profession, whereas, in reality, its arrogation to itself of this function has been unwarranted. As near as may be gathered, the State Society now numbers about 600 members, out of an estimated total of 9,500 medical practitioners in the State.

The first step in the plan to completely reorganize the State Medical Association and its affiliated county associations was marked by the grant of a charter to the parent organization by the Legislature in April last. This plan has been laid out on the broadest and fairest lines, and the keynote of it all is "home rule." No question of rivalry or opposition enters at all into the scheme, but equal representation, unity of purpose, and the greatest good to the greatest number—in other words, *liberté, égalité, et fraternité*. All of the county associations previously affiliated with the State Association have already voted unanimously to become parts of the new organization, and new associations are being organized in counties in which the State body has not been actively represented. As an indication of the popularity of the movement it may be noted that in several counties in which no local association existed, but in which county societies had been established, by practically unanimous vote of the members, charters from the governing body have been surrendered and application made to the State Association to take them into the fold. The membership of the State Association has increased from about 500, in April last, to nearly 1,500 on July 1.

In brief the plan may be outlined as follows: The 61 counties of the State have been grouped into 5 divisions, each division being represented by a branch, or district, association, the membership of which is made up of the members of all the county associations in the district. A person will be ineligible to membership in the State Association unless he is already a member of a county or district association. *Membership in either of these carries with it membership in the*

State Association as well, and this is the keynote of the entire scheme. Each county and each district association will elect its own officers and adopt its own by-laws, the latter being in conformity with the constitution of the State Association. The presiding officer of each county association will appoint committees on legislation, public health, and on ethics and discipline, each being subservient to and working in accord with like committees of the State Association. The local committees on ethics and discipline will pass on all charges and complaints against members, their findings being subject to the approval of their local association, but the rulings of the latter will be reviewed and final disposition of cases made by the Council of the State Association if appeal is made by the member against whom decision has been rendered.

Each county association, at its annual meeting, will elect one delegate and one alternate to serve on the nominating committee of its district association, and one member for each ten of its membership or fraction over five to a Fellowship in the State Association. The Fellows, so elected, in conjunction with the members of the Council, will direct the affairs of the Association. The Council will consist of the officers of the State Association, and the presidents of the five district associations. The duty of the nominating committee of each district association will be to nominate a full list of officers for its district organization to be elected at the annual meeting, and to elect two Fellows from all of those previously elected by the county associations, as members of the nominating committee of the State Association. It is purposed to make the initiation fee \$10.00, and the annual dues the same amount, these covering membership in the three organizations—State, district, and county. Each initiation fee will be added to the permanent fund of the State Association. Of the annual dues of each member, \$2.00 will be deposited in the treasury of the local county association, 50 cents paid to the district association, 50 cents retained by the treasurer of the county association as compensation for his services, and the balance, \$7.00, forwarded to the treasurer of the State Association. The annual dues of members assures to them the receipt of a copy of the *Medical Directory of New York, New Jersey, and Connecticut*, the publication of which was begun last year, and of the *Transactions* of each annual meeting, without additional charge. A member resigning from any county or district association, ceases at the same time to be a member of the State Association. Members will be subject to expulsion for any one of three reasons: non-payment of dues, violation of the code of ethics, and commission of a crime.

The secretary of each county association will make an annual report of the proceedings of the local organization to the secretary of the district association, and the latter will forward a report embodying these several reports and the proceedings of the

annual meeting of the district association to the secretary of the State Association, to be read at the annual meeting of the latter and incorporated in the *Transactions*. The president of each district association will be a vice-president, ex-officio, of the State Association and a member of its council. The executive committee of each district association will consist of its titular officers and the presidents of the county associations located in the district. All delegates to the American Medical Association will be appointed by the president of the State Association, in accordance with suggestions made by the presidents of the various county associations ratified by nominations of the Council, and the credentials of such delegates will be countersigned by the president and secretary of the county association to which each delegate belongs.

The two features of this reorganization scheme that probably will appeal most strongly to the average medical man are those relating to protection and assistance, and the death-benefit fund. It is proposed that the Council shall receive and investigate applications for assistance in defending members against malpractice and other suits. If in the judgment of the Council a suit is unjust, the defense of the member will be undertaken by the Association's own attorney and the full moral and financial strength of the Association exerted in the protection of the accused. No single measure will serve to attract and bind together the members of the profession more strongly than this. The knowledge that a physician will have behind him the full strength of a powerful association will certainly do much to discourage the bringing of unwarranted suits by the laity.

The plan of a death-benefit fund will not be acted on immediately, but it is hoped that when the membership in the State Association has become sufficiently large to warrant it, death benefits may be paid to the estates of deceased members from the permanent and other funds of the Association, without the necessity of levying individual assessments, as is now done by the majority of associations organized for life-insurance purposes.

It will be seen that this reorganization scheme as a whole, in addition to keeping up the standard of scientific work, aims practically to assist the members of the State organization in many ways not attempted in the past. Its success will mark an important era in the progress of the medical profession in New York, and will exert a pronounced influence on the relations of the State Association to the National organization. At the present time but 600 New York physicians are enrolled in the American Medical Association, a number entirely out of proportion to the total in the State. If the plans of the workers who have this matter in hand are carried to a successful termination, there is every reason to think that this membership will soon be much more than doubled. The voice of the Empire State will then

be heard more frequently and to better purpose in the councils of the American Medical Association, and she will take the place in the front rank to which she is justly entitled.

The Noise Nuisance.—Even Chicago has begun to recognize the injury of noise. The chief of police has classified noises into the tolerable, the intolerable, and the unavoidable. We should be inclined to exclude the first and third classes and classify all noises as intolerable. Certainly all noises injurious to health are intolerable and avoidable. But our modern American cities are pandemoniac with avoidable noises. It is perhaps not far from the truth that the "nervousness" and waste energy of our people are due to the nerve-shattering noises of our life. The few nervous systems that can withstand such ceaseless shocks are blunted into stupid dulness. Every physician and sanitarian should use all justifiable means to lessen the noise- nuisance and to bring such influences to bear upon executive officers of the city and town as may abate it. In Philadelphia the most disgraceful indifference to noise was found ultimately to be due to the fact that the police have found it useless to arrest and prosecute noise-makers as well as beggars, drunkards, insulters of women, etc., because the magistrates at once discharge the offenders unfined; the police are thus powerless to curb such impudence and lawlessness. The political boss is always the aider and abettor of crime. The drunkards and rowdy boys bawl and yell unrestrained, the dogs bark, the crazy whistlers do their worst, the street venders bellow and the buyers of old rags out-bellow them, the street-car men bang their bells, and the street-organs add to the din. In Brooklyn recently the street venders in every street, failing to invent a more diabolic noise, were ringing cow-bells. The modern trolley-car is the very acme of atrocity. It has been made so heavy and the crossing rails are so clumsily arranged that houses are jarred for a square every minute or two day and night, and dynamo-roar and bell-thumping are added. We have taught the young for a hundred years that making the most frightful noise is the way to express joy. How long will it take us to teach the healthfulness of quiet? How soon shall we learn that one has no more right to throw noises than they have to throw stones into a house? Every physician knows the baleful effect of noise upon his patients, and every physiologist understands its pathogenic effect upon the nervous system. Above all things unnecessary noises at night should be mercilessly stopped. If all the physicians and medical societies of a city should use their influence upon the city governors, the greater part of such noises could be eliminated.

Studies in Racial Dietary.—The U. S. Department of Agriculture has been making a series of interesting studies of the diet of various classes and races in this

country, and has recently published, under the superintendence of Prof. W. O. Atwater, a report on the diet of Virginia negroes. The authors of the report are Dr. H. B. Frissell, of the Hampton Institute, and Miss Isabel Bevier, of Lake Erie College. The region chosen was the eastern part of Virginia, bordering the Great Dismal Swamp, where the colored population live in a very primitive way. The poorer negroes obtain their living almost entirely from the soil, the chief products being sweet potatoes, corn, and peanuts. Near the sea, however, fish and oysters are obtained, and near the great swamp frogs, turtles, and even snakes are added to the menu. The better classes may keep a cow, but usually exchange the butter for groceries. Hog and hominy, with a little milk, are after all the mainstays. Fresh meat, other than that mentioned, is seldom eaten. The culinary habits are of the simplest kind. These colored folks seldom own a kitchen stove, but do all their cooking in an open fireplace. Consequently, the cooking is not, as a rule, well done and the nutritive value of the food not fully realized. Under the influence of the Hampton Institute the negroes are being taught better customs, but still very many of them must still live in a state not far removed from barbarism. They usually live on rented land, and one half of their crops goes for rent. Their houses are the simplest cabins, and even the water they drink is usually obtained from surface drainage and is muddy and doubtless often impure. Wheat flower is seldom obtained by these rural negroes, but only the coarsest kind of corn meal containing a large quantity of bran. This corn meal is baked without leavening. In spite of all these drawbacks, the results obtained are not so bad as might be anticipated. According to the tables in these reports, the cost of food for each person per diem is from 4 to 21 cents—but this probably includes the better classes who live in the towns. The amount of proteid is from 55 to 169 grams, and the energy from 1880 to 5350 calories. The amount of proteid in the dietary of these negroes is as large as that contained in the daily diet of white families in comfortable circumstances, and falls but little below what is called the *normal* standard. The amount of fat is large, and of carbohydrates well up to the standard. Hence, judged by its quantity and quality, the food of these Virginia negroes is amply sufficient, but it loses in value from its indigestibility and the defective culinary methods by which it is prepared.

Primary Endothelioma of the Left Superior Pulmonary Vein.—For the sake of accuracy, abstract 11 on p. 14 of the JOURNAL for July 7 should be supplemented by the statement that what was recorded in the pathologic diagnosis as chronic obliterating phlebitis of the superior pulmonary vein was concluded on histologic examination to be a primary endothelioma characterized by hyperplasia of the connective-tissue stroma and by enlargement of the lymphatic spaces and of the vasa vasorum.

Correspondence.

REGISTRATION OF TUBERCULOSIS.

By MAZYCK P. RAVENEL, M.D.,

of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

In your issue of June 2, 1900, an article by Dr. Lawrence Flick on "The Registration of Tuberculosis" appears which contains some statements liable to do much injury, and since they are dogmatically put as facts, while they are really only the opinions of Dr. Flick, and unsupported by any evidence, I beg to give some arguments on the other side.

He says: "The extermination of tuberculosis among dairy cattle is highly commendable as an economic agricultural measure, but not as a measure for the prevention of tuberculosis among human beings. While tuberculosis is frequently conveyed from human beings to animals, it is not yet certain that it is often conveyed from animals to human beings." Thus, in a few words, Dr. Flick disposes off-hand of one of the great problems of the day as a "misdirected effort." In this view he is opposed by the vast majority of investigators, health-officers, and teachers in every part of the world where tuberculosis is known. Osler, after a short review of the evidence at hand, says: "There is no reason to believe that young children, or even adults, are less susceptible to the virus than calves or pigs, so that the danger of the disease from this source (milk) is real and serious." ("Practice of Medicine," p. 267.)

In the PHILADELPHIA MEDICAL JOURNAL for December 30, 1899, a most excellent and conservative article appears by Professor J. George Adami on this subject. To the question "If infectious from animal to animal, is bovine tuberculosis infectious from animal to man?" he says: "The answer to this question is generally given as an unhesitating affirmative. I wish, however, to point out to you to-day that, *while we must accept the affirmative as the correct answer, and while it is the duty of the individual and of the State to act in full accordance with the belief that it is so*, the amount of reliable evidence of direct transmission of tuberculosis from cattle to man is singularly slight." (Italics mine.) Admittin^g fully the difficulty of absolute proof, there are numerous cases on record, such as those reported by Demme and Ollivier, which are quoted by Adami, as well as others, which rest on evidence which would be readily accepted in the case of typhoid fever, scarlet fever, diphtheria, etc., and which is at least as strong as that on which Dr. Flick bases his belief in the infectiousness of certain houses.

Dr. Flick's statement that "tuberculosis is frequently conveyed from human beings to animals" is wide of the facts. Bang, of Copenhagen, whose experience is, perhaps, greater than that of any man living, gives it as his opinion that transmission of the disease from man to the domestic animals does not often take place, and gives only three instances, two in cows and one in pigs, which he has been able to collect. Dr. Leonard Pearson, State Veterinarian, has never observed an instance of it. Dr. Pearson and myself have for a number of years made as thorough a review as possible of the literature of tuberculosis, and have been able to collect only three instances, besides those reported by Bang, of contagion from man to dairy cattle. The evidence in all of these is much the same as Dr. Flick rejects when the contagion is the other way.

Whatever may be said as to the nature of the evidence on

which we base our belief of the danger to man from tuberculosis of cattle, it is surely strong enough with all its defects to make it imperative on the individual as well as the State to guard against it by every means in our power.

"THE MALADY OF MANILA." (GONORRHEAL RHEUMATISM.)

By THEO. REPUBLICA, M.D.,

of Westfield, N. J.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

"The malady of Manila is gonorrheal rheumatism." The careful reader will please notice that this expression is not original with me. For my part, I do not care to recognize the term. It is one of those instances in which the name "rheumatism" is misapplied. But there is no question about the fact of the malady. The patients have rheumatism, and they have gonorrhea. It is articular rheumatism, and extremely severe. The patients suffering from the specific disorder are attacked with the rheumatism, and such is the morbid offence that the gonorrhea is forgotten. All agree that more severe cases of the disease were never seen than those in the Philippines. It occurs in 1 in 22 cases of illness. The local affection is particularly painful. In many cases ankylosis occurs. In most there is suppuration. The knees seem to be the principal seat of the disease, although in the majority of cases there is marked sciatica. The surgeons agree that the manifestations are those of pyarthrosis, and it would seem to me as though that would be the preferable term. It appears to be ichoremic, and they justly attribute it to the result of absorption into the blood of the morbid matter effused into or formed upon the membrane of the urethra. The pyemic condition, however, is attributable to inflammation of the prostatic veins. This special pathologic condition is of marked virulence. The sensitiveness of the part is remarkably acute. The patients complain that the touch of their clothing cannot be borne, and the degree of inflammation is almost extreme. Whenever it occurs, the rheumatism complicates.

Every gonorrhea patient sooner or later becomes lame in the knees, and it is a sure sign of the disorder when he or she is seen to limp. The treatment cannot be alkaline. Whether continued or intermitted, the alkalies do not avail. The preparation of guaiacum, or the compound decoction of guaiacum, into which guaiacum enters, has been found useful in some cases, but is not to be depended on. The Spanish treatment embraced inunction with mercurial ointment and mercurial fumigations. It is stated on what appears to be good authority that the Spanish physicians bled their patients, both locally and generally, and followed it with blisters. No wonder that it is told that "opium was also demanded."

Recently excellent results have been had from the use of eucalyptol, 2 drams with the same quantity of potassium citrate and 3 drams each of tincture of belladonna and mucilage of tragacanth. The dose is a teaspoonful every four hours. The physiologic effect seems to be exerted against the local affection. For the disinfection of the urinary tract the eucalyptus may be injected. A peculiar circumstance is the constipation attending the "malady of Manila." For this, elaterium has been used by the Spanish physicians to some extent, and is still in some favor. Somewhat oddly, the gonorrheal rheumatism is less severe during the rainy season.

THE URINE SEGREGATOR.

By M. L. HARRIS, M.D.,

Professor of Surgery, Chicago Polyclinic.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

DR. A. J. DOWNES, of Philadelphia, published in THE PHILADELPHIA MEDICAL JOURNAL of June 2, 1900, an article on what he terms "A New Instrument" for collecting the separate urines. The instrument presented is identical in principle with my segregator, and is the same in construction with the exception that he has omitted from his instrument a few little points which are present in mine and which are of so much importance that I deem it advisable to call attention to them again. Let us analyze the points which Dr. Downes claims for his instrument:

1. "A much smaller caliber as a whole." His measures No. 13 American, while mine is about a No. 24 French, the difference between these two being very slight.

2. "A simpler curve at the beak end." His is a simple arch which is continuous with the straight portion, while in mine the curve is set at a slight angular displacement with the straight portion, which permits the lever to hug closely the angle between the diverging ends when open, and allows for the thickness of the base of the bladder or tissues between the lever and the catheters. The distinct advantage of this is that it prevents the urine from running around the lever in the angle. A study of these two curves in the open bladder will show at once the superiority of the wide angle of my instrument.

3. "A single opening near the end of the beak." I had a single opening at first, but a study of different bladders showed that the ureters do not open always at the same distance from the internal orifice of the urethra, nor the same distance from each other. Consequently, when these distances are short the urine, after it escapes from the ureter, will have to come in contact with considerable of the bladder-wall before it can reach the end of the beak. The advantage, therefore, of multiple openings along the curve is apparent, as they permit the urine to enter the catheter at once as it escapes from the ureter, whether this opens near the urethra or far from it.

4. "The absence of a spring for elevating the partition." He sets his solid with a set screw. Experience shows that some bladders contract occasionally when the instrument is in place. The danger of injury to the bladder-wall is, therefore, much less when the parts are held together by soft, yielding springs, than when fixed solid by a set screw.

5. "The introduction of a new feature, siphonage alone, for the withdrawal of the individual urine," and 6. "The absence of all unnecessary suction apparatus" will be considered together.

Concerning the "new feature" of siphonage, in *The Northwestern Lancet* of November 15, 1898, I said: "As soon as the catheters and rubber tubing leading to the vials become filled it is seldom necessary to use the bulb as the urine usually flows by siphonage."

Again, in *The Medical Record* of April 1, 1899, I state "usually when the flow is once started, the dependent position of the vials and tubes produces sufficient siphonage to insure the immediate escape of the urine as soon as it leaves the ureters." It will be noted that it says "usually." At first it appeared the siphonage alone would be sufficient, but with more extended experience, a case was found now and then, in which the bladder would not empty itself completely with the patient on the back by the amount of

siphonage obtained. If such a bladder be filled with fluid and the instrument allowed to siphon it out, when the flow ceases, the use of the bulb will remove several ccs. more of fluid. I have seen several ccs. of urine accumulate in such a bladder with the instrument in place which would not flow until the bulb was used. I, therefore, called attention in the above-mentioned articles to the fact that while siphonage was usually sufficient an occasional case was found wherein the gentle use of the bulb was absolutely necessary to insure the immediate passage of the urine from the ureter into the catheter.

Those who have had much experience in this line would readily detect the points brought out, but as attention to detail is so necessary it was deemed advisable to present them again lest some fall into error. I wish also to protest against Downes' claim of a "new instrument," as there is nothing new in his instrument either in principle or method of use.

Fatal Case of Cocain Poisoning.—Henry Ernest Knight (*Quarterly Medical Journal*, for Yorkshire and adjoining counties, June, 1900) relates the case of a married woman of 22, 8 months advanced in pregnancy, who had been addicted to the use of cocain for about 2 years unknown to her physician and family. Her husband was awakened at 3 A.M. by hearing her fall and found her lying on the floor, unable to speak, and apparently unconscious, though the eyes looked at him vacantly. She was faint and cold, and blue about the lips. In a few minutes there was twitching of the face and both extremities, the breathing at first was good, but shortly became shallow, and death took place in about 15 minutes. A piece of paper labeled "cocain" and empty was found, and it was found that the patient had obtained 30 grains from a druggist the day before, and this she had evidently taken. The habit was begun by rubbing the drug on the gums for toothache and she had been taking on the average, at least 60 grains a day. The symptoms of the use of the drug—dizziness, nausea, and, at times, vomiting, dilated pupils, attacks of faintness, increased thirst, desire for stimulants, varying moods of temper—were masked by and mistaken for those due to her pregnant condition. It is estimated that death was due to at least 30 grains taken at one dose, although it is quite probable that more had been taken earlier in the evening. [M.B.T.]

Chronic Appendicitis and Intestinal Obstruction Necessitating Double Operative Intervention.—A. M. Cartledge (*Louisville Journal of Medicine and Surgery*, June, 1900). The history of the patient presented a number of attacks of appendicitis during the 2 years preceding date of operation, December 26, 1899. At operation the appendix was found adherent to omentum and intestines and with an abscess containing about one ounce of pus. It was removed entirely, and the omentum was fixed between the coils of intestine about the head of the cecum to prevent further intestinal adhesions if possible; stercoraceous vomiting, belching, and other symptoms of acute intestinal obstruction supervened within 38 hours, and a secondary operation was performed, an obstruction being found close to the ileocecal valve. March 10, 1900, the secondary operation for the cure of the obstruction was undertaken and about 4 inches below the original point of incision into the bowel, at the time of operation following appendectomy, the constriction was found, the bowel having a lumen not larger than a lead pencil; the adhesions were found very dense, and were dealt with in the usual manner. While the wound was on the long axis of the bowel it was somewhat oblique, and as the bowel was very much contracted and there was quite a large opening, a transverse suture was used instead of resecting the bowel and suturing. A small cheesy abscess found at the site of the appendix and head of the cecum was excised and drained; the intestine was carefully sutured, the drain wrapped in rubber tissue, carried out to the seat of this abscess and the balance of the wound closed by an interrupted silk wormgut suture. [M.B.T.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

The Lehigh County Medical Association met in Allentown, July 10. The following papers were read: "Cancer of the Stomach," by C. S. Martin; "Emphysema," by W. J. Lowright, and "Minor Surgery With Cases," by H. H. Riegel.

Lehigh Valley Medical Association.—The annual meeting of the Lehigh Valley Medical Association will be held at Neversink Mountain Hotel, near Reading, August 16. On invitation the Berks County Medical Society decided to meet at the same time and place.

Octogenarians in Quaker City.—An examination of the obituary records of Philadelphia for the first 6 months of the present year shows that during that period there have occurred the deaths of 493 persons who lived to or beyond the age of 80 years. Of these, 206 were men and 287 were women.

Hospitals Aided.—The following bequests are made according to the will of the late Henry M. Curry, of Pittsburgh, Pennsylvania. To the Western Pennsylvania Hospital, \$25,000, Pittsburgh Hospital for Children, \$20,000, Homeopathic Hospital, \$10,000, Western University of Pennsylvania, \$10,000, and to Kingsley Home, \$5,000.

Smallpox Quarantine Raised.—The smallpox quarantine on the houses in the block bounded by Fifth, Bristol and Lawrence streets, Philadelphia, has been raised. There were only 2 cases of the disease, and they recovered at the Municipal Hospital. The houses have been generally renovated under the direction of the Board of Health.

Baby-Farm in Philadelphia.—"Baulah Orphanage" is the name of a baby-farm in a six-roomed house on North Second Street, Philadelphia, where 13 children and 5 adults have been living at one time. The adults are members of a sect known as the "Fire-Baptized Holiness Association," and medicine is an unused factor in their lives. The death of a child, without medical attendance, revealed the peculiar state of affairs. The proprietors of the place have been sent to prison on the charge of criminal negligence and of conducting a baby-farm without a license, and will be held to await the action of the District Attorney.

The Public Bath Association of Philadelphia controls an institution for baths and family washing on Gaskill Street near Fourth and South. Fees: For a bath 5 cents, and 5 cents an hour for the use of family washing facilities. In 1898 one-third enough nickels were taken in to pay expenses, 1899 one-half enough, and this year they claim the receipts should reach 75%. The total number of bathers in 1899 was 34,680, of washers 1,487. Friends of the poor are asked to provide the additional \$5,000 needed. Contributions should be sent to the treasurer, Franklin B. Kirkbride.

The "Cripple News," is a unique periodical for a unique organization. The House of St. Michael and All Angels was founded September 29, 1886, and is located at 613 N. Forty-third Street, West Philadelphia, Pa., for the surgical treatment, and mental, religious, and industrial training of young colored cripples. It is the first known work of mercy devoted to crippled children of this race. This house receives destitute little colored cripples from any state or diocese, without entrance fee and without pay for board; it is without endowment (except 3 endowed cot-) or connection with any parish, and is entirely dependent upon charity.

Transportation of the Dead.—An Act concerning the transportation of dead human bodies across or within the State of New Jersey has recently been enacted by Senate and General Assembly of the State. It is not lawful for any person to convey or accept for transportation any human body dead of smallpox, diphtheria, scarlet fever, Asiatic cholera, yellow fever, typhus fever or bubonic plague except the same to be closed in a hermetically sealed casket and except a license for such transportation be obtained in writing from the Board of Health of the State of New Jersey.

Rules were also framed regulating the transportation, and forms of certificates and transits permits issued. Acts were also passed relating to burial and disinterment of the dead. Any person violating this law is liable to a fine of \$100.

The Medical Societies and "Divine Healers."—With a view of bringing within the scope of the law relating to the practice of medicine the numerous impostors who by posing as "Divine Healers," "Faith Curists," and other titles prey upon the credulity of their victims, the Philadelphia County Medical Society will at its next meeting discuss these humbugs and take steps to secure legislation which will compel these pretending healers and curists to register in the same manner as a regular practitioner and hold them responsible for any serious results arising from their methods. The laws of this State are not broad enough to punish "Divine Healers" and others of their ilk for the mere practice of their humbug, and they cannot be brought to justice unless their methods prove fatal to their patients or they are charged by one of their victims with having received money under false representations.

Vital Statistics of Philadelphia for the week ended July 14, 1900:

Disease.	Cases.	Deaths.
Total mortality		633
Inflammation of appendix 5, brain 13, bronchi 6, kidneys 15, heart 1, prostate gland 1, lungs 26, peritoneum 8, pleura 2, stomach and bowels 24, uterus 2, spine 2, tonsils 1		106
Cholera infantum 96, morbus 1		97
Inanition 18, marasmus 38, anemia 3, debility 7		66
Tuberculosis of lungs		65
Sunstroke		33
Apoplexy 21, paralysis 11		32
Heart—disease of 26, fatty degeneration of 4, neuralgia of 1		31
Uremia 18, diabetes 2, Bright's disease 5		25
Carcinoma of breast 3, bladder 1, colon 1, face 1, liver 5, mouth 1, rectum 1, stomach 5, throat 1, uterus 6		25
Convulsions		19
Diphtheria	56	17
Brain—softening of 7, congestion of 4, dropsy of 3, abscess of 1		15
Typhoid fever	27	11
Old age		10
Burns and scalds		7
Measles		7
Drowned		7
Teething		7
Diarrhea 4, dysentery 2		6
Suicide—hanging 1, illuminating gas 1, shooting 2		4
Cirrhosis of liver		4
Alcoholism		3
Cyanosis		3
Gangrene		3
Scarlet fever	33	3
Congestion of lungs 2, arterial sclerosis 2, surgical shock 2, whooping-cough 2, abscess of pelvis 1, aneurysm of aorta 1, erysipelas 1, goiter 1, hernia 1, homicide 1, influenza 1, obstruction of bowels 1, opium poisoning 1, purpura hemorrhagica 1, childbirth 1, suffocation by gas 1		

NEW YORK.

Coney Island Milk Inspected.—All places on Coney Island where milk and butter are sold were visited, July 12, by the State Dairy Inspectors, and several of the local health officials. Over 350 tests were made with only 6 suspicious cases.

Shoelaces in His Body.—Dr. Dwyer, of Passaic Hospital, has taken several yards of shoelaces from the body of a man who was in an explosion. The force of the explosion had driven the leather strings through the skin in two bunches, and they had traveled some distance between the ribs and the skin.

More Water for Brooklyn.—Filtering plants will be constructed at Springfield and Buisley's ponds by which 8,000,000 gallons of water daily will be added to Brooklyn's supply. It will require about two months' time to build the filters and at a cost of \$150,000.

Sterilized Milk for Brooklyn Babies.—The distribution of pasteurized modified milk for sick babies in Brooklyn began July 17. The preparation of the milk is conducted by the Board of Health. Arrangements were made with the matrons of the Brooklyn Diet Dispensaries and with hospitals for the distribution of the milk.

New York State Hospital for the Care of Crippled and Deformed Children.—The following, in addition to those already announced, have been appointed by the Consulting Board: Dr. Samuel B. Ward and Dr. A. Vander Veer, of Albany, Dr. Jarvis S. Wight and Dr. John A. McCorkle, of Brooklyn, and Dr. Richard B. Coutant, of Tarrytown.

Hospitals to Receive the Fayerweather Bequests.—In the United States Circuit Court, July 12, Judge Lacombe, of New York, handed down decisions in the Fayerweather will litigation, holding in favor of the beneficiaries, among which are the Presbyterian Hospital, St. Luke's Hospital, and Manhattan Eye and Ear Infirmary, with \$25,000 each, and the Woman's Hospital, and Mt. Sinai Hospital \$10,000 each.

Patent Medicine Cut-Rates.—An effort will be made to induce the retail druggists of New York to ratify the agreement made between the Retail Druggists' Association and the Manufacturers to keep the price of patent medicines up to the figures printed on their labels. If 75% of the retailers ratify this agreement in any locality, it is declared in force. A similar agreement as to the prices of patent medicines was formed by New York druggists in 1883 and proved ineffective.

New Milk Booths.—Two additional milk booths, erected under the supervision of the New York Park Department, have been completed and will be opened soon. Every facility for the proper care and dispensation of milk is provided. Free coupons have been issued by Mr. Straus to all charity organizations, the summer corps of doctors and others, and will be honored when presented at any of the 14 stations. During the hot weather filtered ice water will be furnished free from the booths in Central Park, City Hall, Tompkins' Square, and Battery Park.

Imperfect Sewer System.—The awards for damages for land to be taken at Jamaica South, L. I., for the erection of a sewage disposal works, have been confirmed. The Jamaica sewer system was built prior to consolidation, but the available appropriation was used up, and there were no funds for the city to build a disposal works. Frequently the sewers have flooded surrounding property, endangering health, and even at times approaching close to the stations of the Brooklyn water-supply system. The last Legislature passed a bill appropriating \$90,000 for the building of the plant. The work on the plant will begin soon.

NEW ENGLAND.

Typhoid in Connecticut.—An epidemic of typhoid fever at Forestville, Connecticut, has resulted thus far in 35 cases, and 6 deaths have been traced to a contaminated water-supply.

Yale Medical College.—Dr. Moses C. White, professor of pathology for the last 33 years, has become emeritus professor; Dr. Bartlett has been appointed to succeed him. Dr. Benjamin Moore, professor of physiology, has resigned, having been appointed to the lectureship in Charing Cross Hospital, London.

"Healer" Truth Free.—Francis Truth, the "healer," who was fined \$2,500 for fraudulent use of the mails, is now free. It is estimated that \$50,000 is in letters addressed to him at the post office. Now that Truth has pleaded guilty the postal authorities at Washington think the letters will be returned to the senders. He says that unless full reparation is made he will proceed against those who accused him of using electrical batteries and other artificial devices.

CHICAGO AND WESTERN STATES.

The Waukesha Medical Society.—The physicians of Waukesha, Wis., have formed a medical society.

Rush Medical College.—Dr. Daniel R. Brower has been appointed professor of neurology and psychiatry.

A Champion of Noise.—The Mayor of Chicago has vetoed the ordinance for the abolishment of unseemly noises in that city.

Smallpox at Chicago.—A victim of smallpox arrived in Chicago from Indianapolis recently and was taken in charge by the health department.

The Colorado State Medical Society held its thirteenth annual convention at Denver, June 19. The society now has 305 members. The next meeting will also be held in Denver. W. P. Munn was elected president.

Chicago's Streets Uncleaned.—The streets and alleys of Chicago are to be left uncleaned and the garbage uncollected because of a deficit in the city treasury. About 1,000 men have been discharged and all work on the streets stopped.

Smallpox at Fond du Lac and New London.—The demand of the health commissioners of Fond du Lac for a pesthouse revealed a case of smallpox in the city, and recently 4 deaths from the same disease were reported from New London.

College of Physicians and Surgeons.—The commencement exercises of the College of Physicians and Surgeons of San Francisco were held July 5. Degrees were conferred upon 33 graduates in medicine, 39 in dentistry and 9 in pharmacy.

Quarantine Hospital Closed.—The St. Louis Quarantine Hospital for the cure of smallpox and other infectious diseases has been closed for the summer, all the patients having been discharged as cured. In the season 108 cases have been treated at the institution with 2 deaths.

Postal Authorities Denounced.—"Dr." John A. Dowie, the self-styled divine healer and overseer of Zion congregation of Chicago, has in a sermon denounced the postal authorities for not admitting his new publication, the *Coming City*, to the mails at newspaper rates. The paper is devoted to the interests of "Dr." Dowie's real estate on the north shore.

Colorado State Medical Society.—The following will be the program for the entertainment of the visiting physicians to the Colorado State Medical Society: Smoker, Tuesday, 8.30 p.m., Champa Street, above 18th; Address on State Medicine (music if sufficient funds), Wednesday, 8.15 p.m., Brown Palace Hotel; Reception, Dance, and Banquet, Thursday, 8.30 p.m., Brown Palace Hotel.

Die Under Faith Cure.—Quarantined in a farmhouse near Rockville, Ill., with several of their companions dead and more than half of the survivors stricken with diphtheria, 25 followers of Abram Zook, a religious zealot, resist medical aid forced upon them by the authorities. The medicines left remain untasted by order of the leader, who believes in faith cure. Tar and feathers or lynching are suggested as the mildest punishment for such fanaticism.

Drought in Arizona.—It is reported from the drought-stricken sections of Arizona that every water hole and most of the wells have gone dry. In consequence, cattle are dying by the thousands and their shrunken frames dot the desert country of Pima, Pinal, Santa Cruz, Yuma, Cochise and parts of the Maricopa counties. Not a drop of water is reported in the Gila, and there is none in the San Pedro from Benson to its confluence with the Salt River above Phoenix. The prolonged drought has greatly augmented the sufferings of the famine-stricken Pima Indians on the Sacaton Reservation in Arizona. Most of the Indians now depend for food on the few who still have provisions. They are emaciated and suffering, and unless the \$33,000 Congressional appropriation can be used, private subscriptions must be taken.

St. Louis Water-test Fund.—The Council of St. Louis granted an appropriation of \$26,400 to complete the bacteriologic and chemic tests of the city's water-supply. The tests already made have proved that the water is unfit for use, but it is necessary to show by comparative daily analytic records whether it is more impure since the opening of the Chicago drainage canal than it was before. This is rendered necessary because of the proceedings of the city against the Sanitary District of Chicago.

Danger from Sewerage.—Chemist Bennett, of the Milwaukee Health Department, says that the objection to the outer harbor plan based upon the belief that an outer breakwater would tend to stagnate the sewage carried into the lake and gradually spread contamination far out from shore, is well taken. He believes that the currents in the lake are such, that this contaminated water would be carried out through the gap to the north and wafted almost directly in the vicinity of the intake, particularly when the wind is from the south or southwest.

Dr. Turck and the Humane Society.—Dr. Fenton B. Turck's researches in abdominal surgery have caused a general uprising among his neighbors in Chicago. The Humane Society has been notified. Dr. Turck does not deny the fact that he performs operations on dogs and other small animals, but says he works purely in the interest of humanity, and that he has been successful beyond hopes. The investigations were in gastroenterostomy. Dr. Turck's departure for Paris will probably settle matters without legal proceedings, which his neighbors threatened.

Practising without a License.—Dr. F. X. Schaeffer, of Milwaukee, was placed on trial in the police court recently on a charge of practising medicine without a license. He testified as to his practising medicine in the city prior to the passage of the law requiring physicians to take out a license. He then produced a diploma from the Wisconsin Eclectic College and a certificate to show that he had been a student at the university in Prague. He states that his diploma from this university was destroyed by fire in Cleveland. The case will come up again later.

Unsanitary Conditions in San Francisco.—A complaint was made recently to the Board of Health of San Francisco against the Bryant Street sewer and its terminus. The attention of the Board of Supervisors will be called to the unsanitary condition of the locality. An ordinance prohibiting the renting or occupancy of lower portions of the apartments of any building the floors of which are damp or impregnated by any offensive gas injurious to health; also prohibiting the occupancy of cellars, bathrooms, or rooms containing a vault, or other places that are dangerous to life or health by reason of a want of ventilation or drainage, was submitted to the Board of Supervisors.

A New Diploma Mill.—The Secretary of State recently chartered a concern in Chicago under the title "The Chicago College of Medicine, Surgery, and Hygiene." The attention of the State Board of Health is now called to the corporation. The certificate of incorporation gives the purpose of the College in the following language: "For the purpose of training students in the science of life, hygiene, and sanitary science, and the care of the body in sickness and in health, and for instructing and training in physical development to fulness of health, beauty, and attractiveness; and for the correction of habits and modes of living tending to shorten life and making chronic invalids; and for special instructions how to live 100 years or more in good health; and to confer degrees and grant diplomas." This institution has no standing in the knowledge of the Board of Health.

SOUTHERN STATES.

The Mississippi Valley Medical Association will hold its twenty-sixth annual meeting at Asheville, N. C., October 9, 10, 11, 1900, under the presidency of Harold N. Moyer, of Chicago.

Johns Hopkins University.—Dr. W. H. Welch has been appointed professor of therapeutics and materia medica, and O. to G. Ramsay has been appointed to the chair of obstetrics and gynecology.

Deaths of Children in Baltimore.—There were 171 deaths of children under 5 years of age, and 148 of children under 1 year of age for the week ended July 14. Inanition caused 21 deaths and cholera infantum 99.

Texas Quarantines.—In case quarantine is declared against New Orleans, Texas will admit lime, stone, cement, turpentine, rosin, coke, machinery, iron, tin, steel, sugar, molasses, rice, fruits, sound and taken direct from clean vessels that have complied with all quarantine regulations; all articles to be in straight carload lots, freights and cars to be disinfected when deemed necessary by the State health officer. Through freights and freights originating in New Orleans destined to points beyond Texas will be permitted to pass when complying with proper restrictions. All railroads must agree to the terms set out, and if they violate the agreement they will forfeit all right to bring freight into Texas.

MISCELLANY.

Serum Treatment.—Dr. Bellinzaghi, of Brazil has brought his yellow-fever serum to the hospitals of Vera Cruz for trial. Governor Desha has appointed a committee of doctors to aid him in his work.

Smallpox at Cape Nome.—A dispatch announces 20 cases of smallpox isolated at Cape Nome. The steamer St. Paul arriving at San Francisco also reports many cases of typhoid fever and smallpox at the Cape.

Yellow Fever.—The yellow fever at Quemados has probably reached an end. No new cases have been reported since July 1, when Major Surgeon Ducker, the noted yellow fever expert, was stricken with the disease.

Marine-Hospital Service.—Surgeon Milton J. Rose-nau will represent the service at the International Medical Congress in Paris, commencing July 29, and Assistant Surgeon Samuel B. Grubbs will be the representative at the Congress of Applied Chemistry, held in Paris, July 23.

A Mode of Quenching Thirst.—Thirst disappears and perspiration is diminished by keeping a small round pebble in the mouth, according to Dr. A. Philip. He states that he has gone as long as 8½ hours in a broiling sun with nothing but dry biscuits and cheese for a lunch, and at the end of that time was not particularly thirsty.

German Meat Bill Modified.—The German Government has consented to modify the new Meat Inspection Bill so that it will not interfere with existing contract obligations of American exporters. All present contracts will be carried out on the present basis of inspection, and the new system will apply after there has been opportunity to make contracts with the full knowledge of the changed conditions of affairs.

Obituary.—DAVID G. BOWMAN, of Denton, Md., aged 63.—CHARLES F. McDONALD, of Hamilton, Ont., aged 71.—DAVID P. WOLHAUPT, of Washington, D. C., July 11, aged 61.—CHARLES P. JUDKINS, of Cincinnati, July 1, aged 57.—GERALD FREEMAN, lost overboard in Halifax Harbor, July 6.—FRANKLIN GAUNTT, of Burlington, N. J., July 7, aged 77.—JOHN B. CHAMBERLAIN, of Moss Point, Miss., on July 13, aged 35.—K. D. COLLINS, of Point Coupee Parish, July 12, aged 30.—SAMUEL RUSSELL WELLS, of Waterloo, N. Y., aged 75.—T. H. B. DILLARD, of Salem, July 13, aged 71.—ROBERT JACKSON HILL, of St. Louis, July 15, aged 64.—THOMAS WELSH, of Davidsonville, Md., July 16, aged 61.

The Red Cross.—A meeting of the incorporators of the Red Cross was held in Washington, July 10. Miss Clara Barton was again elected president. The act of incorporation sets forth that, at Geneva, representatives of Italy, Baden, Belgium, Denmark, Spain, Portugal, France, Prussia, Saxony, and Württemberg, and the federal council of Switzerland agreed upon articles of a convention for mitigating the evils of war, and providing for a distinctive flag for wounded and neutrals. This treaty was ratified by 43 nations, including the United States, and a permanent organization formed for the purpose of cooperating with the international committee. The act gives the corporation right to hold real estate, to sue and be sued, and to use the Greek cross, which was adopted by the several nations.

Maritime Quarantine at Cape Nome.—The Surgeon-General of the Marine Hospital Service has ordered Assistant-Surgeon Earle, of the Marine Hospital, San Francisco, California, to take the first available steamer either from San Francisco or Seattle for Cape Nome, to confer with Lieutenant Jarvis, who has established a quarantine, and to arrange with him and with General Randall for maintaining maritime quarantine. Before going he was ordered to confer with Kinyoun as to quantity of sulphur and bichlorid and number of Dutch ovens or pots of fumigation needed, and order same and ship by the speediest practicable route. The government will mail from Washington 5,000 vaccinations unless he can purchase good virus in San Francisco, in which case he is to purchase and take with him. If possible he is to extend shore aid to the extent of vaccinations.

Patent Medicine Indorsement by the Ministry.—Labor Commissioner Carroll D. Wright, speaking as to the result of an investigation of the liquor question by a committee of which he was a member, said that one of the most comical conclusions reached already is the amount of alcohol there is in the widely-advertised patent medicines. The truth in this regard has been published many times, he said, but the people do not seem to take it to heart, and keep on buying the nostrums which are sometimes worse than harmless. He laughed heartily as he told of prominent W. C. T. U. leaders who preached 7 days and 7 nights a week against the sin of intemperance and then wrote long and enthusiastic testimonials for some patent medicine telling how it had given them new life and taken away that tired feeling and braced them up from day to day for the day's arduous work; and of Methodist ministers who cried down the crime of indulging in strong drink, recommending to their friends some patent medicine or invigorator or tonic which had done them a world of good and made new men of them two or three times a day. "Of course it had," said Mr. Wright. "They were under the influence of alcoholic stimulant. Some of those patent tonics have as high as 25 and 30% of alcohol, and champagne has less than 10% of that stimulating drug. They were drunk when they were recommending the stuff and talking against intemperance." —[*Evening Wisconsinian*]

Changes in the Medical Corps of the U. S. Army for the week ended July 14, 1900:

POLHEMUS, Captain A. S., assistant surgeon, now at the Presidio, will rejoin his proper station, Fort Leavenworth.
BOWMAN, MADISON H., acting assistant surgeon, are relieved from temporary duty at the U. S. general hospital, Presidio, and will report to the commanding officer, Sixth Cavalry, for duty with that regiment.
HALSELL, JOHN T., acting assistant surgeon, are relieved from temporary duty at the U. S. general hospital, Presidio, and will report to the commanding officer, Sixth Cavalry, for duty with that regiment.
DICKINSON, CLARENCE F., acting assistant surgeon, is assigned to temporary duty with troops on the U. S. transport "Grant," to sail for the Philippine Islands about July 1.
VAN KIRK, HARRY H., acting assistant surgeon, is assigned to temporary duty with troops on the "Grant," to sail for the Philippine Islands about July 7.
JENKINS, FREDERICK E., acting assistant surgeon, is relieved from temporary duty at the U. S. general hospital, Presidio, and assigned to temporary duty with troops on the transport "Conemaugh," during the voyage of that vessel to the Philippine Islands.
ROWAN, CHARLES J., acting assistant surgeon, is relieved from temporary duty at the U. S. general hospital, Presidio, and assigned to temporary duty with troops on the transport "Leclanaw," during the voyage of that vessel to the Philippine Islands.
LUNDY, PEMBERTON, acting assistant surgeon, is relieved from duty in the division of Cuba, and will proceed to Buffalo, N. Y., and report by letter to the Surgeon-General of the Army for annulment of contract.
CLAYTON, First Lieutenant JERE B., assistant surgeon, will proceed from Vancouver Barracks to Portland, Oreg., and make a thorough sanitary inspection of the U. S. transport "Lennox."
STEPHENSON, Major WM., surgeon, having completed the duty for which he was ordered to Washington, D. C., will return to New York City.
GOLTRA, J. N., acting assistant surgeon, is granted leave for 20 days.
CUSHMAN, GABRIEL, hospital steward (appointed June 30, from acting hospital steward, hospital corps), now at Skagway, Alaska, is assigned to duty at that post.
BALCH, Major LOTIS, surgeon, is granted leave for 1 month on account of sickness.
VON CLOSSMAN, AUGUST, acting assistant surgeon, is relieved from duty at Jefferson Barracks, and will proceed to St. Louis for

duty as attending surgeon and examiner of recruits in that city.

BUNGER, HENRY, hospital steward, Fort D. A. Russel, orders which direct him to be sent to San Francisco, Cal., en route to the Philippines, is revoked.

GIESERING, FRED., hospital steward, Fort D. A. Russell, will be sent to Fort Logan for duty.

JOHNSON, DAVID J., acting assistant surgeon, will report to the commanding officer, Fifteenth Infantry, for duty to accompany the first battalion of that regiment from Plattsburg Barracks to San Francisco, and upon the completion of this duty will return to his proper station.

MAHON, A. N., acting assistant surgeon, is granted leave for 20 days.
MCKAY, JAMES G., acting assistant surgeon, leave granted to him is extended 20 days.

WOODHURY, FRANK T., acting assistant surgeon, will proceed from Philadelphia, Pa., via San Francisco, Cal., to Manila, P. I., and report to the commanding general, division of the Philippines, for assignment to duty.

SHIMER, First Lieutenant IRA A., assistant surgeon, leave granted to him is extended 1 month.

GRIFFITH, LEWIS T., acting assistant surgeon, is granted leave for 15 days to take effect on his being relieved from duty at Fort Preble.

A board of officers to consist of Colonel WILLIAM H. FORWARD, assistant surgeon general; Major WILLIAM H. ARTHUR, surgeon, is appointed to meet at San Francisco, Cal., to examine into and report upon the physical fitness of First Lieutenant JOHN CROTTY, Fortieth Infantry, U. S. Volunteers, to perform the duties of his rank.

A board of officers to consist of Lieutenant-Colonel BENJAMIN F. POPE, deputy surgeon general; Captain HENRY A. SHAW, assistant surgeon, First Lieutenant HENRY E. WETHERILL, assistant surgeon, is appointed to meet at the Presidio, June 25, to examine into and report upon the present physical condition and fitness to remain in service of Major LEWIS BALCH, surgeon.

Changes in the U. S. Marine-Hospital Service, for the week ended July 12, 1900:

STONER, G. W., surgeon, is granted leave of absence for 5 days.
GLENNAN, A. H., surgeon, is detailed as quarantine officer at the port of Havana, Cuba, vice Surgeon H. R. CARTER, relieved.
WASDIN, EUGENE, surgeon, is granted leave of absence for 10 days.
WILLIAMS, L. L., surgeon, is detailed as acting medical purveyor during the absence of leave of Surgeon G. W. Stoner.
MCINTOSH, W. P., surgeon, is granted extension of leave of absence for 2 days.
BLUE, RUFERT, passed assistant surgeon, directed to proceed to Milwaukee, Wis., and assume command of the service, reporting at Washington, D. C., en route.
SPRAGUE, E. K., passed assistant surgeon, is granted leave of absence for 2 days.
GRUBBS, S. B., assistant surgeon, is detailed to represent the service at the fortieth session of the International Congress of Applied Chemistry at Paris, France, July 23-31.
BILLINGS, W. C., assistant surgeon, is relieved from duty at Washington, D. C., and upon expiration of leave of absence to proceed to Baltimore, Md., and report to medical officer in command for duty and assignment to quarters.
KEER, J. W., assistant surgeon, is relieved from temporary duty at San Francisco quarantine and directed to proceed to Honolulu, H. I., and report to Surgeon Carmichael for duty.
THORNBURY, F. J., assistant surgeon, on return of Passed Assistant Surgeon C. H. Gardner from leave of absence, to proceed to Chicago, Ill., and report to medical officer in command for duty and assignment to quarters.
VOGEL, C. W., assistant surgeon, is relieved from duty at San Francisco Quarantine and directed to proceed to San Francisco and report to medical officer in command for duty and assignment to quarters.
GLOVER, M. W., assistant surgeon, on being relieved from duty at Baltimore, Md., directed to proceed to Boston, Mass., and report to medical officer in command for duty and assignment to quarters.
EARLE, B. H., assistant surgeon, is directed to proceed to Cape Nome, Alaska, for special temporary duty.
PIERCE, C. C., assistant surgeon, is relieved from duty at Mobile, Ala., and directed to proceed to Tortugas Quarantine and report to medical officer in command for duty and assignment to quarters.
GIBSON, L. P., acting assistant surgeon, is granted leave of absence for 5 days.
GREENSTREET, A. G., of the District of Columbia, appointed acting assistant surgeon for duty at Wilmington, N. C.

Changes in the Medical Corps of the U. S. Navy, for the week ended July 14, 1900:

OLEOTT, F. W., passed assistant surgeon, detached from the Recruiting Rendezvous, Philadelphia, Pa., and ordered home and granted sick leave for 2 months.
GROVE, W. B., passed assistant surgeon, detached from the "Scindia" and ordered home.
RESN, W. H., surgeon, granted sick leave until October 1.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended July 14, 1900:

SMALLPOX—UNITED STATES.

DISTRICT OF	CASES.	DEATHS.
COLUMBIA: Washington . . . July 1-7	4

Treatment of Scoliosis.—Hoffa gives (*Zt. f. Orthop. Chir.*, vol. vii, p. 535) the following suggestions as essential: (1) The stiff scoliotic spine must be made pliable; (2) the muscles of the back should be strengthened by active exercise so that they are able to overcorrect the deformity, and this can be done in all except the worst cases; (3) the position thus attained is to be kept by proper apparatus. The motions used in the exercises consist in stretching the back upward, thereby assuming the "best possible posture," bending at the hips while the back is still stretched, in placing the hand on the side of the convexity of the main curve on the ribs of that side and exerting pressure, in placing the hands over the head and tilting the pelvis by bending one knee and in various combinations of these movements. A stationary apparatus, which helps the patient to make these movements properly, and a portable supporting jacket which holds the back in a normal position are described and illustrated. [G.B.W.]

Foreign News and Notes.

GREAT BRITAIN.

New Medical Deputy Lieutenant.—The appointment has been announced of Dr. Joseph Byrne, of Londonderry, as deputy lieutenant of the city and county of Londonderry.

New Asylum at Hollymoor.—An inquiry under the auspices of the Local Government Board was held on June 21 for the purpose of borrowing £219,250 for building a new asylum at Hollymoor.

Cremation.—Lord Monkswell's Bill has passed through Committee in the Lords. It is now called the Cremation Bill, 1900. It has been amended so as to widen its scope, and bring under Home Office regulations private crematoria as well as those conducted by public authorities.

Prof. Ogston Ill.—Much regret is felt in Aberdeen at the fact of Professor Ogston being ill with fever at Bloemfontein Hospital. Professor Ogston was no doubt exposed more to infection than other acting army surgeons, as he was not attached to any particular hospital but took a general survey of the medical arrangements at the seat of war in South Africa.

The St. Pancras Scandals.—An inquiry into the irregularities in connection with the certification of lunatics in St. Pancras has been ordered. Mr. Chaplin stated that there was reason to believe that the system was more or less widely practised elsewhere in the metropolis. The guardians had been informed that the Local Government Board regarded the practices complained of as altogether indefensible, and any officer offending in this respect in the future should be dismissed.

Antityphoid Inoculation.—A. Conan Doyle believes that a mistake has been made in not making the inoculation for typhoid compulsory among the soldiers in South Africa. In a letter to the *British Medical Journal*, he says: "We have no doubt the matter will be fully threshed out in statistics, but our strong impression, from our own experience, is that although it is by no means an absolute preventive it certainly modifies the course of the disease very materially. We have had no death yet from among the inoculated, and more than once we have diagnosed the inoculation from the temperature-chart before being informed of it. Of our own personnel only one inoculated man has had it, and his case was certainly modified very favorably by the inoculation."

Factors Leading to a Relatively High Percentage of Male Offspring.—After studying more than 300 marriages with the object of discovering some of the conditions likely to give rise to a relatively high percentage of boys, Dr. Gerald S. Walton has come to the following conclusions: 1. Do not marry the eldest daughter of a family, but rather the youngest. There is a progressive increase of boy-producing power from the eldest up to the youngest daughter. 2. Do not marry one whose age differs much from your own, and do not marry much under or over 30. 3. Do not marry a widow. 4. Do not refuse to marry a cousin or an only daughter. He thinks if these rules are followed we will hear less often the complaint of paterfamilias that he has "seven daughters who prophesy," and, alas, not one son.

Purity of Drugs.—*The Physician and Surgeon* says that medical men do not, as a rule, obtain warranties with the purchase of their drugs. Beyond the words on a label or an invoice, they have no written assurance from the wholesale druggist who supplies them with medicaments that the latter are up to the standard. The druggist could not, therefore, be sued under the Food and Drugs Acts for the sale of defective preparations unless the medical man had taken some most unusual trouble when he made his purchase. But it now appears that loss or damage can be recovered in Great Britain in these circumstances on the ground that an implied warranty has been given. At any rate, a person who was supplied with defective camphorated oil which was not specifically guaranteed as of B. P. quality, has been able to recover from the wholesale supplier penalties which were incurred through the sale of this article to the public.

Lack of Medical Attention in South Africa.—J. J. Van Alen, of New York, who equipped an ambulance corps and hospital for field service in South Africa, which the British Government finally accepted, referring to the charges made against the British army hospital corps in the field, said the charges were true. With Roberts' army men died of typhoid from lack of attention. Near Bloemfontein two marquees and a few bell tents contained 496 patients, 300 typhoids. There were only 17 orderlies to attend to what is within 24 of the number allotted to a general hospital. Mr. Van Alen thought the cause of such a condition was due not so much to the personnel of the army medical corps as to the sudden and unexpected amount of sickness at the front. The army with Roberts, in the face of their heavy marches, had outstripped the medical corps, and although supplies were abundant, the surgeons did not expect an epidemic of typhoid, and were unprepared.

The Light-Treatment in London.—On June 30, Mr. Malcolm Morris, of St. Mary's Hospital, gave a demonstration of the electric light treatment of lupus and other superficial skin-diseases to members of the Medical Graduates' College and Polyclinic. He pointed out that a great advance was made when the plan of scraping lupoid tissue with a Volkmann's spoon was adopted, and spoke of points in technic and factors in the success with light-treatment. A good instance of the difficulty experienced was in cases of lupus of the cheek implicating the interior of the nose. In such cases a combined method of treatment with the Finsen light and the x-rays had given excellent results. Its *rationale* is that, as the Finsen rays cannot be brought to bear on any other than plane surfaces, the Röntgen-rays, in virtue of their power of penetrating soft tissues, may be used to act on mucous membranes, however complicated their arrangement. After about 15 or 16 exposures, a distinct improvement was manifest. The reaction produced was similar in kind to that of the Finsen system, but the dermatitis which was set up was said to be less marked in diseased tissues than in healthy ones.

CONTINENTAL EUROPE.

Resort for Invalids.—A day resort for pulmonary invalids has been opened on the outskirts of Berlin, with facilities for reclining, warming lunches, and obtaining inexpensive wholesome refreshments.

New School for Nurses in Russia.—The first meeting of the committee of the Russian Red Cross for the organization of a school for female nurses was held April 23. It will probably be established at Wassili-Ostroff in connection with the hospital.

Food Adulteration in Europe is attracting the attention of the authorities, especially in Switzerland. Chocolate and honey are frequently adulterated and the weight of bread increased by the introduction of ingredients that lessen its nourishing powers. Artificial coffee-berries have been so well made by the aid of some agglutinant that the deception was not discovered for a long time. The Chinese frequently mix sage, linden, strawberry and other leaves with tea or the leaves of brewed tea have been used for export trade.

Foreign University Intelligence.—Dr. A. Birnbacher, extraordinary professor of ophthalmology at Gratz, has been appointed ordinary professor. An institute of forensic medicine has been recently established at Leipsic, the charge of which has been intrusted to Professor Kockel. Dr. Calmette has been appointed professor of hygiene and bacteriology at Lille. Dr. Ernesto Tricoma, of Padua, has been appointed professor of clinical surgery and operative medicine at Messina. Dr. Bosc has been appointed professor of pathologic anatomy at Montpellier. The chair of systematic medicine in the University of Glasgow, vacated by the resignation of Sir William Gairdner, has been filled by the appointment of Professor McCall Anderson.

Leprosy in Portugal.—Dr. Zepherino Falcao has presented to the Royal Academy of Sciences at Lisbon a communication on the extension of leprosy in Portugal. Since the suppression of leper houses in that country the disease has gradually spread, and it is estimated that there are now

some 1,500 lepers in the country; this is a considerable proportion in a population of 4,700,000. The lepers are scattered throughout the country, no district being exempt; most of them, however, are on the coast and in the deep valleys. There are, however, also foci in the mountain regions. Dr. Falcao considers that the disease as it is met with in Portugal is very slightly contagious, special conditions being necessary for transmission to take place from one patient to another. —[*British Medical Journal*.]

MISCELLANY.

Danger of Pestilence.—A cablegram from Tien Tsin states that 10,000 Chinese have been killed in the attack and lie unburied outside of the city. The food-supply of the besieged is also short.

Plague.—A fatal case of plague, according to private advices, occurred recently on board the *Isla de Luzon*. The patient was an Asiatic and was concealed for several days before discovery of his ailment.

Women Doctors in the East.—The Hon. Ella Scarlett has recently sailed for Korea to take up an appointment as physician to the women of the Royal household at Seoul. She will assist Miss Cook, who has been attached to the Court for some years.

Mortality of Typhoid.—It was stated in the House of Commons, June 29, that the percentage of mortality in typhoid cases during the South African war, and more especially at Bloemfontein, has been 21 of the admissions to hospitals. The total number of admissions for typhoid fever at Bloemfontein for the 8 weeks ended May 11, was 2,087, with 286 deaths. The total admissions for simple continued fever were 5,860, with only 1 death.

Calcium Chlorid in Plague Inoculation.—An interesting report on the Hallkine prophylactic has been submitted by Captain Stevenson. Among other points he refers to the effect of calcium chlorid on the febrile reaction and shows that given both before and after the inoculations it has a good effect. The best results were obtained when the calcium chlorid was given a few days before the inoculation as well as after it.—[*Lancet*.]

Leeches in the Philippines.—A correspondent writing from Paete, P. I., speaks of the land leeches which got on the soldiers. They even crawl through the lace-holes in the shoes and under the leggings. Everywhere they bite the blood keeps up a continuous flow. After being out 5 days and 4 nights among the leeches, the men looked as though they had been shot full of holes, for their clothes were covered with blood. In comparison with them the mosquito is a harmless thing.

A Curious Dental Accident.—The *Indian Medical Record* of June 6 reports a curious accident. A boy, aged 9, while driving a cow was horned by her in the face. The effect of the blow was to drive the left central incisor through the alveolar process into the incisor fossa, from which it was easily removed by means of suitable forceps. The remarkable features about the accident was that the blow inflicted no other injury in the mouth. The tip of the horn must just have caught the cutting edge of the incisor tooth.

Cholera and Famine.—The Secretary of State for India, Lord George Hamilton, has received the following from the Viceroy of India: "The cholera mortality continues high in Bombay. The May mortality there was appalling. The number of persons receiving relief is 6,013,000." The Governor of Bombay telegraphs to the Foreign Office: "There were 10,320 deaths from cholera and 6,502 fatalities in the famine district during the last week in June. The total deaths among the numbers on the relief works in the British district were 5,324."

The Native Manila Bed.—Lieut. Fred. T. Austin, 46th Vol. Inf., writing home from Manila to the *Reveille* tells us of his first experience with a native bed. "It has," he says, "the advantage of hanging high enough from the ground to prevent the lizards from crawling down the back of our necks and the bugs and ants from using us as a promenade."

We have seldom used the hammocks in the field as we were not able to carry them. We have become used to the lizards and other crawling things of the tropical jungles, but no words can describe these little ants. They are found everywhere by millions, on the hard tack and in the coffee. At night they seem to take a fiendish delight in marching up and down the back of one's neck."

Obituary.—PROFESSOR DANIEL JOHN LEECH, of Manchester, aged 60.—DENNIS CAWOOD EMBLETON, of Bournemouth, June 18, aged 46.—ROBERT ARGLES, of Hyde Park, June 14, aged 60.—CADET DE GASSICOURT, of Paris, aged 74.—JAMES ALEXANDER BAIRD, of Dublin, June 29 aged 44.—ARNOLD SCHETELIG, of Nervi, aged 65.—JAMES STEVENSON FORRESTER, on board the *Dunera*, June 18.—W. H. F. RAMSDEN, of Saddleworth, June 24.—THOMAS McLAUGHLAN BROWN, of Glasgow.—DR. CHÉRON, of Paris.—HENRY BURFORD NORMAN, of Chesham, June 11, aged 81.—HENRY PEACOCK, of Bath, June 12, aged 88.—ARCHIBALD ADAMS, of the Indian Medical Service, at Mount Abu, May 20, aged 50.—CLAUDE CLARKE CLAREMONT, at Bognor, May 27, aged 77.

Prof. Koch's Investigations on Malaria.—The report from Stephansort, New Guinea, states that through the efforts of the members of the German Malarial Expedition malaria has been reduced to a minimum in that place. The same measures are used for the purpose of prophylaxis as for treatment. A number of Ambonese, a people very susceptible to malaria, came to Friedrich-Wilhelmshafen. About one-half of them took quinin prophylactically while the other half did not. The former group remained well; of the latter, all fell ill of malaria with the exception of one woman. They were sent to Stephansort for treatment, where they quickly recovered. The members of the expedition have regularly carried out the prophylactic use of quinin and have for 4 months remained free from malaria. Prof. Koch believes that in the future a greater effort will be made to destroy the malarial parasite. The less infective material there is about the less will be the need of quinin prophylaxis. He speaks of many chronic and mild cases, the diagnosis of which can only be made by the use of the microscope; these cases frequently do not seek medical aid. He says that to suppress malaria will be a tedious undertaking, but we are in a position to make every malarious district wholly or nearly free from malaria. The only requisites are the necessary number of doctors and a sufficient supply of quinin. In the case of an intelligent and obedient population it will not be difficult to carry the struggle against malaria to a successful issue.

The Famine in India.—Dr. Louis Klopsch, who went to India to prepare the way for the arrival of the *Quito*, chartered by the United States Government to carry 200,000 bushels of grain to Bombay, has returned to New York. He says the grain is sold at 75 cents a bushel to those famine sufferers who have money. It cost 50 cents a bushel. The profit is to be used to buy grain for those that have absolutely no means. He also said there was plenty of grain in India, but it was sold at high prices. He said that famine sufferers increase at the rate of 25,000 a day. As soon as the rainy season sets in he fears the plague will find every condition favorable for development. In large districts of India millions of cattle could not be sold for 50 cents a head. The country has been turned into a desert by the failure of the monsoon rains. There are grass lands in other parts of India, but the animals are too weak to be driven to them. The thought has never occurred to the 35,000,000 Hindu peasantry now suffering from hunger that the cattle would have been a food-resource to tide them over the months of crop-failure. The people who base their religious beliefs upon the Vedas would rather swallow dirt and gnaw roots than eat beef, and yet they are not strict vegetarians, for all eat butter and milk, and also fish and mutton when they can procure them. Beef is proscribed for food. In this vast region no meats are imported except for European consumption. If there is a partial failure of rice, wheat, maize, barley or the indigenous grains on which the laborer lives, starvation begins at once; and so while India sells to the world every year from \$250,000,000 to \$350,000,000 worth of products, and buys about three-fourths as much as she sells, her purchases are almost wholly textiles, machinery, railroad material and coal.

2.—Mott says that secondary Wallerian degeneration conclusively proves that the reciprocal metabolic interaction of the axon and its ensheathing structures is controlled by the nerve-cell and its contained nucleus. The nerve being cut the axon and myelin sheath die, but the substance of Schwann does not. The latter doubtless plays an important role in regeneration, as regeneration in the central nervous system, where the substance of Schwann is absent, does not occur. When a nerve is injured its cell-nucleus is seen to undergo: (1) The reaction phase; (2) the reparation phase, during which the cell increases in volume; and (3) if the injury be so severe that regeneration cannot take place, the degeneration phase. The author distinguished diseases of the nervous system from diseases within the nervous system. Cutting off of blood-supply to the central nervous system leads to cell-changes, and death soon follows; but if the anemia die but temporary there may be only loss of consciousness, etc. Thus we can understand how temporary loss of motion or psychical functions may occur in syphilitic disease of the arteries; for if collateral circulation be restored within an hour or so after blocking of the artery, the function may be restored in the course of a few hours or days. In producing anemia of the spinal cord experimentally by clamping the abdominal arteries, in animals, it was found that the exogenous fibers of the posterior columns and the pyramidal tracts, which have their origin respectively in the spinal ganglia and the cerebral cortex, do not undergo degeneration, but the tracts which have their trophic and genetic centers in the cells of the gray matter of the cord undergo degeneration. Mott cites a case of acute anterior poliomyelitis occurring in an infant. Examination was made 14 days after the onset, and the degeneration was limited entirely to those tracts, the fibers of which arise from cells in the cord. He is of opinion that spasm of the large artery supplying the lower end of the cord caused a cutting off of the blood-supply, and consequent degeneration of the cells giving origin to these fibers. Among the insane he found that among those who suffered from epileptic attacks the frequency and severity of the paroxysms varied in proportion to the large number of recently degenerated fibers of the pyramidal systems. Consequently we may assume that elephiform seizures in this disease are associated with death of the cortical pyramidal motor neurons, due in great measure to vascular disturbance of the cortex. The disease is primarily a progressive decay of the nervous elements, but owing to circulatory disturbances large numbers of neurons are destroyed, and thus the seizures precipitated. The arteries are seldom occluded in general paralysis, but congestive stasis in the arterioles, capillaries, and veins, and even thrombosis in the latter is common. Destruction of the nervous cortex is probably accelerated by this inflammatory stasis. The brain atrophy in this disease is usually limited to the frontal and central convolutions. Over this region the pia-arachnoid is thickened and adherent. This area is drained largely by those veins emptying into the longitudinal sinus, and the author is of opinion that venous stasis plays a large part in the symptomatology and pathology of this disease. Hyperpyrexia induces a swelling and coagulation of the nerve-cells in the gray matter of the

spinal cord; a temperature of 107° F. continued for some hours in the rabbit effected the same change as 109.5° F. for a short time. If the temperature is soon reduced the animal recovers. The author thinks this explains the remission of symptoms, the return of consciousness, and recovery, which often takes place in some forms of hyperpyrexia when the cold bath method is resorted to without delay. The influence of the toxic conditions of blood and lymph upon the nervous system, and the selective influence of poisons are considered by the author. [A.B.C.]

3.—Ransom gives in detail the history and treatment of 6 cases of lead poisoning due to the use of **diachylon as an abortifacient**. The poison symptoms became manifest in from 6 months to a year or longer after taking the drug. The dose taken varied from a halfpennyworth to a pennyworth (23 to 46 grains) taken in 1 or 2 doses. It terminated the pregnancy in every one of his cases after longer or shorter period. The writer has obtained literature on the subject from various men of note and has come to the conclusion that it is without doubt that diachylon is largely used for abortion. It is easily purchased. Penny balls of the emplastrum plumbi are kept by the most respectable chemists ready wrapped in a handy drawer; there is absolutely no restriction on its sale. For a penny a woman can buy enough lead to not only empty the uterus but to cause grave disease of the bowels, the kidneys, and the brain; a disease which not rarely proves fatal. The drug proves to be an insufficient abortifacient, always endangers and often destroys life or leaves permanent bodily and mental enfeeblement. It is a question whether something should not be done to restrict the indiscriminate sale of this drug and to class it with poison. [A.B.C.]

4.—Ward reports an interesting case of specific hyperostosis of the skull occurring in a boy 6 years of age and operated on by a method closely resembling **Lannelongue's craniectomy**. A skin-flap 2½ inches in width and the whole length of the skull was turned upward and a piece of bone ½ inch in width was chiseled out from the skull the whole length of the cutaneous flap. The patient made great improvement after the operation, and was almost free from his old symptoms except that he had lost the power of his legs. But about 5 months later he was suddenly taken with a fit and died before help could be summoned. [G.B.W.]

5.—Petyt reports a case in which a **pin was introduced into the ear** for the purpose of removing cerumen from which there had been otorrhea for some years and the pin slipped into the ear, thence to the throat where the patient felt it sticking, but before it could be removed it passed on into the stomach, and 3 days later it passed the anus. [A.B.C.]

6.—Wightman reports a case of **ossification of the stylo-hyoid ligament** simulating a foreign body. The patient complained of having a piece of rabbit bone lodged in his throat. Upon examination he found no laceration of the mucous membrane, but felt a hard elongated mass on the left side of the pharynx behind and slightly below the posterior pillar of the fauces. [A.B.C.]

7.—Reid mounts **mosquitos, aphides, etc.**, in glycerin. He coaxes them into a drop of the glycerin and allows them to get entangled into it and then with fine needles puts them into the most advantageous position. He claims that this method prevents their being injured and the air bubbles from forming, and makes them take the most natural appearance. [A.B.C.]

8.—Bergin treated 17 cases of **influenza** in what he calls full "open air" wards, that is, those in which all the windows and ventilators were wide open day and night. Although there was always fire in the wards during the winter, the temperature in them was seldom more than 2 or 3 degrees higher than the temperature outside. The average temperature of the wards was 42 degrees. From his tables it will be deducted that those treated in the "open air wards" had; (1) Lessening range of fever; (2) Much shorter duration of fever; (3) Freedom from complications. [A.B.C.]

4.—Pavy says there is no liability to diabetic coma from the "alimentary" form of **diabetes**; this only comes with the "composite" form of this disease. The ordinary "alimentary" form is comparatively easily controlled in most cases by dieting—by withholding excess of carbohydrates from the patient's food. The special danger lies in the proneness of the "alimentary" form to pass into the "composite" form. This form is characterized by disintegration of the tissues of the body; wasting follows, coma may supervene, and death finally results. In the treatment of the alimentary form the author lays stress on the fact that after the patient has been for a time on restricted diet and has a sugar-free urine and then begins to lose weight and have the same depressed feeling that characterized the onset of the disease, the indications are that his system has acquired a tolerance for more carbohydrate material than the restricted diet allows; so this should be increased. The patient then usually gains in weight. "Alimentary" diabetes developing in young persons is more difficult to control, and more liable to pass into the "composite" form than when it develops later in life. The *composite* form is indicated by the presence of oxybutyric acid by the cupric-oxid reduction test, and diacetic acid by the ferric-chlorid test. The latter test is especially valuable. Diabetic coma is the result of a true autotoxicosis, and not due to acetone, as was formerly supposed, but probably to the presence of B-amido butyric acid, as suggested by Sternberg. [A.B.C.]

5.—Gilford says 4 **primary growth diseases**—hypoplasia, hyperplasia, degenerative hypoplasia, and degenerative hyperplasia—may attack the skeleton. They form two divisions, of which the one—hypoplasia and hyperplasia—is distinguished by defect or excess of normal growth; while the other, in which are comprised the two degenerative diseases, shows all those broad clinical and anatomical features which are characteristic of the degenerative diseases of growth, whatever the tissue may be that they affect. And as degenerative hypoplasia of the skeleton is seen to run into degenerative hyperplasia by imperceptible gradations, each being distinguished from the other by characters imprinted by age alone, so degenerative hyperplasia is subdivided into two diseases, according to tissue. If it affects the hard part of the skeleton especially, it is called osteitis deformans; if the soft substance, it is called osteomalacia. In the main these two diseases are distinct, yet they often overlap each other. Their differences are mainly those due to differences in tissue, function, sex, and age. All other tissues of the body are liable to the same four kinds of disorders, and all are affected in the same way, varying only to the extent to which one tissue differs from another. [A.B.C.]

6.—Hall describes a case of **syphilitic fibrospontoid osteitis** occurring in a boy, who was 14 years of age at the time seen. The boy's mother was in good health, the father was delicate. The patient, who had snuffles as a baby and was always delicate, was the eldest of 5 children, 2 of whom died in infancy and 2 were stillborn. The boy did not walk until 5 years old, and anterior bending of the legs was noticed 18 months afterwards. He complained of aching pains in the legs at night. When examined the teeth were irregular, the palate arched, and the lower jaw, right humerus, the clavicles, and both tibia were much enlarged

and somewhat nodular, showing there had been an osteitis. There was also thickening of the skull, especially of the right temporal bone. The most notable feature was the enlargement, elongation, and anterior curve in the middle two-fourths of the tibia. A point in differential diagnosis between this case and rickets is that in the latter the curve in the tibia occurs in the lower segment of the bone. Hall is of opinion that one reason so few cases of this disease are reported is that it is often confounded with rickets. Parrot describes 2 osteophytic forms of bone affection in congenital syphilis, viz., the osteoid form, and the fibrospongoid or rachitic form. The osteoid form may develop in early childhood, and may even be prenatal. The tissues are more brittle than normal bone, and contain large quantities of lime-salts. The spongoid form never develops before the fifth month of life. It begins as a subperiosteal growth of fibroid material over which the periosteum is greatly thickened. The bones most commonly affected are the humerus at its lower end, the ulna, the femur, and the tibia. The two forms are often present in the same case, as they were here. [A. B. C.]

7.—Drake-Brockman recommends the use of **urotrophin** for 3 purposes, viz.: (1) as a urinary antiseptic; (2) as a uric acid solvent; and (3) as a mild nontoxic, and, therefore, harmless diuretic. As a urinary antiseptic it may be used with success in any condition where the bladder or urinary tract is invaded by pathologic microorganisms. As a uric acid solvent it may be used in gout, gravel, and uric acid diathesis. Combined with salicylic acid it appears to increase its efficiency. When used as a diuretic it may cause slight purging, particularly if there be enlarged prostate and irritable bladder. [A. B. C.]

8.—Nash reports estimates made of the urine and urea from 3 patients, each of whom had been **deprived of part of the kidney weight**. The first was a woman of 35 who, 3 years before the experiment, had the right kidney removed, the experiments were continued over a period of 7 weeks. The specimen examined each day being taken from a mixture of the whole for the 24 hours. The average amount excreted in 24 hours was 1520 cc., and the average amount of urea was 1.6%. The second case was a man of 20, who 2 years before the test had about half of the right kidney removed. The experiment covered a period of 52 days. The average daily quantities were 1,167 cc. of urine, and 2.13% of urea. The third case was a woman of 56 who had the left kidney removed, and the experiments were commenced on the day after the operation and continued over a period of 53 days. The average daily quantities were 889 cc. of urine, and 1.57% of urea. The second and third days after the operation the urea was 4.56%, while the urine was 653 cc. and 625 cc. The urine gradually increased in amount until at the end of the 52 days it was running about 1,500 cc. The percentage of urea correspondingly fell. [A. B. C.]

9.—Morison believes that the use of **mercury** in the treatment of **cardiac failure** due to arteriosclerosis is not now being given the attention which it merits, probably from the fact that it was too indiscriminately used formerly. As an evidence of its value he cites the case of a man afflicted with this condition, and in whom **anasarca** was very great, where the diuretic pill composed of 1 grain each of powder of digitalis, powder of squills, blue pill, and extract of hyoscyamus was used. Various other drugs, including strophanthus, digitalis, brandy, diuretin, strychnia, bromids, saline aperients, had all been tried for days without success. Under the use of the above pill the patient began slowly to improve and 12 days after beginning this treatment the urine had increased to 110 ounces. With the relief of the **anasarca** the urine naturally fell, but several times the pill was withheld for some days and each time the urine became scanty and there was evident return toward the former condition. Relief was always afforded by again using the pills. The man, who was 67, regained his ordinary health and a fair degree of comfort, but occasionally had to resort to the pill. [A. B. C.]

10.—Jones treated 7 case of lithemia by having them drink the mineral water from the **Llangammarch Wells**, and he concludes that on the whole the results are most encouraging, and show that in this water we have a powerful agent for the elimination of uric acid. The water is indicated in rheumatism, gout, osteoarthritis, and in all forms

of uric-acid diathesis. A valuable adjunct to the treatment is the exercise in the mountain air of the vicinity. [A. B. C.]

11.—Turner reports a case of a probably true **hermaphrodite**. The individual was 14 years old, supposed to be a girl, and had been "ruptured" since birth, wearing a truss until 12 years of age, after that no support was worn. She had never menstruated. She was admitted to the hospital, and an oval irreducible swelling in the left inguinal region was supposed to be a prolapsed ovary. This was removed and found to be a testis lying over the external abdominal ring. Microscopic examination showed it to be histologically a well-formed testis. The external organs of generation were like those of the normal female. The vagina was a mere culdesac about 1½ inches in depth. There was no uterus and no body resembling a prostate. [A. B. C.]

12.—A woman of 59 had been subject for 2½ years to sudden attacks of severe pain in the region of the gallbladder extending down to the umbilicus and lasting several hours; when very severe it extended through to the back. The attacks were accompanied by vomiting and shivering, and occurred about once a fortnight. Three months previously she became jaundiced after an attack of colic and the discoloration had continued. The urine contained bile. The feces were clay-colored and she suffered from constipation. The gallbladder could not be felt on abdominal palpation. On opening the abdomen, the stone was felt to the right side of the head of the pancreas, but as very extensive adhesions prevented the common duct from being exposed from the outer side the anterior wall of the second part of the duodenum was incised, the opening of the common bile-duct into the duodenum was incised upwards, and a **large gall-stone was removed**. The incision into the opening of the common duct was not sutured. The incision through the anterior wall of the duodenum was closed as follows: A continuous catgut suture passing through the coats of the bowel was first inserted, then the line of suture was covered in by a continuous suture of fine silk passing through the peritoneal coat alone; one or two Lembert's sutures were put in at the ends of the incision. The abdominal wound was then closed with three tiers of sutures. No drainage was employed. After the operation the patient was troubled with bronchitis, but eventually completely recovered. [M. B. T.]

1.—Elizabeth Mercelis reports a case of **primary carcinoma of the fallopian tubes**. The determining points for primary development in the tube are: 1. The absence of malignant growth in the uterus, as shown by microscopic examination of curettings at the time of operation. 2. The presence of an old salpingitis, together with the freedom of the inner end of the tube from malignant change. 3. An enlarged tube, the lumen of which is filled with carcinomatous masses of even 2.5 cm. diameter. This change found throughout two-thirds of the tube, and with the existence of a pelvic tumor for more than fifteen months. 4. The advanced stage of the growth within the tube and fairly healthy condition of the outer muscle-layers. This, in view of the resistance of the tube to secondary invasion of the ovary, and that such, when occurring, usually involves the peritoneal surface first, the mucosa secondarily. 5. The ovary is not only small, but at the inner end free from the growth. The outer portion is widely invaded, but even here areas of ovarian tissues are found. 6. Microscopic evidence of a more rapid proliferation of the new cells in the ovary than in the tube. All of these force the conclusion that the growth in

the ovary is of more recent development than the advanced coexisting tumor of the tube. [W.K.]

3.—Jenkins reports a case of **atrophy of the ciliary muscle** following the use of improper glasses and the taking of belladonna for some 2 months. He says that glasses which give the eyes too much or too little work and the continued use of a mydriatic may cause an atrophy of this muscle. [G.B.W.]

4.—MacGowan believes thoroughly in the practical use of the **Bottini operation** in cases of prostatic hypertrophy. When first introduced sufficient current was not used in heating the incising blade and the results thus obtained were not promising because of their incompleteness. To properly heat the blade to a temperature which will actively destroy the tissue a current of 4 volts and about 40 amperes is required, and to obtain this amount of current MacGowan employs a storage battery which weighs some 80 pounds. An amperemeter should be always used and a test made beforehand of the amount of current required to heat the knife to a white heat. In most cases a local anesthetic is all that is required; a very good method is to inject into the empty rectum about 40 minutes before the operation a solution of antipyrin gr. xxiv, tr. opii gtt. x, in water f3 iij, and then 10 minutes immediately preceding the cauterization to instill into the deep urethra an ounce of a 2% solution of cocain in a 10% solution of antipyrin. During the operation the bladder should be moderately distended with a boro-salicylic solution. In most cases a single posterior incision is all that will be necessary, but some cases require lateral cauterizations, but the knife should never be made to burn in an anterior direction. [G.B.W.]

5.—Bernhart says the **floaters in the urine** of those having a chronic discharge after gonorrhea are composed of epithelial cells, mucus, and pus. After the acute stage has subsided the follicles and lacunae are involved in a general catarrhal inflammation. As time elapses and this chronicity continues, the mucous membrane and its glands atrophy, and the epithelium undergoes transformation from the cylindrical to the squamous variety. It is the product of this devastation that is washed out by the urine. These washings vary in density and composition, some being mainly epithelial cells, some mucus, others mucus and epithelium with varying quantity of pus, while others are composed almost entirely of pus. The combination of these elements varies so that a classification can be made only according to the one which predominates. As a result of the examination of 50 cases, 6 months to 5 years standing, he comes to the following conclusions: (1) The specific gravity of the urine is a prominent factor in the action of floaters; (2) the elements composing the floaters influence their action; (3) their suspension at different depths in the urine is greatly due to some mechanical interference; (4) upon filtration of the urine all but the very lightest floaters, those composed of flocculent mucus, will sink to the bottom of the beaker; and (5) the action of floaters does not alone depend upon their composition or the specific gravity of the urine. [A.B.C.]

6.—Gant report 2 cases of **rectal disease**. The first was one of rectal ulceration causing a chronic diarrhea which resisted all treatment until the cause of the disease was located. The ulcers were thoroughly cured and touched with silver nitrate, and in six weeks they were healed and the patient was discharged cured. The second case was one of stricture of the rectum caused by pressure from a large bladder-stone. The stone, which after a good deal of trouble was removed through the perineal route, weighed 4½ ounces. The stricture of the rectum was broken up and the neighboring ulcers cured, and in four weeks the patient left for home a cured man except for a perineal fistula which did not close until almost a year later. [G.B.W.]

Medical Record.

July 14, 1900. [Vol. 58, No. 2.]

1. Some Clinical Observations on Lupus Erythematosus; the Pathology of Lupus Erythematosus. J. A. FORDYCE.
2. Endocardial Murmurs of Organic Origin, Localized in the Pulmonary Area of the Heart. JOHN WINTERS BRANNAN.
3. Convulsions. CLARENCE KING.

1.—Several cases are reported which in their clinical features show some interesting points. In one case a symmetrical **lupus erythematosus**, which began two months after pregnancy, came on and disappeared in the latter part of pregnancy. The symmetrical arrangement of the eruption and its association with pregnancy pointed toward a possible toxemic origin of the disease. In another case of long standing there were marked general symptoms,—chills, fever, headache, and pain,—also indicating a probable toxemia. In the third case lupus erythematosus was apparently secondary to tuberculosis of the skin. This case was a support for the opinion that had previously been expressed that lupus erythematosus was due to the toxin of the tubercle-bacilli. In discussing the pathology of the disease Fordyce insists that it is important to fix the tissues properly in order to demonstrate the presence of mononuclear leukocytes in the capillaries. He uses formalin, absolute alcohol, and mercuric chlorid as fixing agents. The changes were divided into three groups—round-cell infiltration, peculiar degeneration of the connective tissue, and a secondary atrophy. There was no evidence in the sections of the tuberculous changes. The alterations are described in detail, the two early changes which are always present being a mantling infiltration of the capillaries and dilation of their caliber. There was no evidence of inflammation from a local septic cause. The change was not capillary thrombosis, because there was no evidence of clotting; fibrin was entirely absent. In summing up their results they conclude that the disease is one in which the blood-supply is interfered with, and the normal capillary pressure is raised. The capillary obstruction is probably primary, the infiltration secondary, and the connective tissue change thus results; or probably the connective-tissue change is primary. They do not think that the connective-tissue degeneration contains elastin, as Unna has stated. The collagenous substance does take a dark brown stain with orcein, but it does not react to the other stains for elastic tissue. [D.L.E.]

2.—Brannan describes 2 cases in which there were **systolic murmurs** in the pulmonary region of the heart, with enlargement of that organ, chiefly of the right side and upward, and with a systolic thrill in the pulmonary region. These were both apparently instances of acquired disease of the heart. There was no cyanosis and there had been no evidence of circulatory disturbances until the patients had attacks of rheumatism, the cardiac signs developing after this time; hence it was thought that they were not congenital. There was no evidence that the murmurs were cardiopulmonary, and Brannan decides that they were probably mitral murmurs transmitted to the point where they were heard through the medium of the enlarged appendix of the left auricle. [D.L.E.]

3.—King describes cases illustrating various forms of **convulsions**. One of them was of some interest in that it occurred after taking a dram of oil of tansy for the purpose of producing abortion. [D.L.E.]

Medical News.

July 14, 1900. [Vol. lxxvii, No. 2.]

1. Tendon Transplantation in the Treatment of Deformities of the Hand. WISNER R. TOWNSEND.
2. Some Remarks on the Artificial Feeding of Infants and the Regulation of the Milk-Supply in the Country. B. J. FINLEY BELL.
3. Subphrenic Abscesses Following Appendicitis; 2 Cases. J. F. BALDWIN.
4. Petroleum in the Treatment of Phthisis. WILLIAM DUFFIELD ROBINSON.

1.—Townsend reports 17 cases of **tendon transplantation** of the forearm, and the results obtained are so favorable that many cases of wrist-drop following cerebrospinal meningitis can be assured of fairly useful arms where formerly amputation would have been deemed advisable. All cases on which this operation is to be done should be most carefully studied beforehand to determine which muscles are active and can be relied upon to furnish activity to the paralyzed tendons. Muscles can be made to do work for which they were never intended, i.e., an extensor muscle may be transplanted to a paralyzed flexor tendon, and the patient will then be able to voluntarily bend the finger or fingers

supplied by the transplanted tendon. The method recommended of uniting the two tendons is to split the tendon to which the attachment is to be made, and the end of the severed tendon, after it has been scored across to make it rough is drawn through the split and held there by 2 quilted sutures. Whether it is better to carry the transplanted tendon outside around the bones of the forearm or to pass them through the interosseous space is not yet decided, but good results have been obtained after practising the interosseous method. [G B.W.]

2.—Bell gives a long and interesting discussion of the **modification of milk for infant feeding**. According to him, none of the artificial foods prepared by the various commercial companies are of any particular value. With nearly all of them the child develops signs of rachitis. Perhaps the most pernicious is condensed milk, which ordinarily contains too little fat, an excessive amount of proteids, and too little sugar. During lactation, human milk usually shows a diminished proportion of proteids, but in artificial feeding it has been the custom to increase the proportion of proteids gradually from .75 to 2.25%. Bell has found that in general a considerable reduction below this of the proteids is desirable. In 2 cases he found that 1.25% of proteids caused the production of casein curds in the stools, and that 1% was about the maximum quantity. Sometimes whey is much better borne than even modified milk. He calls attention to the differences between the constituents of human and cow's milk and then discusses the various methods used to modify milk. Finally, he discusses the subject of the production of as pure a quality as possible of cow's milk. In order to do this, it is necessary to reform the cow, the dairyman, and the distributor. The cow should be kept healthy, should be tested for tuberculosis, and her diet should be made suitable, including at least ten pounds of grain per day. The dairyman should be intelligent, should understand the necessities of the situation, and be able to practise continually rigid antiseptic precautions. The distributor should see to it that the milk is kept cold from the time it leaves the cow until it reaches the consumer. In addition to tuberculosis, any infectious disease of the nipples should be watched for and the cow possessing it at once excluded from the herd until well. If the milk is of good quality and maintains a reasonable number of bacteria, not more than 10,000 per cc., it is not necessary to pasteurize or sterilize it. Often under the most careful precautions children do poorly upon laboratory milk. Probably the most favorable conditions are home modifications in the country, where the milk can be obtained in an almost pure state, providing the dairyman possesses sufficient technical knowledge. [J.S.]

3.—Baldwin reports 2 cases of **subphrenic abscess following appendicitis**. The first was a woman, 49 years of age, who for some time had suffered from symptoms of chronic appendicitis, so that it was finally decided to remove the appendix. This organ was found to be greatly elongated and catarrhal, and its removal was followed by a rapid convalescence on the part of the patient. But in a little over 2 weeks there was a return of the pain and a rise of the temperature, and some enlargement of the liver was noticed. A few days later there developed every evidence of an abscess pointing at about the top of the twelfth rib, and an incision in this region evacuated an enormous amount of pus and opened a ragged abscess-cavity between the liver and diaphragm. Drainage tubes were inserted and the cavity healed very rapidly. The second case was that of a girl suffering from a very acute attack of appendicitis, and at the operation perforation of the appendix was found. The patient convalesced rapidly from the acute attack after the appendix had been removed, but shortly afterward fever, with sweats and rapid pulse, came on again, accompanied with enlargement of the liver. Operation revealed an abscess about the size of an orange, situated between the upper surface of the liver and the diaphragm, which, however, healed promptly after good drainage had been established. [G B.W.]

4.—Robinson believes that **petroleum oil** is of considerable value in the **treatment of phthisis**. He gives large quantities, and his experiments have shown that practically all ingested may be recovered in the feces. He believes that its action is purely mechanical; that is to say, it dissolves and carries off the toxins formed in the intestines. It acts as a germicide by excluding moisture and light from the bacteria, and is an ideal solvent and diluent for many reme-

dies, such as creasote. Ordinarily its administration results in considerable gain in weight. There is no evidence that it has any true medicinal virtue. [J.S.]

Boston Medical and Surgical Journal.

July 12, 1900. [Vol. cxliii, No. 2.]

1. A Review of Recent Studies on the Nature and Origin of Cancer. J. COLLINS WARREN.
2. A Case of Mural Endocarditis. HAROLD WILLIAMS.
3. Cysts in the Abdominal Wall Structurally Identical with Ovarian Cysts. JOHN HOMANS.
4. A Case of Cesarean Section. THOMAS KITTREDGE.

1.—Warren has summarized some of the more important articles upon the subject of **carcinoma**. Regarding its distribution, he finds that it extends from Norway to the southern part of Europe, it is probably as frequent in Holland as anywhere else, and in the most southern parts as in the most northern parts of it is rather less common. It seems to be almost unknown in Northern Asia, and to be very rare in Southern Asia. It is also exceedingly rare in Africa, appearing only in Algiers and in Madeira. In the United States, it is probably more common in San Francisco than anywhere in the East, and it is fairly common in Australia. He believes from this that cancer is apparently a disease of the temperate zone and it seems to be somewhat more common in the western part of both hemispheres. Geologically, it seems to be less common in the oldest rock-formations. He then discusses the question of cancer-houses and the distribution of cancer in certain areas in cities, and also the fact that those who live much in the woods are perhaps more subject to the disease. He admits that cancer is becoming more frequent than formerly, but attempts no explanation. All these facts point to the existence of a local cause that acts endemically, but at present we are very far from any knowledge as to what this cause may be. As the disease appears to be as common in the carnivora as in the herbivora it is hardly likely that it is the food. He reports a number of cases of apparent contagion, and then discusses the experimental literature on the subject. He does not think that inoculations have led to much result, but admits that inoculations from animals to other animals of the same species are sometimes successful. None of the parasites hitherto described appear to have any etiologic relation to the disease, excepting the blastomycetes, and it is difficult to understand how these act. In conclusion he outlines the future work for the discovery of the parasite. [J.S.]

2.—Williams reports a case of a woman of 54 who had an attack of **dyspnea** with pain in the region of the heart. She was immediately put to bed and remained there until her death, nearly 3 months later. From time to time she had attacks of dyspnea with loss of pulse, but throughout the course of the disease there were no murmurs to be heard and no thrills to be felt in the heart. The heart sounds were weak. A diagnosis of fatty heart with sclerosis of the coronary arteries were made. At the autopsy, examination of the heart showed a superficial whitish layer in the left ventricle from 1 to 3 millimeters in thickness that could readily be moved about on the underlying muscle. This proved, microscopically, to be a proliferative **myoendocarditis** in which the inner layer of the heart-muscle had been replaced by dense fibrous tissue. There was segmentation of the heart-muscle. The interesting features of the case are the localization of the process on a portion of the wall of the left ventricle and the absence of cardiac murmurs. [J.S.]

3.—Homans, after operating on a patient for an enormous **ovarian cyst**, weighing with its contents 102 pounds, found, 2 months later, various cysts entirely independent of one another and of the abdominal contents, scattered about in the abdominal walls. They were removed, and one of them was examined at the pathological department of Harvard College, and the following report rendered: Of abdominal walls, microscope shows a dense fibrous tissue and fat and muscle, with a small area of more cellular fibrous tissue in which there appear epithelial structures of the type of ovarian cystadenomas, a single layer of cylindrical cells forming irregular gland acini: Malignant cystadenomata of ovary. The cysts were removed, but the patient died somewhat suddenly, apparently of a thrombus. [W.K.]

4.—Kittredge reports a case of **cesarean section** in a

patient having pelvis contracted in all diameters, the antero-posterior being less than 3 inches, with a very oblique superior strait. An unusual incident occurred on the third day after operation, when, during the temporary absence of the nurse from the room, the child began to cry, and the patient got out of her bed, walked across the room, took the baby from its crib, and carried it back to her own bed. Notwithstanding, the patient made an uninterrupted recovery, was able to nurse her infant and left the hospital in 3 weeks. [W.K.]

7. The Plague in San Francisco. DOUGLASS W. MONTGOMERY.

1.—Will be treated editorially.

2.—Chapin gives some suggestions with regard to modifying milk for feeding infants. He also speaks of milk supplies and the methods of handling the milk from the time of milking till used. The article does not lend itself readily to abstract, and those interested should refer directly to it. [M.B.T.]

3.—Following the suggestions of A. H. Smith, Bridges has used guaiacol and the salicylates in the treatment of 8 cases of pneumonia. This treatment is based on antibactericidal grounds and from his experience Bridges states that he would rely upon these drugs as specifics in pneumonia, giving preference to the former in cases past the stage of congestion, in the enfeebled, or when there were heart-lesions. The addition of strychnia to the salicylate treatment obviates in part the depressant effect upon the heart, as does alcohol. As to the symptomatic treatment it is in no wise interfered with by this method. Bridges has found hot poultices more agreeable than cold; he advises venesection when there is an overloaded right heart with threatening symptoms; digitalis is reserved for an irregular and flagging heart; codein in small doses for the relief of pain and delirium; strychnia in increasing doses and alcohol for enfeebled heart-action; calomel and salines for constipation or sluggish portal circulation; oxygen gas is commenced at the first sign of cyanosis and in quantity sufficient to relieve; and, most important of all, the absolute recumbent posture until resolution is established. [M.B.T.]

4.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, p. 1271.

5.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, p. 1003.

6.—Bullard believes that apoplexy unaccompanied by motor symptoms is often overlooked by the general practitioner, or its manifestations are not understood, while even the specialist is at times in doubt in the more obscure cases. It is not, however, a very rare occurrence. Three cases of this kind are reported. These cases differ pathologically from cases of ordinary apoplexy with motor symptoms, probably only in the seat of lesion. Clinically we find usually a marked degree of mental involvement, on the whole more pronounced than in the cases with motor symptoms. The diagnosis, while evident enough if the initial attack is seen or carefully reported, is often difficult when the patient is seen later. The mental weakness, the dementia, and the loss of memory prevent the acquirement of an accurate history. The presence of partial aphasia might suggest a condition of this character, but does not necessarily prove it. In the differential diagnosis the most important evidence is the sudden onset of the symptoms. If motor symptoms, even though very slight, have been present, this favors the diagnosis. When we see a patient some time after the appearance of the mental affection and no history can be obtained, the diagnosis depends on the character of the mental impairment and the absence of symptoms pointing to paralytic dementia or to intracranial tumor. The second element in the differential diagnosis of the results of "primary" apoplexy from

paralytic dementia or other cerebral affections is the presence or absence of the symptoms characteristic of these affections, but not usual in the simple apoplexies. The condition of the pupils, tremor, or peculiar mental condition common in paralytic dementia, the severe headaches, optic neuritis or optic atrophy of brain-tumors, together with other symptoms common to these affections considered separately or as a symptom-complex, will enable one to determine the pathologic condition. 7. Radical Treatment for Curvature of the Penis. EUGENE FULLER.
8. Report of a Case of Exstrophy of the Bladder, with Remarks upon the Operative Treatment of that Condition. BRANSFORD LEWIS.

1.—Dunham mentions the following influences which may cause leukocytosis in patients who are undergoing surgical treatment: A hearty meal, the first years of life, hemorrhages, ether-anesthesia, and the absorption of iodoform; carcinoma apparently has a tendency to increase the leukocyte count and the same seems true of sarcoma. The blood-count is of greatest value in diagnosis of acute inflammatory conditions, however; if other influence can be excluded it is a safe guide, but it is important to make two or more counts at intervals. In the early stage of appendicitis, the stationary or downward tendency may point to the advisability of delaying intervention. Suppuration without leukocytosis may be present in patients who are greatly prostrated. Some details with regard to the technic of blood-count with the Thoma-Zeiss apparatus are given. Emphasis is laid on the fact that while the blood-count may be made by some one else its import should be interpreted by the surgeon in charge. [M.B.T.]

2.—McLaren reports a case of congenital dislocation of the patella. A girl of 19 had never walked securely, was never able to run, and was troubled by frequent falling. On examination the patellar fossa of the trochlear surface of the femur could be felt partly filled up and the patella was placed externally and high up. An x-ray photograph was also taken. The existing knockknee was corrected by an osteotomy and about 3 months later a U shaped incision was made over the knee. The outer extension of the quadriceps tendon was exposed without opening the cavity of the joint, allowing the patella to be brought easily to the middle line, 2 holes were then bored through its inner side and stout catgut sutures were passed through and sutured to the internal lateral ligament. Union by first intention resulted, but the sutures did not hold sufficiently long, and the bone gradually slipped back to its old position. About 8 weeks later the operation was again performed, stout silk being used instead of catgut. Uneventful recovery followed and the bone remained in its normal position. For 4 years the patella has retained its position, the patient walks with confidence without fear of falling, and is able to run. McLaren believes that the operation of transplanting the ligamentum patellae should be reserved for cases in which there is a high degree of outward rotation of the leg. He mentions 30 cases of congenital dislocation of the patella which have been collected by Appeal and he has added several to the number. [M.B.T.]

3.—A man of 39 fell striking on his left shoulder; pain developed which was treated by antirheumatics and fixation with a plaster-of-paris bandage without result. An abscess developed which was opened and several times cured; finally a resection of the head of the humerus was undertaken at the surgical neck. The bone was extensively diseased, as was the medullary cavity. The entire medullary

canal was cureted, an emulsion of iodoform in glycerin was injected and drainage was inserted. Temporary improvement followed, but 3 months later other pus cavities required evacuation and soon after shoulder-joint amputation was performed. Prompt recovery followed. The entire humerus was found to have been affected by osteomyelitis. Some 10 weeks later there was an extensive recurrence of infection in the glenoid cavity; the diseased portion of bone was removed, but later on it was found necessary to perform **interscapulothoracic amputation**, removing the remaining portions of the clavicle and scapula. The entire raw surface of the flaps was swabbed with 2½% solution of formaldehyd in equal parts of alcohol and water, and gauze wrung out in the same solution was packed in. The patient reacted well and was convalescent in a fortnight. [M.B.T.]

4.—Murray gives a short review of the literature in regard to the treatment of **fractures** by administering **thyroid extract**. He reports the case of a man of 28 who was struck by a locomotive, sustaining 2 simple fractures of the left femur, one at the juncture of the upper and middle third and the other at the lower third of the bone. At the end of 2 months there was nonunion and overlapping of the fragments. Freshening the ends and fixation with plaster of paris was given a thorough trial, and wiring was carried out on 2 occasions without any beneficial result. Some time after the second operation of wiring thyroid extract was administered in doses of 2 grains, gradually increased to 4 grains, 3 times a day. The result was not entirely satisfactory, but there has been gradual improvement since beginning thyroid medication, and Murray is inclined to give it credit, as there were no signs of progress until its administration was begun. [M.B.T.]

5.—A woman of 39 had noticed a tumor in her abdomen which had existed for 2 years. It increased in size until it extended from the diaphragm of the left side into the pelvic cavity where it was easily felt by vaginal examination. Examinations for the malarial parasite were made with negative results. The patient was kept in bed 8 weeks and general treatment administered without any improvement. **Splenectomy** was then performed and since the operation the patient has greatly improved and the condition of her blood is now normal. The spleen weighed 4½ pounds and on microscopic examination chronic passive congestion with hypertrophy of the pulp and follicles was found. [M.B.T.]

6.—A woman of 54 had an **umbilical hernia** which extended to the knees. On account of the **enormous size** of the hernia, operation was not thought advisable, but when ulceration of the wall of the sac resulted a few months later, it was considered imperative. On opening the sac it was found to contain part of the ascending colon and descending colon with the transverse colon and all the small intestines, except a small part of the duodenum and ileum; they were firmly matted together with adhesions. The abdominal ring measured about 14 inches in circumference. On account of the large size of the opening, part of the sac was used for covering to close the ring; after the operation there was severe persistent vomiting for 4 days, which is believed to have resulted from the pressure of the viscera against the stomach; recovery resulted, however, and the patient returned to her home in less than 4 weeks. [M.B.T.]

7.—A boy of 12 years contracted gonorrhea from his nurse, which ran a severe course and two years later resulted in stricture of the anterior urethra. Internal urethrotomy was performed by a prominent specialist. Considerable inflammation followed the operation and a permanent **curvature of the penis** resulted. Without knowledge of any attempt at radical cure of such deformity Fuller undertook the following operation: The perineum was laid open just in front of the rectum to the scrotum; the urethra was cut obliquely in the bulbous region; the penile portion was dissected free and the organ was pulled up and bent back over the pubes and a perineal vesical drainage-tube was inserted; the penis was left bent back and secured by transverse strips of plaster. The wound healed well and the result is considered successful two years after the operation. [M.B.T.]

8.—The case of a man of 27 is reported who suffered from **exstrophy of the bladder** and **epispadias**; by the aid of a rubber receptacle the patient is able to catch the urine as it emerges from the ureters. He does not suffer actual pain and is able to undertake ordinary labor. [M.B.T.]

Wiener klinische Wochenschrift.

1. A Study of the Normal Relations of the Thoracic Aorta with the X-rays. G. HOI ZENECHT.
2. A Case of Congenital Hypertrophy of the Pylorus. FRANZ HANSY.
3. Biology of Malarial Parasites. XAVER LEWKOWICZ.

1.—An article dealing with the results of radiography of the aorta. The most valuable pictures are obtained by examination in the sagittal direction and in the direction from left posterior to right anterior. [D.R.]

2.—A boy of 11 came under observation with abdominal distention and a tumor in the region to the left and below the umbilicus. As he had no relatives his history was obtained with difficulty. The boy had a good appetite, but had been vomiting indigested food with increasing frequency after meals. As the tumor could be plainly felt, operation was thought to be indicated. On opening the abdomen a circular uniform **hypertrophy of the pylorus** was found; the tumor was about 7 cm. in length, 2½ cm. in thickness. **Gastroenterostomy** with Murphy's button was performed. There was considerable vomiting the first days after the operation. But the latter course was favorable and since the operation the boy does not vomit, and he has a good appetite and digests all sorts of food. [M.B.T.]

3.—The author believes that there is a malarial fever that has a 22-day interval (**febris vigesimotertiana**), which is connected with the time required for the development of the malarial crescents. He is of the opinion that there is only one malarial parasite with a polymorphic character. Regarding the source of infection, he believes that the infection is direct, *i. e.*, the same mosquito that has stung the malarial patient transmits the disease to a healthy individual. The material by which the disease is carried from one year to another is the malarial crescents of chronic malaria, particularly as they can survive through the winter. It is the blood from cases having these crescents that gives rise to tertian fever in others, possibly by direct conveyance through the mosquito, or after the crescents have passed through certain metamorphoses in the insect's body. It is probable that the malarial parasites can live in the winter only in the human body. If this is so, then the link between the malarial epidemics of one year and those of the succeeding year is constituted by the chronic cases that pass through the winter. This link can be broken by means of quinin. The object can be accomplished by examining the blood of suspected chronic cases, or by subjecting the entire population in a malarial district to quinin treatment for one or two weeks during the winter. [D.R.]

1. The So-called Pericarditic Pseudocirrhosis of the Liver. VICTOR EISENMENGER.
2. Hematopolypus and Hematometra in Consequence of Congenital Atresia of the Hymen. E. TOFF.
3. The Diagnosis of Diverticulum of the Esophagus. VICTOR BLUM.

1.—In 1896 Pick described as a new nosologic entity a condition characterized by symptoms resembling cirrhosis of the liver, but presenting as a pathologic basis chronic adhesive pericarditis. Eisenmenger disputes the existence of this so-called **pericarditic pseudocirrhosis**. Pick had maintained that the circulatory disturbances in the liver produced an overgrowth of connective tissue which by interfering with the portal circulation led to ascites. This the author contends is not proved. Passive congestion of the liver does not lead to genuine cirrhotic processes; the only hyperplasia of connective tissue that is found affects the walls of the central vein and is incapable of producing ascites. He admits, however, that in cases of adhesive pericarditis high degrees of ascites without edema of the legs can occur, and that if the pericarditis be latent the symptoms are suggestive of cirrhosis of the liver. But the cause is not an overgrowth of connective tissue the effect of stasis, as maintained by Pick, but it may be a variety of conditions, among others, torsion, compression, or angulation of the inferior vena cava by reason of an existing pleural exudate, or through pericardio-mediastinal adhesions; secondly, through localized periton-

itis at the transverse fissure of the liver. The fact that the condition occurs more frequently in young individuals is also important, inasmuch as in youth the vessels of the systemic circulation have a better tone and are not so liable to transudation processes as they are in advanced age, while the vessels of the peritoneum are not so much under the influence of the age factor. Since, therefore, there is no single anatomic basis for the condition described by Pick, and since the term pericarditic pseudocirrhosis implies a diagnostic error as regards the liver-condition, the term should be abandoned. [It seems to us that the author's points are not altogether well taken. While it may, of course, be improper to consider the condition described by Pick as a distinct disease entity, it is important to know that adherent pericardium frequently gives rise to ascites. The existence of ascites in a case without anything in the history pointing to cirrhosis of the liver, may suggest the presence of an adherent pericarditis. The latter is generally very difficult of diagnosis, and when not before the mind is apt to be overlooked. If, however, in every case of ascites of obscure origin the heart is carefully examined, it may be that we shall make a diagnosis of pericardial adhesions more frequently. D.R.]

3.—A man of 66 had been troubled by his food not passing into the stomach; it seemed to lodge in the region of the larynx and by pressing with his thumb in the region of the right side of the larynx he was able to force the food out with a readily heard gurgle and the food, without being changed, was returned to the mouth. Sometimes food which had been ingested 24 hours or more could be forced out in this way. On examination with a large esophageal sound an obstruction was encountered which could not be overcome, 23 cm. from the teeth. The sound could not be carried to the middle line; sometimes it was even possible to pass one sound into the stomach while another met the obstruction at the same region. The esophagoscopic tube was inserted, but only normal mucous membrane was found. A **diverticulum of the esophagus** was suspected and 50 cm. of a 5% bismuth mixture was given; at the same time a closed rubber tube was inserted in the stomach and filled with mercury. An x-ray photograph was then taken and it showed an oval-shaped shadow in the region described, to the left of the median line. Blum recommends this as a very satisfactory method of making the diagnosis of diverticulum of the esophagus. [M.B.T.]

March 22, 1900. [13. Jahrg., No. 12.]

1. Cirrhosis of the Liver. RICHARD KRATZ.
2. Some Results of the Determination of Blood-Pressure in the Insane. ALEXANDER PILCZ.

1.—Kratz defines **cirrhosis of the liver** as "a focal, localized, recurring, chronic process, with intercalated regeneration of the parenchyma." The process begins as small foci of degeneration at the periphery of the acini, and is followed, aside from a disintegration of the degenerated portions, by a regeneration. The latter occurs primarily at the periphery of the acini in the zones of the tangential distribution of the portal vessels; in part also as an interpolation of young elements between the cell columns. Such an alternating degeneration and regeneration of functional parenchyma leads gradually to a transformation of the normal acini and to a change in their form, the process affecting particularly the capillary distribution, and in that way the nutrition of the parenchyma. Later, the more deeply-seated portions of the parenchyma are also involved. Here the disintegration brings about a destruction of the intraacinous portions and to a more active regeneration of the tangential parenchyma. Gradually the process leads in different places to a complete destruction of the acini and of the newly-formed parenchyma. Eventually the reproductive power of the liver-cells becomes exhausted and degeneration predominates over regeneration, and goes on to progressive atrophy, which in turn leads to death directly, from loss of hepatic function, or the individual dies from some intercurrent disease. [The principal point of this somewhat obscure theory rests upon the enormous reproductive capacity of the liver-cells, which manifests itself very early in the disease. D.R.]

2.—Pilcz has examined the **blood-pressure** with Gärtner's tonometer in various forms of **insanity**. The normal pressure is from 105 to 130 mm. mercury. In **general**

paralysis the blood-pressure in the beginning is about normal; later it falls progressively, reaching in the terminal states a very low figure (50 to 80 mm.). When a remission occurs the fall in blood-pressure seems to become arrested. In **hebephrenia** the blood-examinations were unsatisfactory, different cases giving different results. In **melancholia** the blood-pressure was always high. In **circular insanity** the variations in pressure were parallel with the changes in the psychic state; in the melancholic phases the pressure was very high, in the maniacal low. In **epilepsy** the author was able to take the blood-pressure during the attack in only two cases. In one he found in the transition from the tonic to the clonic stage the pressure to be 220 mm., and in the other during the clonic stage 150 mm. In the postparoxysmal stupor the blood-pressure sank in the first to 80, and in the second to 70 mm. Fifteen minutes later it was 135 in the first, and five minutes after, 125 in the other. [D.R.]

March 29, 1900. [13. Jahrg., No. 13.]

1. A Case of Intraabdominal Torsion of the Mesentery. J. HOCHENEGG.
2. Löwit's Hämamöben in the Blood of Leukemic Patients. WILHELM TÜRK.
5. The Second Pulmonary Sound. ADOLF HECHT.

1.—A man of 41 years was taken ill with abdominal distention, nausea, and vomiting; the next day there was some improvement, but the symptoms recurred and grew worse. The abdomen was opened and immediately a large amount of bloody fluid escaped. A bluish-black tumor of the **mesentery** the size of a man's head, with largely dilated veins, was discovered. This tumor was 3 times twisted on its pedicle. The pedicle was ligated and the mass was excised. An uneventful recovery followed. From an examination of the literature Hochenegg believes this case to be unique. [M.B.T.]

2.—Türk believes that the supposed protozoan of **leukemia** described by Löwit under the name of "Hämamöba leukemia magna" is nothing more than artefacts composed of mastcell granulations. [D.R.]

3.—Hecht discusses the significance of the **second pulmonic sound** of the heart, and gives some results of comparative studies with the Bettelheim Gärtner **stethophonometer**. The character of the second sound is the best index of changes in the pressure in the smaller circulation. In myocarditis the sound is not so loud as in endocarditis. It is less loud in relative insufficiency of the mitral valve than in organic insufficiency. If in the case of the latter there is intense accentuation, there is probably also stenosis of the auriculoventricular orifice. If the right ventricle becomes weak and relative tricuspid insufficiency occurs, the accentuation disappears again. The occurrence of accentuation in aortic disease is indicative of relative mitral insufficiency. In aortic insufficiency judgment is difficult, on account of the disappearance of the second aortic sound, which is the standard of comparison. In nephritis the accentuation of the second pulmonic sound may be readily overlooked when the second aortic is metallic. Congenital pulmonary stenosis with persistence of the ductus Botalli is characterized by a loud second sound. Respiratory diseases, particularly those associated with destruction of the capillaries and chronic emphysema, lead to increased pressure in the pulmonary circulation. The accentuation may, however, be brought about by conditions of resonance, as a neighboring infiltrated portion of the lung, a cavity, a pneumothorax, or a dilated stomach. Certain conditions of gallop rhythm are also associated with increased pressure in the pulmonary circulation. The second pulmonic sound is accentuated at times in perityphlitis, even in the absence of tympany. The cardiac second sounds are loud in nervous affections of the heart, in Graves' disease, in febrile states, in anemia, and in chlorosis. Hecht has measured the relative intensity of the aortic and pulmonic second sounds with the stethophonometer, and finds that this instrument gives very good results. He found the second pulmonic sound a little louder than the second aortic. [D.R.]

April 5, 1900. [13. Jahrg., No. 14.]

1. Alexander Operation for Retrodisplacement of the Uterus. E. EHRENDORFER.

2. Further Investigations with Regard to the Germs of the Female Urethra. FERDINAND SCHENK and LOTHAR AUSTERLITZ.
3. A Reply to Pick's Article on Pseudocirrhosis of the Liver.
4. Hämamöben in the Blood of Leukemics. M. LÖWIT.

1.—Ehrendorfer gives a historical sketch of Alexander's operation and its modifications, and a detailed description of Bassini's modification as to the **closing of the inguinal canal**. The indications for this operation are a simple retrodisplacement, a movable uterus combined with a moderate vaginal prolapse. A fixed retroflexed uterus with great enlargement, apparent disease of the adnexa, and unusual relaxation of abdominal wall, are contraindications to this operation. The value of this procedure is that the uterus is brought in a natural manner into an almost normal position, better than by any other operative method, and the malposition is cured more quickly and permanently than by the pessary treatment. There is no artificial fixation of the uterus, its movement is very little interfered with and its function not at all, all disturbances of pregnancy and delivery being avoided. Ehrendorfer considers Bassini's method of closing the inguinal incision as a very valuable addition to the inguinal procedure, since it at the same time forms a certain preservative against inguinal hernia. He mentions the fact that Polk, Edebohls and Goldspohn, in more than 100 cases of Alexander's operation, did not lose a case, that Johnson out of 250 cases had only one death from sepsis, and the record of 320 cases collected in Boston shows no death. [W.K.]

2.—Schenk and Austerlitz, as the result of their examination of the **urethral germs**, conclude that the vestibule, as well as the urethra, rarely contains pathogenic germs, that in about half of the cases the urethra both in pregnancy and puerperium was free from germs; that in the other half the germs found were mostly saprophytes of different kinds, such as frequently appear in the vestibule; and that in only 2 out of 59 cases of normal female urethras, pathogenic microorganisms were found. [W.K.]

4.—Löwit contends that his **hemameba of leukemia** is not to be confounded with mastcell granulations, as maintained by Turk. [D.R.]

April 12, 1900. [13. Jahrg., No. 15.]

1. The Relation of Korsakoff's Psychosis to Polioencephalitis Acuta Hæmorrhagica Superior. A. ELZHOLZ.
2. Retrograde Incarceration. DOMINIK PUPOVAC.
3. Concerning the Article by Schenk and Austerlitz on the Germs of the Female Urethra. RUDOLPH SAVOR.

1.—A lengthy view of the relationship between **Korsakoff's psychosis and polioencephalitis acuta hæmorrhagica superior**. Korsakoff's psychosis is a peculiar mental disturbance accompanying various forms of polyneuritis, particularly the alcoholic form. It is also designated as cerebropathia psychica toxemica, and bears some analogy to the condition described by Wernicke under the cumbersome title of polioencephalitis acuta hæmorrhagica superior, the anatomic lesion of which is an inflammatory process, with hemorrhages, in the central gray matter surrounding the fourth ventricle, the aqueduct of Sylvius, and the third ventricle. [D.R.]

2.—A case of incarcerated **femoral hernia** is reported occurring in a man of 80. Operation was undertaken partly under local anesthesia. On opening the hernial sac it was found to contain the vermiform **appendix**, which was situated with its extremity toward the abdomen. Unfortunately the man was taken with pneumonia 10 days after the operation and this caused his death. In a second case a man of 46 entered the hospital with an incarcerated right inguinal hernia. Radical operation was undertaken and the sac was found to contain a portion of the mesentery the size of the thumb; the bloodvessels were much distended, and thrombosis had occurred; the free end of the mesentery was directed toward the abdomen. A good recovery followed the operation. [M.B.T.]

April 19, 1900. [13. Jahrg., No. 16.]

1. The Cause of Labor. JOSEF THENEN.
2. The Influence of Alcohol on the Elimination of Reducing Substances in the Urine. ADELBERT GREGOR.

1.—Thenen advances a theory to account for the phenomena causing the beginning of birth. He believes that when the ovum becomes attached to the mucous membrane, a physiologic connection is established between the mother and child which continues so long as the nourishment to the fetus suffices for its needs. The growth of the placenta is comparatively much greater than that of the fetus during the first weeks of pregnancy; but later the placenta grows much less rapidly, and after the thirty-sixth week ceases entirely. The placenta becoming loosened terminates the connection between the two organisms, and the beginning of labor-pains is but the first effort of the uterus to resume its normal function by expelling the fetus or foreign body. [W.K.]

2.—The author's conclusion is that ingestion of alcohol increases the reducing power of urine. [D.R.]

April 26, 1900. [13. Jahrg., No. 17.]

1. Hereditary Syphilis. E. FINGER.
2. Carcinoma of the Intestine in Children. ZUPPINGER.

2.—A girl of 12 had been suffering for 3 months with attacks of colic and severe pain at defecation. Blood frequently appeared in the stools and the abdomen was tympanitic and distended. The condition gradually became worse, stupor developed and death eventually followed. At the necropsy an ulcerating carcinoma of the sigmoid flexure was found; there were metastases in the lymph-glands, liver, omentum and peritoneum. Histologic examination showed a typical cylindrical-celled carcinoma. Zuppinger has found references in literature to a number of cases of **intestinal carcinoma in children**. [M.B.T.]

Münchener medicinische Wochenschrift.

5. Muscle Power under Hot-Air Pressure. v. LIEBIG.
6. Subcutaneous Rupture of the Spleen. TH. COHN.
7. Hystereuryisis. DECKART.

1.—In three infants that at birth were decidedly underweight and that did not thrive on artificial food nor on the milk of a wetnurse, **asses' milk** brought about a rapid increase in weight and an improvement in health. von Ranke believes that this milk is very suitable for the first months of life. It is, however, expensive and not readily obtainable. [D.R.]

2.—Lotheissen says that statistics show that **ethyl chlorid as a general anesthetic** stands, as regards its mortality, next to chloroform; chloroform giving one death to 2,075, ethyl chlorid one death in 2,550. As a practical anesthetic for general narcosis, ethyl chlorid presents the advantages of causing a very rapid insensibility, with little discomfort to the patient; and also that the unpleasant after-effects are almost nothing, the patient awaking very rapidly and vomiting practically never occurs. In one case of death reported by Lotheissen, the patient, a large and muscular man, became suddenly very much cyanosed; respiration gradually ceased, though the pulse was still perceptible at the wrist, and in spite of restoratives death occurred. At the postmortem eccentric hypertrophy of the heart, with fatty degeneration of the heart-muscle, marked arterial sclerosis of the coronary arteries, and slight sclerosis of the aorta, were found. Also, the heart and vein were filled with fluid blood, and there was edema of the lungs. [G.B.W.]

3.—Schüle has made a series of comparative **temperature-measurements** to determine the difference in degree between that found in the **axilla** and that found in the **rectum**. His results show that the axillary temperature is always less than the rectal; the difference sometimes being only .1 of a degree, sometimes going so high as 1.5 degrees. The average of 162 measurements made on 16 nonfebrile

persons was .6 of a degree. In patients with fever the difference is somewhat less, the average being .4. [O.R.W.]

4.—Michaelis believes that **fetal malformations** in the form of abnormally small or irregularly developed skulls are generally due to some mechanical cause, usually resulting from the insufficiency of the amnion, and from the amniotic scars or folds acting as bands which press upon and prevent the normal growth of the fetus, the head and the extremities being the parts most frequently affected. He reports 2 cases, the details of which tend to confirm this view. He accepts as correct the opinion of Winckel, that careful observation and examination tend to show that *all* obstructed fetal growths are due to mechanical causes. [W.K.]

5.—In the pneumatic chamber, under increased atmospheric pressure, the muscles unfold a greater power than under ordinary pressure. [D.R.]

6.—Cohn reports 2 cases of **traumatic rupture of the spleen**. The first was that of a man, 23 years old, who fell, striking the left side of his abdomen on the edge of a chair. As abdominal hemorrhage was undoubtedly present, and the pulse was weak and thready, laparotomy was performed 9 hours after the accident. A large quantity of blood was removed from the abdominal cavity, the hemorrhage having come from a tear in the spleen. The spleen was extirpated and the abdominal wound closed. The patient died the second day after the operation, and the postmortem showed anemia and edema of the lungs. The second case was that of a girl, 17 years old, who fell down a cellar, striking against the left side; rupture of the spleen with internal hemorrhage, was diagnosed, but operation was delayed for 2 days. Then, as the anemia was becoming greater and the pulse weaker, laparotomy was performed. A clot of blood was removed from the abdominal cavity; and the spleen, which was torn in several places, was removed. The abdominal cavity was closed, except for a gauze drain; the patient recovered, and two months after the operation was in apparent perfect health, with no perceptible enlargement of the peripheral lymphatic glands. [G.B.W.]

6. The Treatment of Hereditary Luxation of the Shoulder. CARL GROTHE.
7. A New Improved Respirator. CARL KLEIN.

2.—Schmidt reports a case of **fat necrosis** in a man of 43 years, who had been crushed between the bumpers of 2 railway cars, and who died 53 hours after the accident with symptoms of intestinal obstruction. There was very little hemorrhage, despite the severe injury which the pancreas had sustained. The organ was torn vertically to a depth of from 1 to 2 cm. The author believes that the fat necrosis was due to the escape of pancreatic secretion. [D.R.]

3.—Strubell reports a case of **actinomycosis** of the face which was **cured by hot compresses** (temperature, 63° C. or 145° F.) and **carbolic acid injections**. The first dose of the latter was 12 cc. of a 3% solution. The compresses were continuously applied day and night, being changed every 10 minutes. [D.R.]

4.—The fluoroscope had shown a pulsating tumor in the neighborhood of the heart, and a diagnosis of aortic aneurysm was made. Autopsy showed **adhesion of the aorta and esophagus**, in consequence of a carcinoma starting at the cardia. [D.R.]

5.—A **primary endothelioma of the pleura** was found in a man 43 years of age. There had been a hemorrhagic pleural effusion, in the sediment of which, in addition to large lymphoid cells, rounded and polymorphic mononuclear and multinuclear cells have been found. The author points out the importance of an irregularity in the line of dulness in cases of tumor of the pleura. [D.R.]

6.—Grothe says that in cases of **habitual luxation of the shoulder-joint** the operative narrowing of the cap-

sule is a true radical procedure. The open method of incising the capsule before inserting the sutures is preferable to simply folding the loosened ligament on itself and possesses the advantages of allowing inspection of the joint whereby pathological conditions may be recognized and foreign bodies removed. He reports the case of a man, 27 years of age, who had a shoulder which became dislocated on the slightest provocation. He was operated on by the open method. Some 6 weeks after the operation the patient could move the arm freely in all directions without pain and there was no redislocation of the shoulder within the half-year following. [G.B.W.]

7.—Klein describes an improved and inexpensive respirator. [D.R.]

7. Tuberculosis of the Lymph Glands. H. M. HJUMANS.
8. Results of Testing Hearing with Continuous Tone Series. BEZOLD.

1.—The lateral chain theory of Ehrlich receives strong support from the experiments of von Dungern on the **hemolytic action of blood-serum**. In order that the blood-serum of one animal should dissolve the red blood-corpuscles of another species, the blood must contain an **immunkörper**, which is specific, and a complement, which is nonspecific and is present in normal serum. The complement is the hemolytic agent and takes hold on the corpuscles through the medium of the immunkörper. The immunkörper and the complement are entirely independent of each other. The complement is found in the blood-plasma. Its origin is probably from cells, although probably not in any large quantity from phagocytes. In some forms of immunity the phagocytes may be largely concerned in the formation of the immunkörper; in others, they play only a subordinate role. [D.R.]

2.—The author has found by means of his vital staining method that the **leukocytes** can preserve their life for as long as from 10 days to 4 weeks after withdrawal from the body. By means of the stain he has also been able to study the formation of **bacterial spores**. Spore-formation and germination were found to proceed in the following steps: (1) Separation of the daughter nuclei towards the poles of the elongated bacterial cell; (2) cessation of cell-division; (3) clarification of the protoplasm in the spore half and concentration of the chromophilic substance about the nucleus; (4) the appearance of a membrane about the chromatin body, the gradual loss of staining properties, and the appearance of a fat-like refrangibility; (5) growth of the spore and consequent displacement of the vegetative half; (6) loss of the property of staining, both in the spore and in the protoplasm of the vegetative portion; (7) disintegration of the membrane and of the protoplasm, with the exception of the parts surrounding the spore, and consequent liberation of the spore; (8) swelling of the spore, loss of the refractive power, and visibility of the nucleus or nuclei of the spore; (9) bursting of the spore membrane and exit of the young bacillus. [D.R.]

4.—Fraenkel makes an eloquent plea for the establishment of **special dispensaries for tuberculous cases**. Such institutions would facilitate the early diagnosis of the disease, would strengthen the sanatorium movement by affording better means of selecting the cases, would be useful in spreading the doctrine of prophylaxis, and finally, would afford means of instruction. [D.R.]

5.—Wulff reports an interesting case of **aneurysm of the internal carotid** following an abscess of the tonsil. A girl, 8 years old, was brought to the hospital complaining of sore throat and dysphagia. In the left faucial region the tonsil and wall of the pharynx were markedly protruded which with the enlargement of the submaxillary glands on the left side gave a picture closely resembling postpharyngeal

abscess. But the tumor possessed a marked expansile pulsation, and aspiration brought away nothing except pure blood, so that the diagnosis of aneurysm was made. The history of the case was that during the opening of a tonsillar abscess the carotid artery was wounded causing the loss of a half a liter or more blood, the hemorrhage being controlled after the patient had fainted. The child recovered and the aneurysm gradually developed. Digital compression was tried for a while, but was given up because of the possibility of bursting the sac. The common carotid was then ligated just below its bifurcation. The wound healed by first intention and the pulsation of the aneurysm ceased and did not return. The clot in the sac, however, suppurated and required opening, and later a putrid discharge came from the left ear which, however, finally disappeared. The throat returned to its normal size and when last seen the patient was well in every respect. [G.B.W.]

6.—Muscatello makes some comments upon Heinz's article on the **inflammation of serous surfaces**. (See PHILADELPHIA MEDICAL JOURNAL, June 2, 1900, p. 1232.) He claims that in order for adhesion between two serous surfaces to occur the loss of endothelium is not a necessity. All that is necessary is the formation of a fibrinous exudate. [D.R.]

7.—Contrary to the view enunciated by von Noorden (see PHILADELPHIA MEDICAL JOURNAL, May 19, 1900, p. 1132), the author holds that it is **better not to remove tuberculous glands** unless certain conditions premissorily demand operation. [D.R.]

1.—Jung reports 4 cases of **kraurosis vulvae** observed by him as assistant at Martin's clinic, and also reviews the literature on the subject. The first case was operated upon several times, but the symptoms constantly recurred, and finally the tumor became inoperable. The other 3 cases had been successfully operated upon and there was no recurrence of the trouble at the date of writing. [W.K.]

2.—The man was admitted in a condition in general resembling typhoid fever. He had, however, a boggy swelling about the left temple, and there were small nodules on the left arm which were too large for typhoid spots. The swelling of the temple increased, the number of nodules increased, nasal breathing was obstructed, he grew worse, and finally died in a condition which appeared clinically to be one of septic intoxication. The postmortem examination confirmed the clinical diagnosis of **glanders**. The mucous membrane of the nasal cavities were found covered with ulcers, and there were numerous yellow pustules along the septum and in the muscles. Lesions were also found in the tonsils, larynx, lungs, dura, skin, muscular system, and in the periosteum. Bacteriological examination showed the presence of staphylococci, and a bacillus having the characteristics of the glanders-bacillus. [D.L.E.]

3.—Liesau reports his results from the use of **aspirin**, the drug having been tried in 40 cases. It was given in acute and chronic rheumatism, torticollis, sciatica, exudative pleurisy, pericarditis, in rheumatic pains, and in various other conditions. It was found to be very much better borne than the salicylates, and in only one case was there any evidence of intoxication, which in this instance consisted of ringing in the ears after doses of 1 gram 3 times a day. The same patient when taking salicylates had severe disturbance of the stomach, besides a buzzing in the ears. The drug had a marked diaphoretic effect; its antineuralgic action was pronounced, and it also was effective in reducing fever. In a note to the report he states that 40 further cases have been treated with aspirin with the same satisfactory results, and in only one was there ringing in the ears; in one other case there was tenesmus of the bladder. [D.L.E.]

4.—Lipowski first directs attention to the fact that the diagnosis of **pernicious anemia** is usually based upon the

fact that a severe anemia finally leads to death. At one time the presence of microcytes, macrocytes, and poikilocytes was considered distinctive, but this time is past. At the present time the appearance of macroblasts is considered the most important sign in the blood, but these are not infrequently absent. He describes the case of a woman of 31 who was admitted with very severe anemia which finally caused death, and with hemorrhages from the mucous membranes evidently the result of some poison the nature of which could not be determined. The blood, in spite of the profound anemia, showed no nucleated blood-corpuscles, which Lipowski attributes to the fact that the bone-marrow was not able to react to the stimulus. This supposition was made very probable by observing that 90% of the white cells were lymphocytes, and since the bone-marrow produces the neutrophile corpuscles it appeared evident that the function of the bone-marrow was severely interfered with. He puts the question as to whether this case can be considered one of pernicious anemia. He also directs attention to the fact that evidences of pernicious anemia may be present in the blood-count and in the general appearance of the case without there being present histologic signs of pernicious anemia. In the case which he reports there was constant decrease of the hemoglobin and red-corpuscles until the former reached 10% and the red cells reached 800,000. There were retinal changes, hemorrhages into the skin, irregular temperature-changes, but only shortly before death could he find microcytes; while polychromatic normoblasts and macroblasts were not present at any time. It was certainly a case of pernicious anemia with prolonged absence of the histologic evidences of this disease. In leukemia the blood-condition is usually distinctive, certainly much more so than in any other condition, but he notes a case of carcinoma of the intestine in which there was pronounced reduction of the hemoglobin, with an increase in the white cells as compared with the red of 1 to 18, and with numerous nucleated red cells and some myelocytes. Had a tumor not been found palpable in this case he considers that it would have been impossible to diagnose the case as anything but leukemia. He directs attention to Northagel's case in which actual leukemia was caused by metastasis in the bone-marrow of a lymphosarcoma. He also describes the case of a cook whose blood presented moderate reduction of the hemoglobin and red cells, with an increase of the leukocytes to 1 to 27, the increase affecting exclusively the polymorphonuclear neutrophiles; absolutely no mononuclear or eosinophile cells were found. A carcinoma of the liver was determined to be present. A few large mononuclear cells appeared about 10 days before death, but no lymphocytes were found until very shortly before death and then only in small numbers, and throughout the whole course of the case not a single eosinophile was found. The red cells during this period showed practically no changes in appearance and form, and no nucleated cells were present. The condition must be attributed to the chemotactic effect upon the neutrophile cells, but the absence of the other forms of leukocytes cannot be explained with our present knowledge. [D.L.E.]

5.—In concluding their article on **gastroenterostomy**, Witzel and Hoffmann report 7 cases, and as a result of their experience they claim the following advantages for the external method: First, It is possible to inflate the efferent loop of the intestine immediately after the operation by means of the tube, thus guaranteeing the proper flow of gall and pancreatic fluid on the first day; second, adhesions forming while the intestines are held in a good position by the tube, provide for a proper future outflow of the gastric contents, so far as direction is concerned; third, direct feeding can be easily accomplished by introducing proper food through the tube. [G.B.W.]

2.—Bäumler contributes a valuable article upon the treatment of **typhoid fever** with cold water. In explaining its action he abandons the idea that it is merely the antipyretic effect that is advantageous, and is inclined to accept either some tonic influence, some stimulation of the circulation associated with increased activity of the kidneys, or some influence upon the nervous system; the latter particularly on account of the absence of severe nervous symptoms usually observed in the disease. The **statistical material** extends over the period from October, 1876, to September, 1899. Altogether there were 10,019 cases, with 95 deaths, a mortality of 9.32%. Of the fatal cases, however, 10 were moribund when brought to the hospital, and 5 died some months after apparent recovery, from the disease of tuberculosis. If these are excluded the total mortality was 7.9%, not differing greatly from that obtained by others in other parts of the world. Among the cases of death were 18 cases of perforation, 7 of intestinal hemorrhage, and 2 of other intestinal disturbances, 19 of bronchopneumonia, 6 of croupous pneumonia, and 1 of hemoptysis. There were 17 cases of sepsis, 2 of diphtheria, 9 of heart-failure, 2 of embolism into the pulmonary artery, and 2 of endocarditis. In addition, 5 patients died with pronounced nervous symptoms and 5 of tuberculosis. Deaths due to invasion of the respiratory system are of course due to inspiration of infectious material. This is greatly favored by dry conditions of the patients' mouths. Bäumler is in the habit of preventing this as much as possible by placing a few layers of gauze moistened with glycerin water over the face, or by allowing a steam spray to play in the immediate neighborhood of the

patient. There are a number of interesting clinical histories of patients in whom death was due to cardiac disturbance, and Bäumler notes that high frequency of the pulse may occur in the very beginning in young persons suffering from pulmonary disturbance, anemia, or obesity. Regarding the treatment, the patients are given a bath every 2 hours when the temperature is 39.5° in the axilla. The temperature of the bath is first 28°, then 24° or 20°. The exact temperature, however, depends largely upon the individuals. Alcohol, usually in the form of red wine containing 6 to 9%, is given throughout the course of the disease in quantities of one-half to three-quarter liters daily. In severe cases a little ammonia may be added to this. Among the cardiac tonics are camphor, ammonia, and, in very severe cases, musk. Bäumler is liberal in his nourishment, giving in general milk, but when the patient objects to this, coffee, cocoa, soup with egg, beef-tea, and sometimes expressed meat-juice. The patients are always allowed to have as much cold water as they will take. In conclusion he believes that the cold-water treatment has a prophylactic value, prevents weakness of the heart, the paralysis of the central nervous system, and probably protects the tissues by reducing the fever. The chief value of the treatment is probably the prevention of complicating infections. It is therefore important to commence it as early as possible. [J.S.]

3.—Heller believes that the following conditions are essential for any method designed to **cure or assist tuberculosis**. It must not be injurious, it must aid the patient, it must be as simple as possible and act upon some rational basis. For tuberculous ulceration of the larynx, or in fact for tuberculous ulceration anywhere, the first essential is cleanliness. This may best be obtained in the larynx by careful lavage, which may be accomplished with warm solutions of sodium chlorid played upon the glottis or into the larynx itself through a small tube that is preferably led through the nose. This acts in various ways. It moistens the secretion, separates it from the mucous membrane, and gives rise to sufficient irritation of the upper air-passages to produce vigorous cleansing coughing. He quotes as an illustration the history of one of his cases. He concludes with certain reflections upon the treatment of pulmonary conditions, believing that even for improvement it is essential that the purulent softened lung-tissue must be eliminated as thoroughly as possible, and must not be inhaled further into the lung either as a result of treatment or of forced inspiration. In fact it is essential that the disease-element and its products should be eliminated by the route by which they entered, that is, by the air-passages. [J.S.]

4.—Leube, in a thoughtful and valuable paper, calls attention to the various methods by which **certain portions of the body can in some way counteract the effects of disease in other parts**. He recognizes three methods by which this can be explained: (1) Supposing an organ to be partially diseased, the parts remaining healthy act with increased vigor, and therefore accomplish by themselves the functions of the whole; (2) by the development of activity in organs whose functions are approximately the same as that diseased; (3) by the increased activity in certain organs that remain healthy, but which have not functions similar to that diseased. Regarding the first type, he calls attention particularly to such a condition as hypertrophy of the heart-muscle or of the muscle of the gastrointestinal tract as a result of increased work. For the second there are quite a number of examples, thus—the skin under certain circumstances may assume the functions of the kidney, and it may even be desirable to increase its activity by drugs or other measures. Leube, however, calls attention to the danger of aiding diaphoresis in cases of general anasarca for fear of concentrating the fluid that remains in the skin, and therefore the amount of the deleterious substances that it contains. On the other hand, when there is no edema of the skin, active diaphoresis is indicated. Another example is the capacity of the stomach and intestinal tract to act reciprocally for each other. Thus, the functions of the stomach can be destroyed by the absence of sodium chlorid from the food, and yet proteids are digested; or the stomach may be removed, or, as a result of disease, have absolutely no normal secretion. Another example is the hypertrophy of certain blood building organs in cases of anemia, such as the spleen, bone-marrow, etc. As examples of the third type he instances the increased activity of the eliminative organs, such

as the skin and kidneys in cases of collections of fluid in the pleural or peritoneal cavities. The elimination of bacteria by these organs. Leube, as a result of a case occurring under his observation in which the patient was relieved of a considerable ascites by a sharp attack of salivation, has endeavored to study the effects of pytalism upon various forms of exudates. He usually employed for this purpose pilocarpin and found that it is often of considerable value. [J.s.]

5.—Bauer reports a case of **acute hemorrhagic poly-myositis** occurring in a man 39 years of age which commenced with severe pains in the muscles of both legs. Subsequently, the calves became swollen; there was loss of appetite, and more or less insomnia. The spleen and liver were slightly enlarged, the heart-tones weak, and there was some swelling of the inguinal and cervical glands. The temperature was very slightly above normal, not exceeding $98\frac{1}{2}^{\circ}$. Other muscles became swollen, the pain was excessive and narcotics failed to give relief. Finally, about nine weeks after the disease commenced, the patient died quietly. At the autopsy the spleen and liver were found enlarged, the former was soft, the kidneys showed the changes of acute glomerular nephritis. Microscopically, the muscle-fibers showed more or less degenerative change, increase in the number of nuclei, and interstitial hemorrhages. There was also extensive round-cell infiltration in the muscles. Pure cultures of the *Staphylococcus pyogenes aureus* were obtained. [J.s.]

6.—v. Hosslin has undertaken to determine some of the **phenomena of the circulation** by application of certain theoretic formula based upon the data obtained by various experiments. He starts out with the assumption that in animals with similar internal organization, the mean amount of oxygenation of the blood in a unit of time is in direct proportion to the area of the cross-section of the mass of the body, that is to say, the relation may be expressed by taking the cube root of the square of the body weight; thus, as an example, a mouse will employ proportionately 29 times as much oxygen as a horse that weighs 24,000 times as much as it does. Of course, this implies that the relative proportions in the amount of blood expelled from the heart in a given unit of time is the same. In small animals, however, the pulse-rate is very much more rapid. Therefore, to accomplish a single contraction it is not necessary for the heart of the animal to be proportionately as large as is the heart of one of the larger animals. The blood-pressure is after certain modifications proportional to the mean body-weight. v. Hosslin has undertaken to make careful measurements of the size, length, and number of the capillaries in the muscles of various animals. The vascular system was injected with gelatin and then allowed to remain open for some time in order that the capillaries should return to their normal size. These injected capillaries then were carefully measured, and it was found that in all cases the diameter corresponded closely to that of the diameter of the red blood-corpuscle of the animal. The length of the capillaries was difficult to determine because it depended entirely upon the state of contraction of the muscle in which they were found. The unity of measurement adopted, therefore, was the transverse striation in the muscle-fiber, and as long as this exceeded 18 there was no tortuosity of the fiber. Very numerous observations showed that the proportion of the capillaries depended upon the mean amount of work performed by the muscle concerned. In similar muscles of different animals the length of the capillaries depended upon the size of the animal. In different muscles of the same animals it depended upon the amount of work performed. The arrangement of the capillaries was curiously similar in all the animals examined. v. Hosslin then enters upon a series of theoretical considerations concerning which we must refer the reader to the original. He criticises the results obtained by Zuntz and Tigerstedt who attempted to determine the amount of work performed by the heart in a second of time, claiming that a simple calculation will show that these results are very much too low. His own method is to determine the amount of oxygen used in the course of a day by the animal, the amount of blood which must be sent through the lungs in order to absorb this quantity; then, knowing the pulse-rate, it is easy to calculate the amount of blood drawn out in a second of time. Thus, a man weighing 64 kilograms uses 720 grams of oxygen in a day, that is, 0.5 of a gram in a minute, and in one contraction of the heart .0007 grams. This requires 9.1 grams of hemoglobin or 76

ccm. of blood. Of course the quantity of blood thrown out in a given period of time varies very considerably, depending upon the amount of work that is required. [J.s.]

7.—Stumpf reports two cases of **extrauterine pregnancy**, the first occurring in a woman, 35 years of age, who was brought to the clinic on account of irregular but persistent metrorrhagia. Examination under ether showed slight enlargement of the uterus and a tumor in the posterior vault of the vagina on the left side, apparently about the size of an egg. Nine days later, a second examination showed that the tumor was considerably larger, and a diagnosis of extrauterine pregnancy was made. The tumor was punctured and a small quantity of morphia injected. The symptoms rapidly improved. The second patient, a woman of 34, had profound menstruation and severe vomiting. Finally, fetal movements were felt as far upwards as the border of the ribs. The patient was profoundly anemic. There was a large tumor in the abdomen, somewhat irregular, and in part fluctuating. There were no fetal heart-sounds. The uterus was distinct from the tumor. A median incision was made and the sac found just beneath the peritoneum filled with offensive, gangrenous material. The patient recovered. In discussing these cases, Stumpf calls attention to the fact that if after repeated examination the tumor increases steadily in size, it is to be assumed that the embryo is still living. He advises treatment with morphia injection, and believes that in early cases of ectopic gestation; it is a desirable procedure, particularly when it can be performed through the vagina. [J.s.]

8.—Schreiber contributes an excellent discussion of the **treatment of obstruction in the intestinal tract**. Discussing the possibility of cure without surgical intervention, he states that the fact, apparently demonstrated by statistics, that one-third of the cases recover as a result of internal treatment, is likely to lead to some disastrous results. It is easy to understand how the neuropathic forms recover, but in those cases in which there is distinct mechanical hindrance that can only be relieved by the knife, an operation is indispensable. It is astonishing to note the number of cases that actually die. Statistics apparently show that at least 4,000 deaths occur in Germany in a year from this cause alone. At any rate, under the most favorable conditions at least two-thirds of the cases depend exclusively upon surgical treatment. Schreiber recognizes 3 forms of this condition—(1) acute strangulation; (2) obturation; and (3) paralysis, such as occurs in peritonitis. Strangulation is characterized by sudden development of severe pain usually after violent exertion. The patient is depressed, flatus ceases to be discharged, the pulse is small and frequent, and collapse rapidly develops. The coil of intestine that is obstructed rapidly becomes distended as a result of the decomposition of its contents, and occasionally there is an effusion of liquid sufficiently large to be recognized by palpation. So long as the individual coils can be percussed, complete paralysis of the wall of the muscle does not occur. The introduction of the entire hand into the rectum is to be deprecated. In obturation, the intense initial symptoms are usually absent, the coils of intestines are distended and show pronounced peristaltic contractions. These contractions often occur in separate attacks accompanied by pain. Often in these cases it is possible to distinguish the presence of the tumor. In the paralytic form of absorption, the enormous distention of the abdomen, the absence of any form of peristalsis, the collapse of the patient, are sufficient to determine the diagnosis. Schreiber then goes on to describe the various conditions that give rise to these different forms. The commonest cause of obstruction is the encapsulation or strangulation of a hernia. The most interesting cases are occasioned by the fact that small loops are sometimes obstructed, although the great mass of the hernia remains free. He reports a number of cases with the results of operation. Another cause of peritoneal adhesion is pseudo-ligamentous bands. In some cases these may be due to tuberculosis, to pelvic inflammation, or to abdominal tumors, and cases are described illustrative of some of these conditions. Meckel's diverticulum sometimes is the cause. Another group of causes is due to the twisting of the intestines upon the axis, that is volvulus. The majority of these cases occur in the sigmoid flexure, 45 of the 76 collected by Leichtenstern. Among the foreign bodies causing the obturation are intestinal stones, and one curious case in which the patient was in the habit of

swallowing pebbles for the purpose of winning bets and from whom 403 stones weighing altogether 2,200 grams were removed. Gallstones rarely produce this condition. The commonest form of the paralytic type is peritonitis, and this is usually due to inflammation around the appendix or cecum, of which a number of cases are reported. Finally, Schreiber discusses the neurotic form of ileus, of which the most important characteristic is the slight disturbance of the general condition. Among the mechanical conditions that can give rise to it is twisting of an ovarian cyst upon its pedicle. An interesting case of this nature is described. The remainder of the paper is concerned with the technic of the operation and discusses the methods suggested by various authors and the various complications and difficulties that may occur in the course of treatment. Unfortunately, it is impossible in a brief abstract to mention all the interesting points to which the author refers. [J.S.]

9.—Kopp believes that the evidence upon the question of the relation of lupus erythematosus to tuberculosis may be grouped under five heads: First, clinical; second, histological; third, the results of inoculation; fourth, of autopsies; and, fifth, the effect of treatment. It is unquestionable that many cases of lupus erythematosus have or develop tuberculosis. This may be explained in part by the great frequency of tuberculosis; second, that the patients suffering from this disease are apt to remain secluded, which is usually a powerful predisposing factor. With the exception of two authors, none has found the histological characteristics of tuberculosis in the excised tissue, that is—neither tubercle-bacilli nor giant-cells. Inoculation experiments have been entirely negative. The one positive case of Leloir was regarded by that author as being really a case of lupus vulgaris. In many cases that come to autopsy, tuberculosis is found in the internal organs, but this is no more significant than its clinical demonstrations. Finally, treatment seems to be equally futile as for lupus vulgaris. He reports 7 cases that bear upon this question. The first, a man with a somewhat atypical eruption, died 22 years later, and at the autopsy not the least trace of tuberculosis was found in any of the organs. The second, a young woman of 23, developed also an atypical eruption which was, however, examined by numerous dermatologists who agreed with Kopp. She was weak, had frequent attacks of apical catarrh, and died of pulmonary tuberculosis. The third case, a woman of 43, had suffered some years previously from tuberculous peritonitis. The eruption was characteristic. The fourth case, a woman, suffered for years with characteristic eruption on the face, and at the autopsy tuberculosis of the bronchial lymph-glands was discovered. The fifth case, after extensive scarification of the sores, developed symptoms of tuberculous meningitis from which he recovered. The sixth patient recovered after prolonged treatment. No trace of tuberculosis could be found in the internal organs. The seventh case, a woman who had nursed her husband who died of pulmonary tuberculosis, developed the eruption, but had herself no symptoms of tuberculous infection. Kopp, therefore, concludes that there is no evidence to show that lupus erythematosus is associated etiologically with tuberculosis. [J.S.]

10.—Stintzig reports 2 interesting cases of epilepsy associated with heart-disease. The first was in a girl of 23 who was under observation for 7 years until her death. Five years before admission to the hospital, she had been run over by a wagon and had the left arm broken. The wheel also passed over the breast, and from this time she suffered from palpitation of the heart and dyspnea. Some time after this, she began to have typical epileptic attacks. Under bromids, these diminished somewhat in frequency. Later the patient developed typical angina pectoris, and subsequently died as the result of some form of acute infection. At the autopsy the brain was normal, but there was extreme mitral and tricuspid stenosis. The second patient, a man of 32, had had epileptic attacks from his twenty-second year. When brought to the hospital, there were signs of tuberculosis of the lung, and a valvular lesion of the heart. On one occasion, when he left the hospital, he became profoundly intoxicated and died the next morning. At the autopsy the brain was normal, but there was marked mitral stenosis. Stintzig then commenced a long discussion of the possible relation of heart-disease to epilepsy. It is possible that under certain circumstances, the two diseases may be produced by the same cause, as for example, in cases of syphilis

or exophthalmic goiter. This, however, must be exceedingly uncommon. It is hardly likely that aside from acute dilation, the epileptic attack can affect the cardiac condition. On the other hand, it is possible that heart-disease might tend to develop epilepsy in a person already predisposed. Under these circumstances, it is necessary to prove that the heart-disease is present before the epileptic attacks developed, and other exciting causes must be excluded. As, however, the coincidence of the two conditions is very unusual, and as no improvement is usually produced in the epileptic attacks by treatment of the cardiac condition, it is not unlikely that the simultaneous occurrence of the two diseases is purely accidental. Of course, it is possible under certain circumstances that the epileptic attacks occur only as the result of the development of the cardiac lesion. Curiously enough, in spite of the violence of the epileptic attacks, they do not appear to influence unfavorably the presence of a severe lesion, such as was present in the first case. It appears that in certain cases a peculiar modification of the epileptic attack is produced by the heart-lesion, and they may sometimes be replaced by angina pectoris. [J.S.]

11.—Gessler, who is convinced that the initial lesion in myotonia congenita is really some alteration in the peripheral termination of the motor nerves, that is in the muscle-plates, and is associated with muscular hypertrophy, has reached the conclusion that some lesion to the nerve that would diminish its functional activity would probably cure the condition. Therefore, upon theoretical grounds, it occurred to him that stretching or even slight compression of the nerve might be of benefit. He reports a case, that of an apprentice, 20 years of age, who apparently from birth had noticed a curious loss of power in the limbs after a period of prolonged rest. If then he attempted any movement, the limb would become powerless and rigid, and he would often fall to the ground. During movement, force and flexibility gradually returned. All the muscles of the body were remarkably hypertrophied. The characteristic myotonic reaction was present. The first effort to apply novel therapeutics was made by simply over-stretching the limbs at the hips, keeping the knees straight. The patient was anesthetized and first one and then the other foot brought to a position behind the ear and kept there for about five minutes. No evil result followed. The myotonic reaction disappeared in the muscle of the calf, and the muscular movements were performed in a perfectly normal manner. Later, incision followed by stretching of the crural nerve, was performed with equally good results. About six months later the symptoms returned partially, and preparations are now being made for more complete operation. [J.S.]

12.—Eulenstein has collected all the recorded cases of ear disease occurring in patients suffering from diabetes, and reports 4 new cases, 3 observed by Körner and 1 by himself. The latter occurred in a man, 52 years of age; the others had acute purulent otitis media which was cured by paracentesis. Altogether there were 50 cases; 45 of these acute or subacute, 3 chronic, and in 2 the character is not given. In 22 cases the mastoid process was not involved. In one interesting case the patient presented all the symptoms of diabetic coma, but was rapidly cured by the evacuation of the exudate of the middle ear. The characteristic of the otitis of diabetes has always been supposed to be the rapid carious degeneration of the mastoid bone. Of course, as this is usually associated with very vascular granulations, hemorrhage is not uncommon, but cannot be considered as specific. Eulenstein, therefore, expresses himself as opposed to the view that there is a characteristic form of ear-disease for diabetes, for those in which the course is more rapid are merely the result of the weakened condition of the patient. The existence of diabetes cannot be regarded as in any sense a contraindication to operation. [J.S.]

13.—v. Hösslin reports 11 interesting cases of brain-syphilis with the treatment and its results. In nearly all of them there was a clear history, and it was remarkable what a large proportion of the cases had received thorough treatment. In 4 no treatment was employed, in 2 it was unknown or part treatment had been employed. In all the rest, inunction cures had been practised, often several times. Two of the patients died, 1 was improved, and all the rest recovered completely. The first patient, a man of 35, had several attacks of unconsciousness somewhat resembling epilepsy. Ophthalmic examination showed the presence of

retinal endarteritis. Vigorous treatment produced rapid cure. The second patient, a man of 37, was profoundly neurasthenic; he also had vascular changes in the eye and was only cured after several relapses. The third patient, a man of 31, was brought to the hospital in a state of profound coma which lasted 6 days. Hösslin calls attention to the great importance of feeding these patients through the esophageal tube in order to avoid the inspiration-pneumonia. The fourth patient had Jacksonian epilepsy. The fourth developed hemiplegia and died in spite of energetic treatment. At the autopsy a diffuse cerebral endarteritis was discovered which had advanced to such a degree that cure was no longer possible. The sixth patient developed aphasia, had attacks somewhat resembling epilepsy, and there was the characteristic changes in the retinal fields. The seventh patient had the symptoms of a gumma in the region of Broca with extreme disturbance of speech and hemiparesis. There was Jacksonian epilepsy. A year after his discharge there was slight relapse from which he rapidly recovered. The eighth patient had repeated attacks of apoplexy, in the course of one of which he developed hemiplegia and died in profound coma. There was extensive vascular disease of the brain. The ninth patient had attacks of dizziness and weakness in the left arm. Some of the symptoms led to a suspicion of general paresis, but complete cure was obtained. The tenth case was interesting, inasmuch as the patient had an attack which somewhat resembled apoplexy that was associated with marked loss of memory. Under treatment he completely recovered, but a year later developed general paresis and was transferred to an asylum. The eleventh patient complained of intense pains in the head and occasional fluctuating swellings in the scalp. These usually disappeared very quickly, but finally one was observed by the physician, who excised it and evacuated a considerable amount of pus. The base was formed of a carious bone and as a result all of the tender portions of the skull were examined and cureted. Complete recovery ensued. The treatment in all of these cases was similar. Blue mass was administered by inunctions, from 3 to 5 grams being given daily; potassium iodid by the mouth in doses of 3 grams daily. The patients were also frequently placed in hot-air baths at a temperature of about 122°. After the hot-air bath, the patient was usually sponged off or douched with cold water. Hösslin is of the opinion that hot-air baths are not in the least injurious, provided that, when given to patients not accustomed to taking them, the initial temperature is not too high. Relapses were treated in the same way as the original lesion. All the cases were characterized by a very oscillatory course. [J.S.]

14.—May discusses the **sanatorium** at Planegg-Krailling which is chiefly the result of v. Ziemssen's efforts. This consists essentially of a large park, over 16,000 hectares in area, in the midst of which are two large buildings, one containing the dormitories and wards; the other devoted to administration. It accommodates about 110 patients, is restricted exclusively to males suffering with thoracic disease, chiefly of course, phthisis, and is so constructed that, as nearly as possible, perfect cleanliness may be obtained; thus, throughout the entire building the corners are rounded. At present it is necessary for the inmates to pay a small stipend for their care. The same difficulty has been experienced that has been experienced in other institutions of a similar nature; that is—the physicians are very prone to send cases in advanced stages of the disease and not to select those still capable of improvement. Of 194 patients who left the institution but who had remained there a sufficient length of time to derive some benefit from the treatment, 32 were practically cured, 89 were much improved, capable of returning to work, and the remaining 73 were either slightly improved, not improved, or grew worse. In about half these cases tubercle-bacilli were found in the sputum. Among the points to which May calls particular attention is a scheme for recording pulmonary conditions, which consists essentially in drawing the signs upon an outline of the thorax. For receiving expectoration porcelain dishes are employed, partially filled with moist turf and enclosed in a tin box with a lid that can readily be lifted. Complete plans of the institution accompany the article. [J.S.]

15.—Rieder discusses the various **defects** which may occur in the **human hand**. Among these, he includes

polydactylia, modification of the number of the fingers; **polyphalangia**, modification of individual fingers; **hyperphalangia**, that is an excessive number of segments in the finger; and finally **syndactylia**, that is the formation of the membrane between two fingers. These are all forms of monstrosities as a result of excessive development. Among the opposite conditions he speaks of phocomelia in which the whole extremity is hypoplastic; adactylia or an oligodactylia in which certain fingers fail or are too small; and finally the fusion of certain groups of bones. Apparently in a separate group he includes brachydactylia or brachyphalangia, the shortening between certain joints. He reports various cases of these conditions, in one of which there was abnormal shortening of the fourth metacarpal bone on the left hand. This was congenital and perfect compensation had practically occurred. None of the subject's ancestors had had a similar deformity. One of nine children, a daughter, has excessive deformity of both hands. The changes in this case are as follows: The right upper extremity is somewhat shorter than the left and less developed; the right hand consists apparently of two digits, one representing the thumb without nail and without joints, the other representing a finger with three phalanges. In the left hand the skeleton is fairly well developed, but the first two fingers have grown together and are of equal length with the ring finger. The right foot has four toes, but they have practically all grown together, giving rise to almost a single mass. The joints are fairly movable; the left foot is even narrower than the right, and the two remaining toes are completely grown together, and have very slight motility. Various other deformities and other formations can be detected by means of the Röntgen-rays and are described. It appears from this case that the slight defect existing in the father was inherited by the daughter and became in her much exaggerated, apparently involving all the extremities. The case represents a brachyphalangia with syndactylia. There are also general changes in the skeleton. The case essentially belongs to the atavistic formations. [J.S.]

16.—Moritz has very considerably modified a model constructed by von Basch for the purpose of **illustrating the phenomena of circulation** by an ingenious arrangement of stop-cocks, valves, and manometers. He is able not only to demonstrate the normal features, but also to determine the phenomena that are produced by various cardiac lesions and by the modifications that may take place in the general circulatory resistance. It is impossible in an abstract to give either an adequate description of the apparatus or of the results of various experiments that he describes in great detail. He gives in brief form the following results of his work upon the valvular lesions in the left side of the heart: "In every case of uncompensated valvular lesion of the heart, whether it be insufficiency or stenosis, there is on the side of the valve in the direction of the circulation a diminution in the volume of blood passing, and a decrease in blood-pressure. On the side from which the circulation comes there is an increase in the quantity of blood, that is, passive congestion and increase in pressure. The compensation of valvular lesions, that is, the restoration of the normal pressure in the vascular system, is accomplished by a corresponding increase in the activity of certain portions of the heart. This in cases of stenosis consists in greater tension during the contraction; in case of insufficiency in the expulsion of a larger quantity; therefore, in order to compensate stenosis it is only necessary for the heart-chambers involved to be hypertrophied, whereas the chambers involved in insufficiency must also be dilated." By virtue of certain laws of contraction which Moritz describes in the earlier portion of his paper, the alteration in the activity of the heart produced by any valvular lesion has the effect of so influencing the heart that a tendency immediately occurs to produce compensation. Moritz believes that by means of his model, instruction can be given very satisfactorily. [J.S.]

17.—Ziegler has undertaken a series of **experiments upon guinea-pigs and salamanders, breaking the bones subcutaneously**, and then setting them histologically at varying intervals after injury. His histological technic consisted in hardening the bones either in bichlorid of mercury or in 4% solution of a formol and then decalcifying in a solution of acid. The stains employed were chiefly hemalaun and v. Gieson's method. In the guinea-pigs, the first appearance of a cartilage in the callus was observed on

the fifth day. The periosteum in this period had become considerably thickened and an almost purely cellular tissue had developed between it and the bone. Between the cells there was found a clear hyaline basal substance, and even on the fifth day a few small columns of bone could be detected. In salamanders, contrary to Ziegler's expectation, the process develops very much more slowly, and not until the twenty-seventh day is there any marked formation of new tissue. This appears as a mucoid connective tissue filled with delicate fibrilla and a moderate number of branched cells. The formation of a cartilage appears first on the fiftieth day. On the seventy-fifth day there is slight formation of bone beneath the periosteum, but none from the bone itself. It appears that the new bone is formed from the periosteum, usually as a large medullary cavity, and is supplied with bloodvessels which grow into it from the periosteum. Before these bloodvessels enter it, however, there appears a number of fibrilla that probably give rise to colloid substance. In conclusion, Ziegler states that the **healing of fractures** is accomplished by callus that develops from the periosteum which subsequently is changed directly into bone after preliminary vascularization. [J.S.]

18.—Barlow discusses the **possibility of nonspecific urethritis**. He insists that the following conditions must be observed before its existence can be accepted. There must have been no previous attack of specific urethritis, and upon this point the history of the patient cannot be accepted; therefore, careful search of the secretion must be made for gonococci. At the same time the presence of signs of chronic specific urethritis must be determined, and all other forms of infection of the genitourinary tract, such as tuberculosis, herpes urethralis, etc. Of course, the pathogenicity or nature of any form of bacteria that can be cultivated must be determined. After a careful review of the cases of constitutional urethritis in the literature, Barlow concludes that none is completely free of these defects, and that therefore constitutional urethritis cannot be considered as proved. Neither is there any proof that urethritis can be caused by irritant poisons that may have been injected. It appears that the traumatic urethritis may be produced by foreign bodies in the urethra or by direct traumatism to the external skin. Various forms of bacteria may under favorable circumstances cause inflammation of the mucous membranes. In only one case, however, has such a microorganism been proved to be the specific cause by inoculation-experiments. All the other causes are therefore more or less doubtful. In some of these cases, including one reported by Barlow himself, although there was abundant pus-formation, bacteria could not be found. [J.S.]

19.—Sittman, after a consideration of the **inflammatory conditions of the larynx associated with edema and redness**, that is, resembling erysipelas, reports a case of a man, 48 years of age, who, as the result of fracture of the bone 2 years previously, with resultant injury, had inflammation of the leg, in the course of which he was suddenly affected with difficulty in breathing and laryngeal stridor. There was considerable cough and although respiration subsequently became freer, edema of the lungs developed and finally caused death. The mucous membrane of the larynx was much swollen, the vocal cords were thickened and partially closed. The lungs were intensely edematous; otherwise the autopsy was negative. Cultures showed only the *Staphylococcus pyogenes albus* with the exception of a few contaminations. Histological examination of the mucous membrane of the larynx showed the presence of a considerable round-cell infiltration of the submucous layer. The case, therefore, represents **secondary erysipelas of the larynx** which would probably, had the patient lived longer, gone on to perichondritis and abscess formation. Evidently, the infection took place through the blood. [J.S.]

20.—Bibler reports a case of **opium poisoning** occurring in a waitress who had taken a large quantity, equivalent to 26 grams, of tincture of opium as an abortifacient. She complained almost immediately of intense dizziness, and no physician was called until she became unconscious and there was cyanosis of the extremities. Stimulants failed to cause any reaction and she died 48 hours after ingestion of the dose. At the autopsy there were found marked evidences of putrefaction, intense congestion of the veins in the brain, but no opium could be found in the tissues; but its presence, however, in the residual bottle from which she had

drunk and the fact that this bottle was given her by a woman who admitted placing opium in it, was considered sufficient evidence of the cause of death. [J.S.]

21.—Hoflmayr combats the theory that **neurasthenia** is merely a form of exhaustion of the nerve-cells, because general observation teaches us that psychic injuries rarely produce lasting effects in healthy persons; for if this were not true we would have neurasthenic epidemics after severe campaigns, and this is not the case. More careful case-histories usually show that before the outbreak of the neurasthenia, there is usually some disturbance of the bodily functions, and that the psychic shock merely develops a condition that is latent. Among these preliminary states, excessive intellectual effort can be considered in the majority of cases as one of the predisposing causes. Healthy persons recover from it with rest, just as readily as they recover from physical exertion. All cases, however, show as a common quality disturbance of nutrition. Hoflmayr, therefore, believes that neurasthenia is a form of auto-intoxication in part due to imperfect respiration, in part to imperfect absorption of nutriment from the gastrointestinal tract. He admits, however, that it is impossible at present to say whether some specific poison is formed, or whether a variety of poisons act together to produce this result. [J.S.]

22.—Grassmann reports the case of a man, 60 years of age, who six years before had been attacked while fishing with **intense pain in the left calf** which made it impossible for him to stand. He has been an **excessive smoker** during his whole life, consuming more than one hundred cigarettes a day, and frequently used alcohol to excess. At the age of 20 he had specific infection. He had always spent a considerable portion of the day on horse-back. The attack was characterized by a feeling of numbness in the leg which then became pale, cold, no pulse could be felt, and thrombosis was diagnosed. However, the leg returned to its normal condition in the course of 20 days, and a subsequent attack involving the right leg occurred a year later, and ultimately both legs became moderately atrophied. From this time on any attempt to walk usually occasioned intense pain in both legs. This lasted a few moments and then disappeared if the patient sat down. During the intervals of pain, there was a curious subjective sensation of cold in both feet; there was moderate cyanosis in both limbs that increased if they were allowed to hang down. Vigorous specific treatment and careful massage and the application of electricity to the paresthetic areas produced considerable improvement. It is probable that in this case **arterio-sclerosis** was the chief agent in the causation of the condition, although it is difficult to understand why the syndrome of intermittent claudication does not occur more commonly when this condition or disease exists, or does not occur when one of the main arteries has been tied off. In the beginning of his paper, Grassmann calls attention to a similar condition that is noticed in horses. [J.S.]

23.—Kattwinkel reports the case of a man of 58 who had **chronic chorea** and whose father had died of the same disease. There were also other cases of mental disturbance in the family, usually of this chronic hereditary type. The movements consisted in shaking the head, twisting of the thumbs and fingers, irregular movements of the feet and legs, and occasionally a slight swaying in the chair. Voluntary movement seemed to diminish the chorea. Careful investigation of the intellectual phenomena showed that the patient was able to recognize colors, had great difficulty in recalling familiar objects, such as the flowers or birds with which he was acquainted, had difficulty in recognizing the simple geometric figures, and in general showed great difficulty in fixing the attention. Recent events seemed to be fairly well remembered, but it was almost impossible for him to commit anything to memory. Slight differences between objects were not often recalled. The second case occurred in a man of 40, apparently spontaneously. After a severe injury resulting from an assault, he noticed difficulty in walking. The movements were exceedingly irregular and almost constant. They resembled voluntary movements, such as pulling the handkerchief out of the pocket, balancing on the toes, etc. In addition there was total anesthesia to touch, pain, and temperature, loss of the sense of position and bilateral concentric narrowing of the field of vision. In view of the chronic nature of the case and the psychic disturbances, Kattwinkel does not believe that hysteria, if it exists

is more than a complication. In testing this patient, Kattwinkel utilized the division of memory into the recognition of elementary objects, the recollection of old events, of recent events, and the ability to commit phrases, etc. Passing and recent events were thoroughly well remembered, and the patient could also recognize familiar objects, but otherwise the memory was poor, indicating a deficiency in attention. In addition the patient showed an irritable disposition. Kattwinkel concludes as a result of these investigations that the psychic changes in chronic progressive chorea cannot be regarded as dementia, but simply and chiefly as a loss of attention. [J.S.]

24.—Wanner, as a result of the careful testing of various cases of unilateral deafness by whispers, ordinary conversational speech, and loud speaking, and particularly the determination of musical notes, especially the upper and lower limits of the scale that is heard, also the duration of the perception and the comparison of aerial and osseous sound-conduction, arrives at the conclusion that the diagnosis of unilateral deafness can be made under the following conditions: First, when speech is heard equally well when both ears are closed, or when the sound ear is closed and the diseased ear has not been obstructed. Second, when the lower boundary of sound-perception is in the region of \bar{a} ; when the sound of the tuning-fork is only heard in the healthy ear; when there is no persistence of perception in the diseased ear by bone-conduction. Finally, in testing the persistence of sensation of sound in the ear, it is found that in diseased ears, instead of increasing for the higher notes, it gradually decreases or disappears completely. [J.S.]

25.—Lindemann reports a case of scleroderma occurring in the right thigh, giving rise to the characteristic induration with paresthesia, which was at first treated with an arsenical water and lead plaster. This proving ineffective, energetic treatment with arsenic administered hypodermically was commenced, a solution being prepared so that one cubic centimeter equalled .01 gram of arsenic. The initial dose was .2 of a cubic centimeter (equalled $\frac{2}{3}$ grain arsenic), and this was rapidly increased to .1 of a cubic centimeter daily until a cubic centimeter was given. When there was marked evidences of arsenic poisoning, the dose was reduced and then gradually increased, and finally, after about a month of this treatment, the patient was discharged considerably improved and directed to take the arsenical water again. From this time on the sclerodermic areas were covered with reddish spots, became softer, and the subjective sensations improved. Three years later this improvement was still permanent. [J.S.]

26.—Voit has investigated the amount of acetone excreted by a dog in the urine and by the respiration in various forms of diet. He found that increase in the amount of meat given the animal caused a considerable increase in the amount of acetone, and that this increase was not affected by adding fat or starch. During starvation the quantity of acetone diminished very considerably, and contrary to the condition found in human beings, the amount of acetone in the expired air was always considerably greater than the amount in the urine, but even under these circumstances it represented such an insignificant quantity that it was hardly worth consideration. It is possible, however, that in cases of diabetes the amount of acetone excreted in this manner may be more considerable. [J.S.]

27.—Glockner reports an interesting case: the patient, a man, had been under treatment in the hospital for gastric catarrh from 1878 until 1890, the cause being excessive alcohol. At the latter date, he commenced to complain of some impediment of deglutition, and a long stenosis was discovered 21 cm. from the edge of the teeth. Warm food was particularly difficult to swallow. In the course of a year this difficulty disappeared. In 1897 he was examined. There was no pain and no discomfort when he swallowed. Death occurred the following year, and at the autopsy the following conditions were found: a girdle-like ulcer in the lower part of the esophagus with three deep excavated areas; hypertrophy of the muscle-wall of the esophagus; multiple hemorrhagic erosions of the mucous membranes of the stomach; gastric ulceration and peptic ulcer of the duodenum. Microscopically, the ulcerated areas of the esophagus were found to be denuded of epithelium, and surrounding the tube there was hypertrophy of the fibrous connective tissue which was apparently beginning to con-

tract. The other portions of the esophagus as well as the wall of the stomach and duodenum showed the existence of a chronic catarrhal inflammation. The apparent cause of these ulcerations was thrombosis in the bloodvessels of the walls. In some instances old organizing thrombi were discovered. [J.S.]

28.—Gebhard, dissatisfied with our knowledge concerning the influence of the astringents upon the intestinal tract, has undertaken a series of experiments which were performed upon a large hunting dog in whom a portion of the intestine had been separated from the continuity of the intestinal tract and sewed in the abdominal wound, both ends terminating in fistula. Into this small loop of intestine, various quantities of fluid containing albumin, sugar, etc., were introduced at a temperature of 37° , and then at the end of 15 minutes the entire contents carefully washed out, and quantitative estimations made. Various other substances were employed; for example, tannin, alum, lead acetate, silver nitrate, and bismuth subnitrate. Serial investigations made on the same day showed that the effect of the astringents continued for some time. Alkali tannate and albumin tannate had practically the same effect. His conclusions are as follows: that the absorptive power of the small intestine is diminished by the astringents, particularly tannin; that the effect of the drug is purely local; that its action continues for some time after the solution containing it has been washed from the intestine, but the albuminates of tannin are not as effective as the pure drug. [J.S.]

29.—Wolfhügel has undertaken a series of experiments for the purpose of determining the effect of the Valsalva experiment upon the blood-pressure. He found that when tested by von Basch's aneroid sphygmomanometer there was a persistent elevation of blood-pressure which was dependent upon the depth of the inspiration made before the forced expiration, and whether abdominal pressure was employed. If the preliminary inspiration was not greater than ordinary, the increase invariably occurred, and could be made to persist for some time, if, after the expiration, several rapid and deep inspirations were made. The experiments were made upon three powerful young physicians, the measurements being made upon the temporal artery while the patient was lying supine. The pulse was counted by an assistant, and every ten seconds its rate and the blood-pressure were noted. The result showed in general that the increase of blood-pressure was in excess of the increased pulse-rate, and that the effect of abdominal pressure was to increase very greatly the blood-pressure and moderately the pulse. In some cases in which a particularly deep preliminary expiration was made there was slight decrease in the blood-pressure. [J.S.]

30.—Brauser has made a series of examinations of the urine of males entering the service of Prof. Ziemssen, in order to determine in what proportion of cases mucus or pus shreds is present. All cases of obvious local inflammatory disease, such as cystitis, pyelitis, etc., and all cases with fever or other infectious conditions, were also omitted. Altogether, 300 patients were investigated, and it was found that 163 had pus shreds and 83 had mucous shreds, and only 54 were entirely free—that is to say, at least half of the patients investigated suffered from residual deep urethral inflammation. In these cases history of infection was very rarely obtained. In only 10 cases were typical gonococci discovered. [J.S.]

When to Operate in Appendicitis.—John B. Murphy (*Chicago Medical Recorder*, June, 1900) advocates operation within the first 24 hours, since during that time the operation can be done with a maximum mortality of 2%. The danger of operation increases with time because of the escape of septic material from the appendix, infecting lymphatics in the vicinity and causing septic cellulitis and septic peritonitis, which may be of a variety not to be controlled. He thinks the diagnosis can very readily be made within the first 24 hours. If the case is past the first 72 hours when he first sees it, he frequently allows it to proceed without operation, that is, if there is a circumscribed abscess with low temperature and no indication of great virulence of intoxication. [M.B.T.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

The Treatment of Tuberculosis.—De Renzi (*British Medical Journal*, May 26, 1900), at the congress recently held in Naples, stated that putting aside prophylactic treatment and treatment in sanatoriums, the field of the therapeutics of tuberculosis was now much restricted. Of pharmaceutical remedies, two only need be considered—creasote and iodine. The former had been given in the most varied forms and doses, but the only definite effect which it produced was lessening of the expectoration; this was not to be wondered at, seeing that to obtain complete sterilization of a person of medium size in regard to Koch's bacillus, about 50 grams of creasote would be required, whereas the ordinary dose which may be given with safety is from 30 to 60 centigrams in the day. The substitution of guaiacol for creasote appeared at first to be a noteworthy improvement, but it had been found to be more toxic than creasote, while not more efficacious. With regard to the other remedy named, iodoform owes its reputation mainly to the large quantity of iodine which it contains. The sedative effect which it has on cough and the lessening of bronchial secretion are manifest; but no radical effect on the tuberculous process can be expected either from it or from other preparations of iodine—potassium iodid, di-iodoform, europhen, aristol, iodo, etc. With regard to other remedies, De Renzi said that Koch's tuberculin had a very remarkable diagnostic value which in some degree compensated for its want of curative effect. In slight cases Maragliano's serum might be useful. He thought it needless to say anything about injections of camphorated oil, igazol, etc., because they had all shown themselves of little service in tuberculosis; only somatose and sodium cacodylate had prolonged life a little. Pure air and abundant feeding were the two great remedies on which the modern treatment of tuberculosis should rest. Roustan had tried sodium cacodylate in tuberculosis. The tolerance of the remedy varied in different individuals, some not being able to bear more than 8 injections successively, while others could bear 30 to 40. The injections, the dose of which was 1 cc. in the day, should therefore be suspended from time to time for a period equal to that during which they had been carried out. As results, he had observed an increase of strength, often a diminution of fever, recovery of appetite, and in some cases improvement in the local lesions. Gatti had tried various essential oils (myrtol, eucalyptol), certain camphors and antiseptics (phenol, thymol). He usually gave one injection a day for 10 days continuously, this period of treatment being followed by 5 days of rest. As results, he claimed decided and permanent increase of muscular power, mitigation of fever and sweats, diminution of cough, modification of physical signs, increase of appetite and body-weight, and diminution of the number of bacilli.

Tannigen.—Clark (*Therapeutic Gazette*, June 15, 1900) states that in all watery discharges from the bowels, no matter what the direct or secondary cause may be—whether it be nervous or inflammatory, or from acute dyspepsia due to overfeeding as well as overstimulation, which gives flatulence with foul-smelling serous discharges—he has had recourse to tannigen in combination with bismuth subcarbonate and resorcin. In leukorrhea he has found the following combination highly efficient:

R.—Tannigen	1 dram.
Boric acid	2 drams.
Zinc sulfate	10 grains.
Fluid extract of hydrastis.....	2 drams.

Dissolve this in a cup of hot water before adding it for injection to a 3-quart fountain syringe filled with water as hot as can be borne. Use the injection at bedtime and in the recumbent position with an obturator pipe.

Treatment of Gonorrhea in the Female.—Montgomery (*International Medical Magazine*, February, 1900), recommends rest in bed, saline purgatives, and light food with local treatment as follows: Hot hip-baths twice every 24 hours, and irrigation every 2 or 3 hours with 1 in 3,000 corrosive sublimate or 1 in 2,000 formalin while the symptoms

are acute. When the pain has subsided the vagina should be swabbed out with stronger disinfectants through a speculum, 1 in 1,000 formalin, or 1 in 2,000 corrosive sublimate, and after drying, the vagina packed with iodoform gauze. Silver nitrate, 10 or 20 grains to the ounce, or ichthyol ointment, 1 part of ichthyol to 4 of lanolin, may be used to paint on the vaginal mucous membrane. The uterus should be cured at once if there is the slightest suspicion that the disease has already infected the endometrium. After curetage iodoform gauze packing to provide drainage is recommended.

An Explosive Mixture.—A correspondent (*Bulletin of Pharmacy*, June, 1900) writes the *Druggists' Circular*, has had two or three complaints that the following mixture has blown out the cork or has broken the bottle after standing a couple of days:

Tincture of nux vomica..... 1 ounce.
Dilute nitrohydrochloric acid to make 6 ounces.

Recently, having had the mixture in the store for 4 days, he was startled by a loud report, and found that the cork had been blown out, and in the violent effervescence that followed about a quarter of the contents left the bottle. The gas coming off smelled like nitric acid fumes and was inflammable. The editor is of the opinion that the decomposition is due to a reaction between the chlorinated nitrogen compounds contained in the nitrohydrochloric acid and one of the constituents of the nux vomica—igasuric acid—which Höhn regarded as a kind of tannin.

Heroin.—Floekinger (*New Orleans Medical and Surgical Journal*, May, 1900) states that he has employed heroin quite frequently during the last year in various acute affections of the respiratory tract, comprising pneumonia, bronchitis, pleurisy, laryngitis, and the respiratory complications of the acute infectious diseases. At first he employed heroin in doses of $\frac{1}{2}$ of a grain, but as these doses in several cases excited gastric disturbance and vertigo, he has of late administered the drug only in $\frac{1}{4}$ grain doses, repeated more frequently, when necessary. In none of his later cases was gastric disturbance observed. Under the influence of heroin, breathing became deeper and less frequent, and expectoration facilitated. In general, however, it took 4 days before the secretion became looser and the sputa more abundant. In some cases of acute bronchitis, a copious expectoration occurred 2 days after the administration of the drug, and on the third day recovery commonly took place. In colds it is desirable to give a strong laxative in order to cleanse the gastrointestinal tract of toxic products, and also because heroin is slightly constipating. In cases of simple colds, attended with pains in the back and limbs, heroin was prescribed in the following combination:

R.—Heroin hydrochlorid.....	$\frac{1}{2}$ grain.
Salophen.....	10 grains.
Sugar.....	3 grains.

One powder every 2 hours.

In pneumonia and pleurisy with severe pains heroin was not efficient when given by the mouth, but the hydrochlorid was given subcutaneously with excellent results. A dose of $\frac{1}{2}$ grain was injected, and repeated in 2 hours when necessary. After these injections no lassitude was observed, such as is noticed after the administration of morphin. In 6 cases of acute laryngitis heroin, neither by the mouth nor hypodermically, was so efficient as morphin. In neuralgias the narcotic effect of heroin was far inferior to that of morphin. In the dyspnea of uremia and cardiac disease, heroin acted favorably. Cases of chronic bronchitis without decided emphysema were most favorably influenced by the drug. In 3 cases of chronic bronchitis a combination of heroin with potassium iodid proved very serviceable. In asthma good results were obtained, the patients being able to sleep in the recumbent position as early as the second day. In the attack itself, however, the preparation was useless. In 2 cases of reflex cough and hysteria heroin failed to exert the least influence. The distressing cough of phthisis was influenced by the administration of heroin, although the results in the last stage were not so encouraging as in the first. The night-sweats were not affected by the drug. The circulation is entirely uninfluenced by heroin. The writer concludes that heroin is an excellent sedative for the respiratory tract, which is devoid of the narcotic effect of morphin and codein, and therefore in physiologic doses is entirely uninjurious.

A BACTERIOLOGIC RESUME OF THE SAN FRANCISCO PLAGUE.¹

By ERNEST S. PILLSBURY, M.D.,

of San Francisco, Cal.

Professor of Pathology and Bacteriology, College of Physicians and Surgeons of San Francisco, Cal.

IN a recent article, R. C. Cabot² says, "I am sometimes appalled when I see how innocently, how literally, how trustfully, physicians accept laboratory verdicts as decisive." "The bacteriologist knows that some of his verdicts are relatively final—others less so and more subject to modification, according to various other circumstances. He knows when his technic has been above suspicion, or when (either from the condition of the material furnished him, or the nature of the test attempted), his results are to be taken less seriously."

It is well known among bacteriologists that there are families or groups of bacteria, each variety of which bears a certain marked resemblance to each of the other varieties of the group. In the colon group, for instance, we have the coli communis, the para-colon, and the typhoid, each resembling the other in so many respects that it is necessary to make many cultural tests to determine the variety in hand. Again, every bacteriologist recognizes the difficulty in distinguishing, both with the microscope and with the cultures, between the true diphtheria-bacillus and the pseudodiphtheria-bacillus, of which latter there have been several varieties described.

To rely, for a positive diagnosis, on a microscopic examination of any of the bacteria known, without a knowledge of its clinical source, one must be ignorant of the similarity of these groups of bacteria. The tubercle-bacillus may easily be mistaken for the lepra-bacillus or the smegma-bacillus, and much more difficult would it be to distinguish between the human, the avian and the other varieties of the tubercle-bacillus.

The pest-bacillus we have described by Kitasato as a small, short rod, with rounded ends, of the nonspore-bearing variety; and by Yersin as a cocco-bacillus, almost as broad as long and about 2μ in greatest diameter. The *B. septicaemia haemorrhagica*, as described by Sternberg, is a small, short rod, with rounded ends, 0.3μ to 0.5μ in width and from 1μ to 4μ in length; occasionally the bacilli appear like cocci. The colon-bacillus may also answer this description, and like the above two varieties it is completely decolorized by Gram's stain.

The pest-bacilli and the *Bacillus septicaemiae haemorrhagicae* stain readily with the ordinary anilin dyes. They show as cocco-bacilli, staining more deeply at the poles than in the center and sometimes forming chains of three or four elements. Here again the colon-bacilli may show a certain similarity as it occasionally presents this bipolar staining. The influenza-bacillus is another bacillus showing this bipolar stain, though it is somewhat smaller.

As has been demonstrated by Federal Quarantine Officer Dr. Kinyoun, the *Diplococcus pneumoniae* may

easily be mistaken, after a most careful microscopic study by the most expert, for the true plague-bacillus.

To prove, bacteriologically, the pest-bacillus, it will be necessary, as I have shown above, to differentiate with cultures and with animal inoculations, between it and the *B. septicaemiae haemorrhagicae* which it so closely resembles. In Surgeon-General Wyman's description of the pest-bacillus, he states: "In bouillon, under ordinary conditions of temperature, it forms flakes or flocculi, which rapidly sink to the bottom of the flask or test-tube, leaving the liquid above clear. This is characteristic. Microscopic preparations from this bouillon show the bacilli in chains of 3 or more elements." "Haffkine has proposed to take advantage of the fact in the diagnosis of plague, he having shown that in ordinary agar-agar to which is added 2 to 3.5% of common salt, the bacilli within 24 hours undergo these degenerative changes. When grown on this media the bacillus is found to be swollen up, forming spheres, spindle-shaped or oval bodies which cannot be mistaken for any other well-known microbes." The *B. septicaemiae haemorrhagicae* produces an even cloud throughout the bouillon. No special tendency to form chains being shown.

Both of these bacteria are pathogenic to the lower animals, the pest-bacillus killing rats in 24 to 48 hours, guineapigs and rabbits in 3 to 6 days. The *B. septicaemiae haemorrhagicae* kills rabbits and guineapigs in 24 to 48 hours and the rats in 2 to 5 days, the time varying in each case according to the virulence of the germ.

Of the specific cases of supposed plague in San Francisco, that of Cheu Yee Yan, a physician and tailor, who died June 2, was reported by the city bacteriologist as the most typical form of the pneumonic variety of plague that he had seen. This patient had not been seen alive by any white physician, and the only clinical history obtainable was his friends' statement that he had been sick over a year; had been gradually getting worse under his own treatment, till 5 days before his death he took to his bed. When seen by us his lips and finger-tips were cyanotic, pupils normal, and sclera normal; there was a slight discoloration of the dependent portions of the head and trunk. The rectal temperature, $3\frac{1}{2}$ hours after death, was 102.5° F.

I removed from this man a gland from the neck and one from the groin; these were apparently the largest glands of the body, that from the neck was about 15 mm. in its longest diameter; that from the groin, about 10 mm. From these glands smears were made which showed, in apparently pure culture, microorganisms resembling, microscopically, the pest-bacilli. There was a complete decoloration by the method of Gram.

Plates prepared from the neck-gland showed two varieties of bacilli, one a gas-producer in glucose agar, the other not gas-producing. All stab-cultures taken directly from this gland showed a marked gas-production. Evidently the gas-producer could not be the pest-bacillus, so no further attention was paid to it other than to demonstrate a complete decolorization by Gram. The other variety was provisionally assumed to be the pest-bacillus, as it answered the description thus far of that germ. It was further tested as to its growth on gelatin, agar-agar, with 3% salt, agar with glucose, potato, and bouillon. There were slight differences to be noted between the growth of this bacillus and that of the pest-bacillus on gelatin, agar-agar, and on glucose-agar, while on potato and in bouillon these differences were

¹ Read in part before the San Francisco Clinical Society, June 20, and followed, after discussion, by a unanimously adopted resolution to the effect that, in the belief of the members of the society, there had been no bubonic plague in San Francisco.

² THE PHILADELPHIA MEDICAL JOURNAL, April 7.

more marked. On potato, the growth was a smooth, shiny white or waxy layer; while the pest-bacillus grows as a scanty, whitish-gray coating. In bouillon, there was a quickly formed cloud, the bouillon remaining cloudy with a fine sediment after 10 days' growth. The pest-bacilli grow in flakes or flocculi and, settling, leave the top liquid clear. On the 3% salt-agar after 24 hours' incubation, there were no involution-forms to be seen, while the pest-bacillus produces many involution-forms in this medium. The plates from the gland removed from the groin gave the above described bacillus in pure culture. Stabs taken from the gland direct into glucose-agar gave no gas-production.

To the bacteriologist, these differences are quite sufficient to throw much doubt on a positive diagnosis of plague, especially when it is taken into consideration that the bacillus just described agrees in every particular with that described by Sternberg as the *B. septicaemia haemorrhagicae*, familiarly known as the chicken-cholera bacillus.

This microorganism produced death in a rabbit in 36 hours. At the seat of inoculation there was a necrotic area about 1 cm. in diameter, the central portion of which was broken down. The nearest lymphatic gland was enlarged and broken down in the center, while the next gland in the chain appeared normal. From this enlarged gland, pure cultures of a bacillus like that obtained from the man were obtained in great abundance. The rat died in 6 days, apparently from septicemia caused by this same bacillus.

Because this bacillus is commonly known as the chicken-cholera germ, there is no reason why it should be confined to the lower animals as pathogenic. Sternberg describes it as a widely disseminated germ, and says that it is sometimes found in the salivary secretions of man. In these cases of supposed bubonic plague, it must be noted that the glands of the neck are most frequently enlarged while the glands in the groin are rarely enlarged, so that it is possible we have in the chicken-cholera bacillus the germ causing this disease, to which the Chinese seem to be so peculiarly susceptible. This germ has been found in three of the cases, to my positive knowledge, and it has been the finding of this bacillus on which a diagnosis of plague has been made.

Theobald Smith³ says: "It is not improbable that the process of making pathogenic bacteria is going on now in the animal world, to be noticed only when these bacteria have been transported by some accident from their unseen habitat to species which happen to be susceptible. Then a disease appears, and we become cognizant of the disease-germ. It is difficult to explain the incidence of certain animal diseases, especially the explosive septicemias, in any other way. It is difficult, for instance, to conceive the colon-bacillus as acquiring pathogenic or invasive properties by a saprophytic life in the intestinal tract of man without at the same time inducing immunity in the race. It is not so difficult to conceive of colon-bacilli living in such an environment in the intestinal tract of certain animals as to acquire at the same time pathogenic properties towards man. Thus, microorganisms causing acute disease are out of place or else endeavoring to create a new habitat. Disease itself is a temporary disturbance of relationship largely accidental at first, but tending to become permanent as a form of parasitism."

Continuing this theory with the germ found in these

Chinese, and considering it to be the chicken-cholera bacillus, we have a germ known to be pathogenic to the lower animals, and causing in such animals just such conditions as have been found in the Chinese, where this bacillus has been found—that is, an enlargement of the neighboring lymphatics, with death from a rapidly-developed toxemia.

To the pathologist, it is interesting to note that in the so-called pneumonic forms of plague here discovered, that there is no enlargement of the bronchial glands other than would be found in other old cases of pigmentation from an anthracosis; and that, so far as known, there has been no infiltration of the tissue about the enlarged glands which have been described as not over 2 cm. in the longest diameter, in those cases said to have represented the bubonic form of plague.

Eleven to thirteen cases of this terribly contagious disease have been reported, each of which is sporadic—that is, no possible connection can be shown between any two. What is more wonderful, not a house-mate nor even a room-mate has been infected, and this without any precautions whatever among people who live 2 to 8 together in the same small, ill-ventilated room. Neither houses nor even rooms have been fumigated, except in two instances, during the last month, and in no instance has an individual house been quarantined; but instead, the quarantine included 10 blocks, with 10,000 to 15,000 inhabitants, and in several of these blocks not a single death had occurred.

Thus we present to the world 11 *atypical* cases of the dreaded black plague, each sporadic, in a city previously free from the disease, and to which port no infected ships have arrived; each different in its clinical history, so far as clinical histories have been obtained, from that of any recorded case of plague; each different in its pathologic condition from any description of such a well-known disease; and each diagnosed by the bacteriologic examination alone, the fact of death following inoculation into guineapigs being accepted as conclusive proof of plague.

A CASE OF PRIMARY ADENOCARCINOMA OF THE GALLBLADDER WITH SECONDARIES IN BOTH ADRENALS, MELANOSIS OF SKIN (ADDISON'S DISEASE?), VITILIGO, AND HYPERTROPHY OF THE PANCREAS.

By ALDRED SCOTT WARTHIN, M.D., Ph.D.,

of Ann Arbor, Mich.

Assistant Professor in Pathology, University of Michigan.

(Concluded from page 84.)

SINCE gallstones occur more frequently in women the percentage of primary gallbladder cancer is found to be proportionately greater in women. The occurrence of gallbladder cancer is also greater in regions where cases of cholelithiasis are numerous.

Two theories are held concerning the association of cholelithiasis and gallbladder cancer: First, that the gallstones lead to the production of the new growth through irritation; second, that the concretions are formed secondarily to the cancer, the growth producing an obstruction to the outflow of bile and so favoring the deposit of biliary ingredients through concentration of the bile. The latter view is supported almost entirely by theory, the actual evidence favoring it being extremely slight. It has been shown that in secondary

³ PHILADELPHIA MEDICAL JOURNAL, April 7, 1900.

carcinoma of the liver and gallbladder with obstruction to the outflow of bile that the formation of gallstones is relatively rare. Beadles¹ found gallstones in four cases of primary gallbladder carcinoma, but none in 36 cases of secondary cancer of liver and gallbladder. The evidence, on the other hand, as shown above is in the direction of proving that the majority of cases, if not every case, of primary gallbladder cancer is associated with gallstones. The small number of cases in which the stones are not found may be explained by the supposition that the stones were originally present, but had passed from the bladder either through the duct or by perforation, or had undergone degeneration. The passage of stones is of such relatively common occurrence that it would be surprising if cases were not found where the stones had been discharged. Such cases have been reported, as the one by Quetsch, in which stones were passed through a cutaneous biliary fistula for three years before signs of cancer appeared; and another case cited in the literature of cholelithiasis of 15 years' standing terminating in cancer and on autopsy containing no stones in the gallbladder. In a number of other cases in which the bladder contained no stones there were present scars and strictures of the ducts which point to the former presence of stones. My case is a striking example of cancer developing in a patient who gave absolutely no history of cholelithiasis and on autopsy showed no stones in the gallbladder, but containing encapsulated in inflammatory connective tissue near the liver three undoubted biliary concretions composed of cholesterin and bile-pigment, the growth of the carcinoma having progressed to such an extent after the escape of the stones as to cover up all traces of the perforation.

It is also well known that gallstones may undergo disintegration and be discharged even through a narrowed duct in the shape of fine debris. A number of cases of cancer have been reported in which the bladder contained only a granular debris. Both Zenker and Ames report cases of an apparent disintegration of the calculi. Theoretical arguments have also been brought forward against the "concentration" theory; Zenker holds that the growth in the bladder and ducts would tend to prevent the entrance of bile into the bladder and so rather lessen the conditions favoring the formation of gallstones than increase them. Others hold that the small size of the bladder in the great majority of the cases of cancer is against the formation of calculi.

But one case² has been reported in which the formation of the calculus was definitely shown to be later than the development of the cancer, and this stone was not composed of bile-pigment or cholesterin, but consisted of carbonate and phosphate of lime. It can, therefore, hardly be considered a true biliary concretion, but was more probably a degeneration product.

When the possibilities of the discharge of the calculi through the ducts or through fistulous openings, or of the disintegration of the stones are considered, the number of cases of gallbladder carcinoma which are not associated with gallstones must be very small indeed. The frequency, then, of the association of these two conditions is too great for us to believe that it is accidental, and the causal relation may be accepted with safety. Indeed, the majority of pathologists now state without reserve that gallstones have a direct etiologic relation to the origin of the carcinoma.

Zenker holds that the irritation of the stones upon the mucosa of the gallbladder produces first an adenoma

which may further develop atypically into an adenocarcinoma. In my report³ of two cases of "Multiple Carcinoma" I had arrived independently at the same conclusion. In one of the cases of primary gallbladder carcinoma included in that report the origin of the carcinoma from an adenomatous polyp was clearly evident. In the second case the tumor had its origin from the cells of a mucosa which showed a polypoid hyperplasia. As further mentioned in this paper the mucosa of the gallbladder in a large number of cases of cholelithiasis without cancer showed this same polypoid hyperplasia. This development of carcinomata through the stages of adenoma, adenocarcinoma to carcinoma forms in which all gland resemblance is lost does not seem to me to have been sufficiently considered in the study of the etiology of carcinoma.

MELANOSIS OF SKIN.—(ADDISON'S CACHEXIA?)—The microscopic examination of sections of the skin taken from the pigmented areas of the body shows that the pigment is in the cells of the rete, is of a yellowish-brown color, and does not give the reaction for iron. In all respects it is similar to melanin, and from its location must be considered as such. In the connective tissue of the papillae immediately below the epidermis numerous branched chromatophores are easily seen and their pigmented processes can be seen in a few instances passing up between the epithelial cells of the rete. The small capillaries of the upper portion of the corium and in some cases as far down as the sweat-glands contain similar chromatophores in their walls. These pigment-bearing cells are certainly endothelial cells and perithelial cells, and the study of the sections leads to the impression that melanin is a product of endothelial-cell activity, being formed in the walls of the small blood and lymph vessels of the corium and transferred thence to the cells of the rete. No inflammatory or degenerative processes could be made out in these vessels. That the pigment formation here is a recent process and not an old sunburn is shown by the large number of chromatophores present.

The degree and localization of the abnormal pigmentation is at once suggestive of Addison's cachexia. That the combination of symptoms included under this term, especially those of the gastrointestinal tract, could have been separated clinically from those caused by the gallbladder condition is obviously very difficult or impossible. The degree and extent of the melanoderma were also partly concealed by the intense icterus present making it impossible to say how much of the skin discoloration was due to jaundice or to some other pigmentation. Moreover, the mucous membrane showed no characteristic markings. The microscopical study of the case, however, bears out the diagnosis of Addison's disease, as a condition of the adrenals and periadrenal tissue is discovered which, in a certain number of cases, has been found associated with Addison's.

Carcinoma of the adrenals has been observed in a number of cases of Addison's, though the proportion of such cases is small. The carcinoma may be primary in the adrenals or secondary to cancer of the stomach, mamma, etc. I have been unable to find any other case where the primary was in the gallbladder, though in 2 of the 100 cases analyzed by Musser, metastases were found in the adrenals without giving rise to symptoms of Addison's. Carcinoma of the adrenals may, however, exist without any pigmentation of the skin, as in my own experience, where one case of primary carcinoma of the left adrenal and one of

secondaries in both adrenals from a primary cancer of the stomach showed no abnormal pigmentation. Nevertheless, the association of the two conditions in a certain number of cases is, I think, sufficient justification for including this case of abnormal pigmentation among those of Addison's. The short duration of the case would also warrant the diagnosis of acute Addison's.

The careful microscopic study of the adrenals and of the neighboring tissues throws no new light upon the pathology of this cachexia. The medullary portions of both organs are almost completely replaced by carcinoma, and scattered nests of the tumor-cells are found throughout the cortex of each one. In some parts of the organ, more especially in the case of the left, large areas of medullary substance are preserved. The cells of these areas show a beginning postmortem change. In other portions the medullary tissues are represented only by bands of unstriped muscle and large nerve-trunks which show no apparent change. The capsule of the right adrenal was firmly adherent to the under surface of the liver and gallbladder tumor by thick inflammatory adhesions extending almost entirely around the organ, which, however, showed no signs of compression. The microscopical examination of this pericapsular thickening shows it to be made up of connective tissue, in the lymph-spaces of which there are everywhere nests of carcinoma cells. The unstriped muscle and fat tissue of the capsule show the same infiltration. The pericapsular ganglia are surrounded by this connective tissue, and in some cases the nests of carcinoma-cells lie just outside of the capsule of the ganglion. In one of the ganglia the capsule is thickened and there is an increase of interstitial tissue throughout the ganglion, with an increase also in the number of wandering cells, but hardly great enough to be called a small-celled infiltration.

The ganglion-cells are heavily pigmented with a greenish brown or yellowish pigment, which cannot be distinguished from the bilirubin which is found in large quantities in the wandering cells and connective tissue cells of the pericapsular tissues, especially in the fat. This pigment is arranged crescentically around the nuclei of the ganglion cells. Its color and the conditions of its occurrence lead me to believe that the pigment is bilirubin and not an autoethonous pigment. It gives no iron reaction, but in those portions of the organ which were fixed in mercuric chlorid it is distinctly grass-green in color, thus confirming the diagnosis of bilirubin. Some of the nuclei of the ganglion-cells contain large vacuoles, the nucleoli remaining clear and distinct. Others are granular and have lost both nucleus and nucleolus, the protoplasm of the cell in some cases appearing light and hazy as if undergoing liquefaction. Such cells have also lost the nuclei of their capsules. These changes occur in that part of the ganglion nearest the cancer cells.

The nerve trunks of the adrenal plexus show no apparent change. They are likewise surrounded by an increase of connective-tissue which contains carcinoma-cells. This accompanies them as far as the semilunar ganglion and solar plexus. The connective-tissue surrounding these likewise contains nests of tumor-cells which bridge over the vertebra to the left semilunar ganglion and along the left adrenal plexus to the pericapsular tissue and medullary portion of the left adrenal. No changes were observed in the semilunar ganglia or in the Pacinian corpuscles of this region. The sympathetic was not further examined.

The almost complete destruction of the medullary portion of both adrenals and the involvement of the pericapsular ganglia through increased connective-tissue growth form a characteristic picture of the pathologic changes found in the great majority of all cases of Addison's in so far as the adrenals and neighboring structures are concerned. The most important changes are undoubtedly those of the pericapsular ganglia, knowing as we do that destruction of the medullary portion of the adrenals does not in itself produce the cachexia. The findings would appear to bear out the conclusions of Alezais and Arnaud⁴ that Addison's disease is dependent upon the changes in the pericapsular ganglia and not upon those in the semilunar ganglia or in the parenchyma of the adrenals. But, as mentioned above, the case throws no new light upon any of the problems of Addison's, and is of value only as a unique example of pathologic conditions leading to or associated with this disease.

It is perhaps worthy of further note that the adrenals did not present any macroscopic evidences of the pathologic changes found in them. They were of normal size and shape, the medullary portion appeared unchanged. This failure to undergo the usual postmortem change 9 hours after death was commented upon to my class at the time of the autopsy, and both adrenals were preserved for microscopic study. According to Lewin about 12% of cases of Addison's with typical pigmentation showed no changes in the adrenals. Those cases in which this diagnosis rested upon the gross appearances only are too doubtful to be considered as evidence.

VITILIGO.—Cases have been described of vitiligo following jaundice and also of its occurrence in Addison's disease. Mathieu⁵ has reported a case of vitiligo which he regarded as "most probably symptomatic of Addison's disease." The combination of these conditions is, nevertheless, a very rare one, and vitiligo itself is spoken of in the majority of textbooks on pathology and skin diseases as being of rare occurrence.

Although the condition has been known clinically even from very ancient times, the pathogenesis of vitiligo has been but little studied, and the literature of its pathologic histology is extremely scanty. Before 1882 only a few scattering observations had been made, to the effect that the rete-cells of the vitiliginous area contained no pigment, but no description was given of changes in the corium, the bloodvessels or the nerves. Even at the present time the histologic changes in the condition are dismissed with little or no attention in the textbooks. The related condition, syphilitic leukoderma, has received greater prominence clinically because of the diagnostic value attached to it, but its histology has likewise been studied but rarely.

Apparently not until 1882 was a careful microscopic study made of skin taken from cases of idiopathic vitiligo. Then Leloir⁶ from the histologic study of two cases asserted that the disease was a trophoneurosis of the skin. In sections of skin taken from two cases of vitiligo occurring in association with chronic pulmonary tuberculosis (in the one case excised from the living body, in the other removed at autopsy) he found the skin atrophied, the epidermis thinned, and the cells of the rete destitute of pigment. The atrophic corium contained few bloodvessels and those were of diminished size. He found further that the medullated nerves of the diseased areas were atrophic or showed degenerative changes, the axis-cylinders either completely destroyed or in a

condition of fragmentation, and the medullary sheath broken up into little droplets. The condition of the nonmedullated fibers he does not mention, but, nevertheless, bases his diagnosis of a trophic neurosis upon the changes in the nerve-elements. His theory gave a great impetus to the clinical teachings concerning the nervous origin of vitiligo, and numerous cases were reported in individuals who showed also diseases of the central and peripheral nervous system.

In 1884 Ehrmann studied the skin of vitiligo from the standpoint of the much-disputed question of pigment-formation, and decided that the white patches were the result of the destruction of the chromatophores in the uppermost layer of the corium. He regarded the condition as a pigment-atrophy and his interpretation of the changes came to be accepted in the majority of textbooks on the diseases of the skin. In 1889 Wermann made investigations concerning the pigment cells in this condition and found numerous "mastzellen" containing pigment in the corium of the nonpigmented areas. He believed that these "mastzellen" were wandering cells whose function it was to transport the pigment from the corium to the epithelium, and that the absence of the pigment in the rete-cells of the vitiliginous areas was due to a failure of this transportation. Jarisch and Riehl believed that the nonpigmentation was due to a removal of the pigment by wandering cells, but could not support their view histologically. Karg believed that he saw such a removal of the pigment by leukocytes in transplanted negro's skin, and Jadassohn, Jarisch, and Schmorl found in other conditions that the regional lymph-glands contained pigment. This fact was made a strong argument for the support of the "Pigmentverschleppung" theory.

Kaposi found the rete, papillae, and papillary vessels to be normal in vitiligo. Caspary examined vitiliginous skin taken from the back of the hand with especial reference to the presence of pigment-forming cells, but was unable to find them in the nonpigmented skin.

Marc⁷ made a very careful study of the changes in pieces of skin excised from a living case of vitiligo, and his report is the most complete that I have been able to find in the literature. The results of his studies may be summed up as follows: In the vitiliginous areas there is atrophy of the entire skin, thinning of the rete, flattening of the papillae, diminution of the bloodvessels, and a narrowing of those present, atrophy of the medullated nerves, complete absence of chromatophores and of pigment, and excessive numbers of "mastzellen." The collecting of the "mastzellen" he looked upon as the result of the degenerative condition of the skin. From these changes he concludes that vitiligo is a form of skin-atrophy and not merely a pigment-atrophy, and that it is most probably of angioneurotic or trophic neurotic origin, that through the influence of unknown changes in the nervous system the vessels of certain skin-areas become atrophic, the manufacture of pigment ceases and the epidermis, since no more pigment is brought to it by the chromatophores, gradually loses its old pigment in the physiological manner through the horny layer.

The histologic findings in my case correspond in the main to those noted by Marc. In sections extending across narrow vitiliginous areas from one pigmented portion to another the examination with the low power brings out very strikingly the differences between the

pigmented and the nonpigmented skin. The pigmentation of the rete-cells ceases abruptly, there is no gradual decrease in the amount of the pigment toward the borders of the nonpigmented areas; on the other hand, there is in many cases an absolute increase in the amount of pigment immediately at the border. Coincident with the absence of pigment there is a marked flattening of the papillae; in many places these are completely atrophied, so that the upper layer of the corium is entirely flat. The epidermis of the nonpigmented areas is thinner than that of the pigmented, and the rete-cells are smaller and lower. In the corium of the nonpigmented areas there is a remarkable disappearance of bloodvessels, those remaining are very small, with partially or wholly obliterated lumina. This obliteration is due to a connective tissue proliferation or to a hyalin deposit underneath the endothelium. The atrophy of the vessels is most marked in the uppermost layers of the corium. The corium itself is thinner than that of the pigmented areas, and its connective tissue is poorer in nuclei. Its fibrils have a more uniformly horizontal arrangement, differing very strikingly from the irregularly whorled structure of the corium of the pigmented skin. The sweat-glands show no change.

On staining with orcein, according to the method of Unna-Taenzer, this horizontal arrangement is found to be due entirely to the fibers of elastic tissue, which are drawn into closely-lying parallel bundles, owing to the disappearance of the intervening collagenous tissue. The bundles run horizontally to the surface of the skin. They are so numerous that the impression is obtained of an actual increase in the number of elastic tissue fibrils, but I am not able to say that this is true. There is as sharp a break in the arrangement of the elastic tissue as there is in the pigmentation, and the horizontal arrangement is coincident with the loss of the pigment. It is evident that the collagenous tissue is chiefly affected in the atrophy of the corium.

No chromatophores can be found in the corium of the nonpigmented areas. There are very few leukocytes in these areas, and none containing pigment were found. I have seen nothing which would lead me to believe that there was a removal of the pigment by wandering cells.

The staining for "mastzellen" with dahlia and methylene-blue did not reveal any unusual collection of these in the vitiliginous areas, but in sections stained with Unna's polychrome methylene-blue large numbers of cells showing reddish granules in their protoplasm are found in the corium of the nonpigmented regions. These cells have large protoplasmic bodies, are for the greater part irregular in shape, possessing long branched processes, and have oval or spindle-shaped nuclei. No distinctive differences can be made out between their nuclei and those of the other connective-tissue cells of the corium. The protoplasmic granules are large, in some cases larger than those of eosinophile leukocytes. The coarser granules are usually grouped near the nucleus, but they may also be found in the processes.

These cells are most abundant near the vessels and are found in their walls just outside of the endothelium. They are also found throughout the corium away from the vessels, but always most numerous in the upper layer beneath the epidermis. Few of them are found in the corium of the pigmented areas. A few cells of the same size and shape with granules staining blue with the polychrome methylene-blue are found also in

the corium of the vitiliginous skin. These are probably the "plasmazellen" of Unna. As in a few instances the nuclei of the "mastzellen" appear to be fragmented, I am inclined to believe that these cells are most probably degenerating connective-tissue cells. In none of them have I been able to find any pigment granules.

To sum up, the histologic changes shown in this case of vitiligo are: Atrophy of the collagenous tissue, papillae, bloodvessels, nerves and chromatophores with disappearance of the pigment; preservation and horizontal arrangement of the elastic tissue with apparent increase of the same; and the presence of numerous large branched cells showing reddish granulation with polychrome methylene-blue (mastzellen).

All of these appearances with the exception of the striking arrangement of the elastic tissue were observed by Marc. The fact that vitiligo is secondary to an excessive production of melanin in the corium must not be overlooked. The latter phenomenon cannot at present be explained beyond the theories of angio- or neurotrophic origin. The microscopic study of the pigmented portions shows an increase in the number of chromatophores and connective-tissue cells in the upper portion of the corium, evidences of an increased cellular activity. As soon as the borders of the nonpigmented areas are approached, "mastzellen" are found in numbers, and there is a general disappearance of the cells of the corium. From these findings vitiligo would appear to be an atrophy of the more highly specialized cells of the corium secondary to an increased activity of the same.

HYPERTROPHY OF THE PANCREAS.—The lobules of the organ are enlarged in comparison to those of normal cases. This enlargement is due partly to a slight increase of the intralobular connective tissue, partly to small collections of leukocytes throughout the lobules, but chiefly to a true hypertrophy of the parenchymatous cells. These are well preserved throughout the gland; there are no evidences of postmortem change found in any part. The majority of the alveoli are larger than normal; in many of them a distinct lumen is seen. In the majority of cases the central part of the alveolus is filled with a hyalin, homogeneous substance which frequently shows a vacuolation and occasionally containing leukocytes. The nuclei of the alveolar cells are large and deeply staining; the protoplasm is finely granular, staining but slightly with hematoxylin. No star or spindle-shaped cells are to be seen in the central portion of the alveoli.

The areas of Langerhans are in many cases 2 to 5 times the size of those usually seen in the pancreas. Such enlarged areas consist of convoluted cords of cells having in some cases a slight lumen, in a few instances appearing cyst-like. This is lined with endothelium, and in some cases contains blood; in others a finely granular precipitate. The chief part of the enlargement is due to the dilation of these blood or lymph-spaces. The nuclei of the cells of the areas are smaller than those of the alveolar cells, but stain more deeply; the protoplasm is much less granular and takes but little stain with hematoxylin. The connective-tissue framework of the enlarged areas is also more prominent than usual. Wandering cells are found both in the cords of epithelial cells and in the interstitial substance. These appearances in many ways are similar to those found by me in the pancreas of a case of hemorrhagic pancreatitis with fat-necrosis.

The bloodvessels of the organ show moderate congestion; this is most marked in the interlobular adipose tissue. The collecting ducts show no change. The interlobular connective tissue is not increased and the adipose tissue is not in excessive amount. There are small foci of small-celled infiltration in the fat-tissue, and occasional small hemorrhages from the distended capillaries. There is also slight edema of the interlobular tissue. No fat-necrosis was seen. Metastases of the gallbladder tumor could not be found, though these were abundant in the neighboring lymph-glands and about the nerve-structures behind the pancreas.

The existence of a true hypertrophy of the pancreas is denied by most authors. Orth and Lancereaux express the common opinion when they say that hypertrophy of this organ is extremely doubtful, the reported cases of enlargement being inflammatory in character. There is without doubt an acute pancreatitis in my case, but the slight edema, hemorrhages, and small foci of leukocytes are not extensive enough to account for the greatly increased size of the organ. Moreover, the fact that the lobules and with them the alveoli and areas of Langerhans are actually hypertrophic, makes this feature of the case much more important than the slight inflammatory changes present. The hypertrophy outweighs the latter in importance, and must, I believe, be considered as a primary condition and not secondary to the inflammation. The increased size of the cells, the enlargement of the lumen of the alveoli and of the areas of Langerhans point to an increased glandular activity. It is possible that this is compensatory in character, or the enlargement may be associated with the pathologic changes in the nerve-structures behind the pancreas, as has been thought to be the case in hemorrhagic pancreatitis. The infiltration of these structures with tumor-cells and leukocytes may be the exciting cause behind the pancreatic condition, and the changes in the organ may represent an early stage of pancreatitis. The same cystic enlargement of some of the areas of Langerhans was found in the case of pancreatitis with fat-necrosis mentioned above.

On the other hand there is strong clinical evidence to support the belief that the pancreatic condition is secondary to that of the liver. Korte and Riedel have both observed in operations for gallstones that the entire pancreas or portions of it, usually the head, was enlarged and much harder than normal. The latter² reports a number of cases of this nature. In 3 cases of operation for gallstones he found the pancreas to be enlarged and hardened to such an extent that carcinoma of the organ was suspected. The enlargement in these cases disappeared in from 1 to 2 years after the removal of the gallstones. In one case only was there an opportunity for a microscopic examination, and in this patient, who died after the operation, the pancreas showed a chronic interstitial inflammation. Riedel emphasizes the fact that even at operation it is impossible to differentiate between these benign tumors of the pancreas and carcinoma of the organ. Since the condition is apparently dependent upon the presence of gallstones, he believes that the presence of these must be regarded as the chief differential factor.

The inflammatory enlargement, however, occurs whether the stones are in the gallbladder or the common duct. It cannot be explained by an extension of an inflammation from the biliary passages into the pancreas, and is apparently not associated with the presence of microorganisms. It does not occur in all cases

of cholelithiasis. It is difficult to explain its origin on the ground of irritation by calculi. All of the cases in which it is found presented extreme icterus. In my case no stones were present in the ducts, the icterus was of recent standing due to the growth of the gall-bladder carcinoma, and the pancreatitis was slight in proportion to the hypertrophy. It is, therefore, possible that this hypertrophy is in the nature of a compensatory one, that with the abridgement of the liver function that of the pancreas is increased, resulting in a true hypertrophy. This is borne out by Riedel's cases in which the pancreatic tumor slowly disappeared after the reestablishment of the liver-function and the disappearance of the icterus. Secondary to the hypertrophy is the inflammation, which if life had been maintained longer would probably have assumed the character of a chronic interstitial process.

In conclusion, I should say that the theoretic relations existing between the various pathologic conditions found in this case are of great interest. Reviewed briefly they are as follows: cholelithiasis followed by primary carcinoma of the gallbladder, obstructive jaundice, compensatory hypertrophy of the pancreas; carcinomatous infiltration of the adrenals, melanosis of the skin (Addison's), followed by vitiligo.

THREE CASES OF TUBERCULOSIS OF THE SKIN DUE TO INOCULATION WITH THE BOVINE TUBERCLE-BACILLUS.¹

By MAZYCK P. RAVENEL, M.D.,

of Philadelphia.

From the Laboratory of the State Live Stock Sanitary Board of Pennsylvania.

THE relation existing between tuberculosis in the bovine species and man, and the danger to man from the consumption of products containing the bovine organism is one of the most important subjects before the bacteriologist and hygienist today. Bitter discussion has been waged, and extreme statements have been made on each side. Some have gone so far as to assert that residence of the tubercle-bacillus in cattle so changes its character that its pathogenic power is lost for man, and vice versa. I quote this opinion only to show the reckless extremes to which men go in the face of strong evidence, and without a single observation to support their view. I wish to enter a protest against such unsupported expression of opinion, and to say to those who belittle the danger to man from tuberculosis in cattle, that they are at least exhibiting a lack of precaution in a case where health and life are at stake, which they would consider most foolish in a money transaction, where only dollars were in the balance. The question is one which can be finally determined only by careful observation of facts and laboratory experiments, and with this end in view I wish to record the following cases of accidental inoculation of man by the tubercle-bacillus from bovine sources:

CASE 1.—Late in the year of 1896, while making a post-mortem examination on a tuberculous cow, Dr. E., a veterinarian of Pennsylvania, accidentally wounded the knuckle of his forefinger. The wound healed badly, and a nodule soon formed which showed a decided tendency to ulcerate. After some weeks he had the nodule removed and the excised portion was sent to me for examination. Unfortunately it had been kept for some 10 days in alcohol before I received it, and the diagnosis was therefore necessarily limited to the examination of sections. In the layer of tissue immediately underlying the skin was seen a mass of round cells with a considerable number of epithelioid cells, and one large giant-cell containing many nuclei arranged about the periphery. I have not been able to demonstrate bacilli in these sections in an entirely satisfactory manner, but the clinical history of the case with the histologic lesions leave no doubt that it was one of tuberculosis due to inoculation. The nodule recurred after excision and was then treated by the hot-air apparatus, which resulted in a cure. Up to the present time there has been no return of the trouble.

CASE 2.—On January 1, 1900, my assistant, Mr. G., while performing a postmortem on a goat which had succumbed to experimental inoculation with a culture of bovine tubercle-bacillus, scratched his knuckle on the broken ends of the ribs. Within a half hour the wound was washed out with a 1:1000 solution of mercuric chlorid, and sealed. It healed promptly, but about 3 weeks after became reddened, swollen, and sensitive, especially on motion. It was protected but grew worse, and on February 27 Dr. C. H. Frazier excised the nodule, with a margin of healthy skin. With one half of the nodule we inoculated 2 guineapigs subcutaneously, and the other part was prepared for sections. These sections show an infiltration-process which encroaches on the papillary layer of the skin, some of the papillae being destroyed. No typical giant-cells can be made out. None of the sections were stained for tubercle-bacilli. On May 5, one of the inoculated pigs died and the other was killed. Both of them showed a generalized tuberculosis involving the chest-cavity as well as the abdomen. There has been no return of the lesion so far.

CASE 3.—This case has been reported before, though not to this society, and the connection of the individual in whom it occurred with the Laboratory of the State Live Stock Sanitary Board, and the fact that the examination was made by Dr. Guitéras at the University of Pennsylvania, makes me feel justified in calling it to your attention. The patient is a well known veterinarian of this city, who, in making an autopsy on a tuberculous cow, wounded the knuckle of his forefinger. Between 3 and 4 weeks after, the scar was noticed to be enlarged, reddened, and somewhat sensitive. As it showed no tendency to improve, but rather grew worse, some 6 weeks after it was first noticed it was excised by Dr. H. W. Cattell, and the wound cauterized with bromin, since which there has been no return. The nodule was examined by Dr. John Guitéras, who demonstrated its tuberculous nature by finding tubercle-bacilli in sections.

The value of such cases as I have reported in proving the virulence of the bovine tubercle-bacillus for man has been questioned on the ground that the lesions resulting from inoculation are usually slight and remain localized, the conclusion being forced that the bovine tubercle-bacillus has little virulence for man. The fallacy of such reasoning is shown by the fact that the history of these accidents is that, as a rule, whatever the source of the infection, the resulting lesion remains localized, and seldom leads to systemic infection. Says Osler in his *Practice of Medicine*: "In man tuberculosis is not often transmitted by inoculation, and when it does occur the disease usually remains local."

All observers agree that the skin offers a very poor soil for the growth of the tubercle-bacillus, as indicated by the slow evolution of skin-lesions, and the small number of bacilli found in them as a rule. Chauveau failed entirely to infect calves by superficial scarifications and punctures of the skin, the nodules which sometimes formed soon disappearing spontaneously.

¹ Read before the Philadelphia Pathological Society, June 14, 1900.

Even the guineapig, which is one of the most susceptible animals known, resists invasion by the skin. In the experiments reported by Bollinger not once in six series of experiments did he succeed in infecting guineapigs by cutaneous inoculation made after the manner of vaccination, though in every case the control-animals, inoculated under the skin or into the peritoneal cavity, became tuberculous.

In general the solipedes, sheep, goat, swine and dogs resist even subcutaneous inoculation with the tubercle-bacillus, or develop a small tumor which passes away by resolution, or by abscess, no general infection resulting.

Reports of two other cases of accidental inoculation occurring in veterinarians while making autopsies on tuberculous cows may be mentioned. In one, reported by Tscherning, of Copenhagen, cure followed removal of the growth by the knife; but in the other, reported by L. Pfeiffer, the result was not so fortunate. The patient was a man of good family history and in good health. He wounded the thumb of his left hand, the point of the knife probably entering the articulation between the first and second phalanges. The wound healed without suppuration, but after six months a cutaneous tubercle formed about the scar, and the joint was attacked. The lungs became involved, and the man died 18 months after the accident. The cartilage of the joint of the thumb was necrosed, and the articulation filled with a caseous mass which was extraordinarily rich in tubercle-bacilli.

With these facts in view, it is manifestly unfair to consider the local character of the lesion produced by superficial inoculation of man by bovine tubercle-bacilli as an indication of lessened virulence for man.

The total results of comparative inoculations of tubercle-bacillus from bovine and human origin in almost all of the common animals, show a much greater virulence for the bovine organism than for the human, and until some good reason to the contrary is shown, it is fair to assume that this increase of pathogenic power will hold good for man also. The five cases given above prove conclusively that the bovine tubercle-bacillus is not devoid of pathogenic power for man, and while the number of cases is too small to enable us to draw sweeping conclusions, the indications are that, by this method of inoculation, the pathogenic power is at least as great as that possessed by the tubercle-bacillus from human sources.

A SYSTEM OF PERSONAL BIOLOGIC EXAMINATIONS THE CONDITION OF ADEQUATE MEDICAL AND SCIENTIFIC CONDUCT OF LIFE.¹

By GEORGE M. GOULD, M.D.,
of Philadelphia.

The ranchman has his annual round-up; the merchant his yearly account of stock and balancing of books; the machinist gives his engine a thorough going-over at regular intervals; every military organization has its reviews and inspections, every government its budgets—indeed, every financial hair of the commercial head is noted, and not a sparrow of the hunter. Success, falls to the ground unnumbered; those that do not fall are even more accurately numbered. But it is

not so concerning the one piece of mechanism that conditions all these things, and that is the most valuable of all earthly possessions—the human body. For all practical consideration a man's body is his life, and yet civilization has come so far without any systematization of the business and mechanics of the entire single and personal life. The science of bodily living in its complete extent still awaits its discoverer. Numberless philosophers treating of the conduct of life have soared in superficial inexactness and easy generality over the heads and hungers of the individual liver, but they have utterly failed to formulate the physiologic and pathologic conditions of success and failure. All the biologic and medical special sciences have struggled toward an unreachd unity: all are single rays, as it were, awaiting the lens of a focalizing intelligence to illumine the concrete image of our total physical appearance here. War has devised a rough and crude system of physical examinations for the would-be soldier; insurance companies have more accurately examined the bodies and life prospects of their policy-holders to estimate their financial risks; through the Bertillon system, criminology has still more perfectly fixed the anatomic measuring of the bodies of the lawbreaker; the Amherst and Harvard examinations have looked into the muscular functions of a few students for four years of their lives; the psychophysics laboratory has measured a few neurologic reactions; the medical practitioner has found out a few ways of reaching backward to the etiology of some single diseases; a few hundred school children have been subjected to some tests as to growth and the influence upon organization of poverty and wealth. But all these, I believe, are sporadic and ineffectual hints of a coming science of man, based upon a thoroughgoing and repetitive system of physiologic and pathologic examinations which will ultimately give us a genuine and all-comprising science of anthropology based upon all the data, morphologic, physiologic, and pathogenic, of the entire individual life. Prophecy and prognosis are based upon a thorough knowledge of the past and present fact, a rigid understanding in a scientific sense of the evolution of the organism and of its present departures from a normal standard. For his children a foresighted man must wish such an accounting, such a prophecy and prognosis, and as to himself every intelligent adult, when he awakens to scientific consciousness, must try to look down through the years, and reckon up his powers and possibilities of life. This most important function of provision has heretofore been left to the gypsies, the palmists, the astrologists, and the clairvoyants! Is it a wise way for science to leave the individual struggler, unconscious and ignorant of his own body and its fateful laws, incapable of learning the scattered and ununified half-sciences blindly converging to some far-off unity of mutual helpfulness and life? The crowning work of scientists is to turn Science into Prescience. The unification of the sciences dealing with the conduct of life, the making practical and useful our knowledge of the individual organism, and lastly to establish a scientific prescience,—such are the ideals of a living anthropology.

Is it not at once plain that these ideals can be realized only by a system of periodic examinations and records made every year, or every five years, throughout the life of the individual organism? Such a system of records may be held generally to comprise the following elements:

¹ Read before the Section on Medicine, American Medical Association, Meeting of 1906, at Atlantic City.

1. *The Hereditary Datum.* The endowment at birth, the influence of heredity, must in every way govern and condition the development of the organism, and modify every reaction to environment. It is wise, therefore, in all ways possible, to fix, at the opening of life, what is this datum of inheritance. Nationality, ancestral and genealogic histories, craniology, cerebrology, etc., etc., help to make up the estimate of this factor.

2. *The Developmental and Historic Record.* Especially during the period of growth (childhood and adolescence), the space between the annual or quinquennial systematic examinations should be historically epitomized. The strains, work, illnesses, and tasks conquered or incomplete, are surely a necessary part of the life-chronicle.

3. *The Morphologic or Anthropometric Examination* is fundamental. In this the Bertillon system, modified, perfected and expanded, or something similar, should form the basis of such a system of physical measurements, descriptions and records, statistic and graphic, that any future variation of the organism would be detected in later examinations, and thus would be preserved the morphologic picture of the individual for the whole life.

4. *The Physiologic Record* would include the testing and tabulation of all the significant reactions and functions. These would be made up of all necessary dynamic tests of the muscular system, of statements of accurately observed metabolic and nutritional functions, the reactions and reflexes of each of the special senses, and of those of the neurologic and psychophysiologic systems. The profound influence of habits, both positive and negative, innocent or harmful, should also be remembered.

5. *The Psychic or Intellectual Datum* is one too carelessly ignored in scientific and anthropologic studies. The fundamental qualities of character, disposition, memory, sentiment, religion, reason, morality, education, etc., are powerful influences acting upon and reacting to the environment and to disease, and if they are left out of the count a most valuable determinant of scientific prescience is lost.

6. *The Pathologic Element* is one heretofore almost or utterly ignored in anthropologic studies and in instructions as to the conduct of life. The profession should urge its profound importance. The examinations at stated periods should in large part consist of the records of the findings of expert medical specialists, secured by all the arts and instruments of diagnosis at their command. All departures from health and normality that indicate pathologic results or tendencies in any organ, or in the organism as a whole, are absolute conditions of estimate as to present powers or prospects. One is almost inclined to think the savings in medicolegal cases by such a system of examinations would defray the expenses of making them. Some time ago a railway company, after several years of legal proceedings, was forced to pay a man \$10,000 damages for intracranial hemorrhage, said to have been caused by a fall from a car. When the man died a bullet was found in his brain, received 25 years ago in the Franco-Prussian War, and this had produced all the nonfeigned symptoms, for which the railway had to pay.

7. *The Factor of Heredity* closes the circle, with the possibility of making more accurate the knowledge of the transmission of the individual endowment to the child. Successive generations are but the completing and extension of a single personality. The family is the realization of the incomplete individual.

Leaving out of consideration the questions of the

onerousness of the task proposed, and the apparent impossibility of carrying out so many observations, one may ask as to the feasibility of keeping the records of such a series. The answer to this query points to the most remarkable plasticity and adaptability of the modern plan of record-making by the card-system, with its ever-variable and extensible use of loose leaflets or cards of different colors, numbers, ear-marks, sizes, etc. Photography, the kromskope, the phonograph, the instruments of the physiologic and psychophysiologic laboratories, and those of every specialist in medicine, make it easily possible to condense the chronicles of all tests and examinations in an inexpensive and effective way. The postmortem records, and the preservation of the brains, and perhaps of the skulls, of the subjects, would supplement the work.

As has been intimated, we already have the beginnings, the sporadic attempts, and detached parts of such a system of examinations. The Bertillon criminal records of the police bureaus, the anthropometric data of military examinations, the results of athletic and gymnasium tests, those of psychophysiologic laboratories, the medical examinations of school-children, and those especially of life-insurance companies, etc.,—all these indicate the thought, labor, and expense which civilization is giving to the problem. But the most important of all contributions might be the case-books, hospital records, and patients' histories of physicians. Hardly a tithe of the precious material, however, is utilized. The waste of biologic data, wasted because not systematized and unified, in the lost records of physicians is appalling. The most valuable books in the world are the oldest city directories, scientific statistic records, etc., and more valuable still would in future years be the present-day case-books of scientific physicians, if they were well kept and illuminated by a statistical and scientific judgment. We now dump them into the pulp-mill!

Is it a foolish dream, is it an unrealizable ideal, that all these things might be preserved, and rendered of use to science and humanity by some institution carried on by the Government, by a university, or by a union of scientific and medical men, whereby the records of individual lives might be made so frequently, so continuously, and so scientifically that we should at least gather the inductive data for a genuine science of anthropology, pathology, and ethical biology? If Government could be prevailed upon to devote to this work one-tenth of the money now squandered in war; if legislators could be prevailed upon to give to it a small portion of their stealings and political plunderings; if a fraction of the money poured into the pocket of the ward and city bosses could be got; if a small percentage of that spent on comic opera could be shunted this way; if these are idle dreamings is it not perfectly possible that in future ages some wise legislator of some civilized government may convince his fellows that not only is this the duty of the national administration, but that the very beginnings of the system are already in operation in the fact of the national census-taking. In this the mechanism is really inaugurated, and needs but the inclusion of the civil-service examination, the soldiers' entrance-tests, and the governmental pensioners' medical examinations, to bring it a long way towards perfection. With the plan once determined upon, and the brain once found to gather the haphazard and discrete parts to an organismal unity, but little additional expense would be incurred over that now spent in the

separate systems. Indeed, the scheme itself is only an extended and a perfected bureau of vital statistics. Once that such cooperation were started, the city and State with their criminologic statistics, the insurance companies with their accurate vital and pathologic records, and especially the medical profession with its systematized records of individual and social morbidity, and many other agencies, would be drawn into cooperation, and the bases of a truly inductive and physiologic science of civilization would thus begin to be laid.

While we wait for that millennial palace of science we physicians need not be idle,—nay, we may be at work in the quarries. Our first duty is to reorganize, systematize, and make scientific our case-books and recordings of patients' histories. Let us study this great and neglected art so that these most precious fruits of our life-work shall not end in the pulp-mill. The lack of literary workmanship in making and keeping our records of disease is altogether deplorable. What is left to science of the life-work of a million physicians whose business has been with the most precious biologic facts of the world? Can we not perfect some bridge whereby the results of our life-labors can be carried over the stream of death and become the property of general biologic and pathologic science?

Surely, then, our second duty is to make our science prescient by means of the repeated examination at stated intervals of those patients whom we can convince of the necessity and wisdom of such a proceeding. It is a shame of medicine that in the one department of our science which we are most foolishly inclined to look down upon with too much superciliousness, its practitioners have outrun us. The dentists have long recognized the need of periodic examinations of the special organ, regardless of symptoms, and they have at last driven the knowledge into the minds of their patients. Thousands of patients have their teeth periodically examined for beginning and for preventing wants and disease. If this is wise as regards the teeth, how infinitely more wise it would be as regards the kidneys, the eyes, the heart, arteries, etc., and the person as a whole. It is the shame of medicine and the basis of quackery, this symptom-treating and symptom-killing. What a horrible fact—this of the vogue of the pain-deadeners! Millions of dollars are capitalized in the business, and half or three-fourths of the work of our lives is devoted to the mere stopping or deadening of symptoms. But, as we all know, true medicine is to stop the causes of symptoms, to prevent the symptoms from ever arising. For many years, in my specialty, I have been begging and commanding every patient to have annual or biennial ocular examinations made, regardless of "no trouble," regardless of "perfect satisfaction." Absence of symptoms is no evidence whatever of absence of disease. No eye should ever be left over two years without reexamination. No spectacles can remain correct two years, because no eye ever preserves the same refraction, balance, and powers for that period of time.

And what good, also, is the enucleated eyeball, or any piece of dead tissue, in the hands of the pathologist? Certainly only to prevent other living eyes and organs from becoming as these dead ones have become. True pathology is surely knowledge of disease in the making. The pathologist's final problem is to prevent pathologic specimens from ever coming into his hands. Quia pathologist he must commit scientific suicide. Most of our fashionable pathology is the paleontology, not the biology, of disease; but was it not said of old

that it is better to be a living dog than a dead lion? How is disease in the making ever to be discovered except by examinations, continuous observation, of the living, supposably well, organism?

Is it not even true of living disease that one-half the patients seen by the doctor are seen far too late? For paresis, locomotor ataxia, etc., and for many psychic diseases, we do nothing, because we recognize their existence so late that nothing can be done. Had they been seen earlier, injury could have been prevented. Surely in more than 25% of my patients, many years or whole lifetimes of suffering and disease could have been obviated. It is doubtless as true in general medicine. All good medicine inevitably tends to become preventive medicine; all good physicians labor to stop disease before it arrives. The whole ingenuity of the trained diagnostician is now expended on the problem of the earlier symptom. He is the greatest discoverer who discovers the presymptom, or the symptom of the symptom; the greatest therapist is he who cures before the disease exists; he who starves the bacillus to death; he who stops the evil habit, thus preventing the malfunction that finally becomes organic disease. The best cat is the one that kills the rat that eats the malt that lies in the house that Jack built. It is a truism that gout exists in the patient's system long before it causes a twinge of pain; the kidneys are ruined before the slightest subjective symptom is manifest. There may be heart-changes indicating the existence of nephritis, which a single urinalysis may not detect; arteriosclerosis may be present prior to subjective symptoms, and the objective examination would detect it; there may be unsuspected diabetes without symptoms until examination of the urine reveals it—and yet, even with our crude prescience, early urinalysis of the apparently well would often reveal the hidden evil at work sapping and mining toward the vital centers. Every oculist has often discovered albuminuria before the general physician suspected it. There are a hundred known intimations and auras of oncoming disease, but there are a thousand undiscovered ones, presymptoms, advance scouts, and forerunners, to be learned when the slight and unconscious departures from normality are studied by examinations of the supposably well. Pathogenesis, not therapeutics, is the ultimate study of all medicine. And all pathogenesis is by no means running bugs to their holes! A number of life-wasting diseases are not bacterial in origin, and even the growth of the bacterial diseases depends upon the soil in which they are sown.

I picture to myself a new field of work opening out before the poor plundered general practitioner. It must often seem to him that as general he has been stripped of both army and enemy. One by one the specialists have robbed him until he has left hardly a soldier or a patient. The surgeon first took almost a half of his army, and now threatens to relieve him of colonels appendicitis, typhoid, and heaven knows of how many more officers which he formerly considered as his very own. Then the aurist, the oculist, and the rhinologist deprived him of his special senses, and the laryngologist rendered him aphonic. If the obstetrician and gynecologist left him one or two of all his women-folk, the rest-cure man and the nerve-specialist soon alienated the affections of these hysterics—and they lived unhappily ever after. The pediatricist stole his babies, and the psychiatrist his mind; and, lastly, now the gastrologist will not allow him to have all to himself even a simple stomachache!

The truth seems to be that of all the specialists the generalist has been squeezed into the narrowest specialty, and the surgeon is grasping avidly at his one or two remaining comforts. Even the diseases of the lungs, stomach, and kidneys are now claimed, and we may soon expect to see such advertisements in the religious and daily newspapers as: "A new operation for neurasthenia; craniotomy for unselfishness; preventive inoculations in case of threatened breach-of-promise; vaccinations for antivivisectionists; damaged heart-valves surgically repaired and while you wait; kidneys transplanted immediately following the next electrocution, and complete maturation of the artificially fertilized ovum in our new twenty-first century incubator."

The family physician's function seems to be fast becoming that of adviser in general and referrer to others; the "last straw" is that ethics will not permit these others to divide their fees with him. Nothing in fact is left to him except to have permanent anorexia and to move to a climate in which house and clothing are not necessary—Porto Rico and the Philippines, for example, providentially supplied without doubt for this and similar tariff-purposes.

But, seriously, have we not gone too far with our specialism, and are we not thereby in danger of losing the coordinating sense and oversight of the organism as a whole? The specialist cannot be dispensed with. By his aid and through his accuracy medicine must progress—but neither should the generalist be squeezed aside. He is even more necessary. It is his duty to teach his under-officers, the specialists, their proper places, and by his sane and large grasp of all the facts supplied by these subalterns, by his coordination of the work of each and of all with his own overlook of organism and life as a whole, he brings cosmos out of chaos, and organic unity out of hundred-eyed and selfish diversity. The specialist is fatally inclined to treat the disease; to the generalist must be left the far more important treatment of the patient.

It may seem hard and impertinent to say to an audience of generalists that the generalists have been robbed because of their own fault and negligence. The so-called stealings of the specialists are in reality helpful, and if rightly understood they leave the generalist his proper work. Life, it has been said, is made up of little things, and yet life itself is not a little thing. So it is with health, fulness of years, and utilization of powers; they all depend, medically and physiologically, upon little things, and yet compositely, they are "the greatest thing in the world." In the vogue of the specialist, the generalist is more than ever needed. If the aristocrats have usurped power, there is the chance and demand for a powerful king. The specialists are, or may be made, the assistants of the general physician, who needs their help and all the data they can supply, and whose supreme function it is to fuse the whole to a higher unity and to establish these secret relations in reality existing in all. There is no specialist who is not willing and glad to make full and systematic reports to the general physician of all his findings. It is his duty to the patient and it is the specialist's self-interest to do it well. He is not so stupid as to offend the referrer of patients. In this function the generalist has the whip-hand—and he should use it at times.

And thus it transpires that the desirable system of personal biologic tests sketched need not await the action of Government, the university department, the city or State institute, the union of anthropologic so-

cieties, or the anthropometric and pathologic institution founded by private endowment. Let us earnestly pray and work for any or all these things, but in the meantime much may be done by medical men and societies to prepare for the larger and more perfect outworking of the scheme,—nay, much may be done toward the realization of its more distinctively medical features.

Based upon the fact acutely felt by every physician, that a series of systematized periodic examinations of patients apparently well, would often reveal beginning diseases, prevent future illnesses, and increase the vital values of life, every one can prevail upon certain patients, students, members of his family, etc., to undergo the tests, etc., necessary. The more intellectual and well-to-do citizens will soon realize the self-evident value of such work, and not only submit to it for themselves and children, but will be willing to pay an annual fee for the service. Specialists will be willing to contribute their results. The examinations may be only of the more fundamental and simple factors at first until the goodwill, machinery, funds, and recognition of the significance and usefulness of the work grow.

In several ways these examinations themselves are the means of a striking self-education of the physician:

1. In systematizing and perfecting a method of record-keeping there is a subjectively psychologic as well as an objectively scientific result of inestimable good. It is a sort of liberal education. To adapt and perfect the card system to this useful end; to summarize the results of all diagnostic methods; to formulate prognoses; to classify and epitomize so that the whole shall look to the personal advantage, as well as toward the progress of preventive medicine; and finally, to dovetail the combined result into general biologic science and a clarification of the laws of heredity—all this is labor worthy of the wisest selfishness and the best intellectuality.

2. In rendering accurate and mathematic all the known and recognized methods of medical testings, there is much to be learned. It is in catching sight of the forerunning indication of disease, the symptom of the symptom, the functional beginnings of organic abnormalism that a large deal of progress lies. Who, *e. g.*, as yet, measures the blow or stimulus in taking the patellar tendon and other reflexes, with machine-shop accuracy, and also the resultant excursion or reaction, chronicling the same in his notes with absolute or approximate precision?

3. In the excursions into the borderland but still closely related domains of cerebrology, craniology, psychophysics, criminology, sociology, public hygiene, and all the rest,—in learning to make these tests, and in chronicling the results required in these studies, one enlarges the range of his subjects, broadens his personal and scientific outlook,—in a word, annexes with justifiable imperialism and expansion the adjacent territories of his special science. Each gives his light, and, as in all beneficence, by giving each increases his own as well as the general illumination. The stars go out, but the day dawns!

Blackwater Fever in India.—Reports from the populous districts in and around Sylhet, India, show that blackwater fever has been assuming the proportions almost of an epidemic. Although it is not so rapid in its fatal effects as plague, very few cases are said to recover. Treatment seems to be of little avail.

ARE CONSANGUINEOUS MARRIAGES INJURIOUS TO
THE RACE?*By LAWRENCE IRWELL, M.A., B.C.L.,
of Buffalo, N. Y.

It is popularly believed that the intermarriage of persons nearly related by blood leads to evil consequences in the offspring, and in proof of this it has been pointed out that such diseases as idiocy, insanity, deaf-mutism, and various other disorders are much more frequently found among the children of parents who are close blood-relations than among those who are not so related. That all the imperfections above mentioned and some others are met with among the children of consanguineous marriages is true, and that they occur here more frequently than among the general population may be true; but that this condition is due to the mere fact of blood-relationship in the parents is a popular fallacy.

It cannot be said that consanguineous marriages are repugnant to nature, although custom and religious teaching have developed a repugnance thereto in civilized man. From the early history of mankind we learn that marriages between very close blood-relations were both legal and common. Abraham wedded Sarah, his half-sister; Isaac his cousin once removed; and Jacob his first cousin. Lot became the father of two powerful chieftains by his own daughters. Esau married a cousin, and Jacob married Rachel and Leah, daughters of Laban, cousins of still closer degree of consanguinity. Joseph, Judah, Levi, and Simeon were the offspring of close alliances. Jochebed, the daughter of Levi, married Amram, her own nephew, and became the mother of children who were the result of at least five generations of consanguineous marriages; and they were neither idiots, blind persons nor deaf-mutes, but one of them was Moses, the greatest statesman of his time, another was Aaron, his eloquent brother, and a third was Miriam, the prophetess.

The Persians, Tartars, and Egyptians sometimes married their sisters and their daughters; and even the members of the royal families of antiquity seem to have had no objection to the closest matrimonial alliances. The laws of the Arabs, up to the time of Mahomet, permitted consanguineous unions; and the Jews, notwithstanding the strict injunctions of Moses, continued them for a great number of years.

Nevertheless, the frequency of imperfections in the children of nearly-related parents has been noticed from a very early date, as is proved by the fact that all the great moral codes—Mosaic, Roman, Mussulman, and Christian—have alike discountenanced such unions. The Roman law, for example, prohibited marriage between ascendants and descendants, a prohibition extending to relations by adoption. In the collateral line, the prohibited degrees included brother and sister, and all cases where one individual stood *in loco parentis* to the other, as uncle and niece. This law and all the other laws upon the subject appear to have been founded on the belief, which is still generally accepted by those who have not studied the matter, that the unhappy results so often following consanguineous marriages depended upon the mere fact that parents were of the same blood. This view, however, has upon inquiry proved to be erroneous; yet this discovery has in no degree lessened the practical utility of the law forbidding the marriage

of blood-relations. In fact, I hope to convince you that there is more need of a strict observance of this rule in the nineteenth century among our highly civilized communities than there was among the primitive peoples to whom it was promulgated as a religious ordinance.

The limited time at my disposal makes it impossible for me to give you any elaborate statistics, even if anything of vital importance could be proved by mere figures. The most I can do is to draw your attention to the labors of some of the chief authorities upon this subject, and to place before you the conclusions which, in my opinion, can be legitimately drawn from the evidence at our disposal.

The following diseases have at some period in the world's history been attributed to consanguineous marriages. First come phthisis and leprosy, the true etiology of which is now known to be microorganic. Then follow idiocy, insanity, epilepsy, cretinism, hydrocephalus, abnormally-sized heads and prognathous jaws, hare-lip and cleft palate. But this does not complete the catalog, since rickets, goiter, chorea, deaf-mutism, tuberculous meningitis, ichthyosis, retinitis pigmentosa, spina bifida, albinism, hydatids of the liver,¹ dwarfing, and sterility have all been explained by the simple fact that a blood-relationship existed between the parents of the victims.

The true cause of many of the complaints which I have named is now recognized, but as I am not a physician (much less a trained pathologist), I can only refer you to the various works upon the etiology of disease which may be found in any medical library.

The earliest important examination of the influence of the marriage of near kin upon the offspring was made by Mr. August Voisin,² the French alienist, in 1865. He investigated the condition of 46 families resulting from consanguineous unions, and he showed very clearly that neither idiocy, insanity, cretinism, deaf-mutism, epilepsy nor pigmentary retinitis existed among any of these families to any greater degree than among the general population.

In 1866, Dr. Down,³ of London, selected 20 families united by the ties of consanguinity. He found 138 children, of whom 75 had average health and intellect; 28 were idiots; 8 were stillborn; 11 were "consumptive;"⁴ and 19 died prematurely. To make his observations complete, Dr. Down selected 20 other families in which the parents were not kindred, but had idiotic children. The whole number of children was 145, of whom 83 were in average health; 26 were idiots; 1 was "consumptive;" and 34 died prematurely. In all these families about one-fourth of the idiots were the first-born children, a phenomenon upon which you must place your own explanation.

As long ago as 1869, the New York State Medical Society appointed a committee to investigate the influence of consanguineous marriages, and its report, published in the *American Journal of Insanity* for 1870, leads us to believe that if the family be free from degenerative taint, marriage among its members in no way diminishes the chances of healthy offspring. The opinion of the committee is summed up in the following words: "The objection to consanguineous marriages lies not in the bare fact of their relationship, but in the fear of their having similar vitiations of constitution."⁵

In 1875, Mr. George Darwin, now professor of astronomy at the English University of Cambridge, inquired

* My original intention was to read this paper before the Sociological Section of the American Association for the Advancement of Science. Its length, however, made that course impolitic, if not impossible.

into the consequences of the marriage of first cousins, and his opinion, printed in the *Journal of the London Statistical Society*,⁷ while most valuable, is not conclusive.

His words are: "It seems probable that in England, among the aristocracy and gentry, about 4% of all marriages are between first cousins; in the country and smaller towns between 2% and 3%; and in London perhaps as few as 1.5%. Probably 3% is a superior limit for the whole population. Turning to lunatic and idiot asylums, probably between 3% and 4% of the patients are offspring of first cousins. Taking into account the uncertainty of my methods of finding the proportion of such marriages in the general population, the percentage of such offspring in asylums is not greater than in the general population, to such an extent as to enable me to say positively that the marriage of first cousins has any effect in the production of insanity or idiocy, although it might still be shown by more accurate methods of research that it is so. With respect to deaf mutes, the proportion of offspring of first-cousin marriages is precisely the same as the proportion of such marriages for the large towns and the country, and therefore there is no evidence whatever of any ill results to the offspring in consequence of the cousinship of their parents."

Mr. Darwin found no evidence that the marriage of first cousins had any effect upon the production of deaf-mutism, idiocy, or insanity, but he observed a slightly lowered vitality among the offspring of first cousins, and a slightly higher death-rate than among the families of nonconsanguineous marriages. His statistics justify, to some extent, the belief "that offspring of first cousins are deficient physically, while at the same time they negative the views of alarmist writers on the subject."⁸

The most thorough inquiry into the results of consanguineous unions was made by Mr. A. H. Huth, in 1875.⁹ His volume of 359 pages, of which a second edition was published in 1888, contains an exhaustive examination of the subject. The only work of any note which has appeared since 1875 is that of a Danish physician, Dr. Mygge (published in 1879), of which there is no English translation. Mr. Huth's conclusion is that there is no greater amount of disease or deformity among the offspring of parents related to each other by blood, than among the children of parents not so related, always provided that the parents are free from general deterioration and from tendencies to disease, conditions which, it must be admitted, are very seldom fulfilled.

Where the error lay in the old doctrine upon which was founded the prohibition of consanguineous unions, was not in asserting that disease was more often met with in the children of these than in those of other unions, which is true, but in attributing these unfortunate results to the mere fact that the parents were blood-relations. Over and above the fact that consanguineous marriages are almost certain to transmit in an accentuated form any defect or tendency to disease already present in the family, there is, in all probability, no reason why such marriages should not take place. I have said "in all probability," because the most careful investigation that I have been able to make has left me without any definite opinion upon the following question: Does such inbreeding as occurs among civilized humanity tend toward either sterility or dwarfing? The vast array of experimental evidence usually presented upon this topic, from the self-fertilization of plants, carried out by our great mas-

ter, Charles Darwin, to the prolonged inbreeding of rabbits undertaken by Sir John Sebright, has no value in determining the consequences of the marriages of blood-relations, as we are not concerned with the closest possible inbreeding.

In reference to both dwarfing and sterility, the evidence is most contradictory. One can find a considerable number of isolated communities where intermarriage has been the rule, but, in almost every instance, while one observer considers that the people are abnormally small, or are becoming sterile, another either denies those facts or discovers some different explanation of the phenomena.

Man cannot be subjected to experiments like those tried in the case of other animals, and habitual intermarriage of the nearest relatives has long ceased to be an everyday occurrence. Incestuous unions were known to have prevailed among the Egyptians and Persians; but, according to Mr. Adam,¹⁰ there is no proof that physical deterioration ensued. We must remember, however, that, among these nations, marriage did not always take place between closely-related persons; and cattle-breeders inform us that the mixing-in of even one drop of unrelated blood is sufficient to neutralize the injurious effects of long-continued close interbreeding.

Mr. Huth¹¹ asserts that, although the Ptolemies habitually married their sisters, nieces and cousins, they were neither sterile nor particularly short-lived. Mr. Galton,¹² upon the other hand, says: "The result of Ptolemaic experience was distinctly to show that intermarriages are followed by sterility."

The Veddahs of Ceylon are probably the most in-and-in-bred people that ever existed. Among them the practice of a man marrying his younger sister was the rule. Mr. Bailey¹³ tells us that it was the proper marriage. With the Bintenne Veddahs this custom may be said to have been extinct in 1865, while among those of Nilgala it was at that time only gradually disappearing. Mr. Bailey believes that close intermarriage is quite sufficient to account for the short stature as well as the weak and vacant expression of these people. But he did not find any traces of insanity, idiocy, or epilepsy—the maladies which such marriages, according to popular belief, are supposed to produce. He writes: "The injurious effects of this custom would seem to be plainly discernible. The race is rapidly becoming extinct; large families are all but unknown, and longevity is very rare."

Pitcairn Island, in the Pacific, which was uninhabited until 1790, was in that year peopled by the 9 mutineers of H.M.S. "Bounty," who brought with them 6 men and 12 women, natives of Tahiti. There were in 1878 about 125 inhabitants upon the island, and up to that date all observers agreed that they were muscular, tall, and generally healthy. I must mention, however, that during the past 50 years a few strangers have joined the colony, and that men-of-war have often visited the island.

Upon the other hand, Captain Dyke, of H.M.S. "Comus," who visited the island in April, 1898, and found that the population, which was 136 in 1894, had increased to 149, says:

"The question whether the constant intermarrying that has taken place in 107 years is physically degenerating the younger members is a very interesting one. However, one curious trait is very noticeable in them, viz., the loss of the front teeth. To be correct, the teeth

are not lost, but broken off. Some attribute this defect to the food eaten by the inhabitants, such as bananas, yams, etc., but this is not noticed among the negro races in various parts of the world, or even in the Tahitian natives close at hand, who live on the same sort of food. Again, an American missionary and his wife, who have been on the island since June, 1896, superintending the school, both assured me that the want of intellect among the young was simply appalling, and they had no hesitation in putting it down to this intermarrying. In fact, they had given up all hope of improvement, and intended leaving on the first opportunity. I was told the morals of the community were not what they should be."

Mr. Hunter, Judicial Commissioner, who visited the community recently, says:

"The children are bright, merry little things, the only redeeming feature in the place, whereas the adults, with the exception of one or two of the older ones, have a tired, hungry look, very different to what I expected to see, from accounts that I had previously read of this unique island and its people.

"They begin and end their day with prayer; they neither drink nor smoke; and they appear to be almost vegetarians. If they are questioned, the questions must be put in plain, simple language, or they do not understand."

The rugged island of St. Kilda, in the Atlantic, 40 miles from the Scotch coast, with no regular communication to the mainland, has a population of less than a hundred inhabitants, in good health, although the infant-mortality below the age of 5 is nearly ten times that of England generally. Dr. Mitchell¹⁴ attributed this condition to the continued intermarriage of a population already too closely related. Mr. Huth considers it a result of the diet of the mothers, which consists chiefly of seabirds, a very oily food. The population of St. Kilda is undoubtedly on the decrease.

Mr. Augustus Smith, for many years owner of the Scilly Isles, 27 miles off the southwestern coast of England,¹⁵ believed that the inhabitants of some of the outlying islands, who never formed external connections, had degenerated very seriously. But Dr. Beddoe¹⁶ remarks on these same islanders that "their proportions certainly give the lie to the current notion that men and quadrupeds must degenerate in small islands," and McCulloch calls them a healthy people.¹⁷

I think it best to abstain from quoting any more examples of isolated communities, as the facts always admit of more than one interpretation. In every instance it must be noticed that we have peculiarly healthy people to deal with—men and women to whom disease is almost unknown—and therein lies the secret of such marriages proving innocent of evil to the offspring. Were such unions common among the neurotic, decrepit, and otherwise degenerate dwellers in our great cities of today, the result would be very disastrous.

In the year 1851, according to Oosterlen,¹⁸ 20% of all marriages in Great Britain were unproductive; 16 years later, according to Simpson,¹⁹ 11.7% were childless. In 1884, Matthews Duncan placed the figure at 15%.²⁰ Dr. Irving C. Rosse, of Washington, in Witthaus & Becker's "Medical Jurisprudence,"²¹ published in 1894, writes: "It does not appear from the recent researches and discussions of this much-controverted subject of the marriage of near kin that consanguinity in itself has the slightest action upon fecundity. Records show that marriages of cousins are not apt to be sterile. Dr. Tidy

remarks that "whereas in the average of marriages 1 woman in 8 is barren, in those between relatives only 1 in 10 is so."

(To be concluded.)

PERITONITIS IN THE FETUS.

By J. A. PORTER, M.D.,

of Brooklyn, Mich.

I WAS called, March 3, 1900, to attend Mrs. H., aged 25, who was taken with labor pains during the early part of the day. She is a large blonde woman, and has had very good health. This was her second pregnancy. She had a normal labor about 2 years ago. She is somewhat fleshy but muscular. She has had some dispute with her husband, and left him, asserting that the great sexual appetite of her husband, who was over 50 years of age, was annoying to her. She was very considerably enlarged abdominally, and there was evidence of a large quantity of amniotic fluid. Much pain preceded expansion of the os uteri. I, however, did not rupture the bag of waters until expansion was abundantly sufficient, although it required a wait on my part of about 8 hours. There was vertex presentation, third position, and the course of labor was slow, but otherwise normal in given position until birth of the head (as far as could be noticed), but with large flow of liquor amnii. After the head was delivered the child failed to come forth and several expulsive efforts of great vigor. Aid was given by bringing down arms and shoulders. I then waited during a few more pains, and began to draw on the child carefully under the axillae. With some effort, delivery was affected, and then it was noticed that the child gave one or two unnatural inspirational movements and was dead, and in spite of the various reviving means I tried, I could not get any response.

I then noticed that the abdomen of the child was abnormally large. I found it filled with a brownish-green fluid. This full abdomen had caused the delay in the birth. I was not prepared to make a critical examination, but did as well as the light and absence of suitable implements would permit. I found evidence of peritonitis very plain in the child. The intestines were matted together with soft lymph adhesions. The mesentery was deeply congested as well as the peritoneum. Lymph of a greenish color was abundant. I could not discern any anatomic cause.

I wish this description recorded because I have not seen any description of a fetus coming to full time of birth, and giving evidence, though slight, of life, and presenting evidence of a peritonitis of recent seizure, but of sufficient endurance to show the appearances above described. The mother was taken in apparent labor 4 weeks previous to my attendance, but the pains ceased in about 24 hours, normal action at normal time succeeding. The mother is now well.

To Encourage Hysteria.—A prominent physician is advertising a book for the laity, in which the "wholly unique feature" is "to enable the user to discover at once the nature of his malady,"—"a vast cyclopedia of physiology, hygiene, and the treatment of disease." "No household is complete without a copy." If the author had been content to instruct the members of every household in matters of hygiene and physiology, it would have been well, but the attempt to instruct them in the diagnosis and treatment of disease is a very different proceeding. In hundreds of serious diseases the result will be to postpone consultation and scientific treatment until it is too late. No layman can possibly be instructed, certainly not by a book, to make correct diagnosis or institute proper treatment in such cases. The plan is also likely to encourage morbid introspection and hysteria of many kinds. It is a sad blunder that a physician should have subscribed himself as the author of such a volume.

The Honorary-Degree Business is taking on a ludicrous phase, which may save it from becoming unlimitedly stupid. Legislation has long been called in to prevent the scandalous sale of medical diplomas, and one wonders how soon the same means may be employed to prevent men from buying and institutions from selling certificates of erudition. In origin and in history the degree of Doctor of Laws, or of Doctor of Divinity, certifies that in the judgment of those qualified to know the recipient of the degree was possessed of exceptional scholarship in a certain department of knowledge. But we are fast changing all that, and the degree of LL.D., for instance, now has nothing whatever to do with erudition, but only means that the new doctor of laws has been an expert lawbreaker or a shrewd law-maker, that he has been or promises to be very generous to the degree-giver, etc. We do not understand why an electrical engineer should covet a degree in dentistry, or why an expert money-maker should wish the reputation of being an expert scholar. It is in fact incomprehensible that a political boss or a patent-medicine seller should wish to be called a doctor of laws or a doctor of medicine. If the real reasons should be published which moved the trustees of learned institutions to grant their last 100 honorary degrees, we should have all the subjects for opera bouffe desirable for the

next generation or two. There is no longer any pretense that to great erudition is due its former token of the degree. What are the scholars to do now, poor things? The worst anti-medic and profession-hater is most proud of his degree of M.D. Senator Hanna and Mayor Harrison are among this year's lot of LL.D.'s.

Dr. Thomas Story Kirkbride, Jr.—Two weeks ago reference was made in these columns to the death of an illustrious physician to whom the final summons came at a time when his work on earth, so large and so well done, was almost finished. Since then death has taken one who was on the very threshold of a career of rare promise, and for whom a host of friends had confidently predicted a life of signal usefulness. Dr. Thomas S. Kirkbride had given many faithful years to preparing himself for his work as a teacher and investigator in pathology, and seemed to be just within reach of success and renown when a fever removed him forever. Dr. Kirkbride's most striking characteristics were an intense earnestness and a boundless enthusiasm with which he quickly infected all those who came in contact with him. This capacity for infusing his spirit of zeal into others had enabled him to organize on splendid lines the laboratory of which he had charge. His death is deeply felt by the younger generation of medical men of this city, by whom he was esteemed and beloved for his sincerity, his goodfellowship, and his scholarly attainments.

Another Death by Faith Cure.—Another case apparently of malpractice by religious fanatics has just occurred in this city. The two malpractitioners have been held by the Coroner for criminal negligence in causing the death of an infant. The testimony reads like a page out of medieval literature, but it is of a kind that the public should be accustomed to by this time. This was a "faith-cure" outfit, and its apostles displayed all the primitive ideas, and indulged in all the meaningless language which are now so familiar to most readers. The Coroner did his duty in holding these men for answer before a jury, and we trust the Court will demonstrate to the public that in this country the liberty to kill children is not part of the liberty to worship God.

As we have said before, it is useless to argue with these people or with their supporters—and supporters

they have in reputable churches and among persons of some religious influence. They are lawbreakers and nothing less. As lawbreakers they should be apprehended, and allowed to meditate in solitude on the practical limitations of the liberty of conscience. That this liberty is not identical with the liberty to practise medicine has not dawned with sufficient clearness upon the minds of some of them. The days of human sacrifice have gone by, and if any degenerate and half-crazed evangelist attempts nowadays to make a shrine of Moloch out of his own personal altar, he should be suppressed. A low grade of popular intelligence can alone account for the prevalence of these various superstitious rites, and it is therefore the duty of educated men and reputable journals to unite to eradicate them. It is to the credit of the newspaper press that, as a rule, it does its duty in this matter, but this cannot be said of all the churches.

The Increase of Insanity in Philadelphia.—In his annual report to the managers of the Pennsylvania Hospital for the Insane, Dr. John B. Chapin, physician-in-chief, presents an interesting table which illustrates some phases in the real and apparent increase of insanity. The table was compiled by Dr. A. R. Moulton, senior assistant physician to the hospital, and is based on official figures. As for the Pennsylvania Hospital itself, the figures are quite uniform and do not show an increase in the number of new cases in an exact ratio with the increase of population of the city. It has been claimed that the increase in insanity in our large centers of population is seen in the indigent rather than in the affluent classes, the latter of whom, of course, pay the cost of the care of their insane. The statistics of hospitals in New York, Boston, Hartford, and Providence seem to prove that this claim is correct, just as do these figures of Dr. Moulton. It will be seen that the Pennsylvania Hospital and the Friends' Asylum, both of which mainly receive well-to-do patients, have not admitted an increased percentage of new cases from this city, but that their percentage has been less during these last ten years, with one exception (1891) than in the first year (1890) of the period. Only in the last year (1899) has the percentage again risen to what it was in 1890. At the other extreme, the Philadelphia Hospital, which receives the indigent insane only, has shown an almost steady increase in the percentage of new cases which it has received, ranging from 41% up to 60%. The Norristown Asylum, which holds a rather intermediate position, has on the other hand shown almost as steady a decrease, but this, we think, must be due to its overcrowded condition. The cases tabulated are those only which have been certified from Philadelphia. Of course they do not include either the new cases treated in private or the very small proportion of these cases which are taken from this city to hospitals outside of the State or in more remote parts of the State.

These figures go to prove that there is not an undue increase of insanity among the affluent classes—a conclusion which may have to be slightly discounted in consideration of the fact that possibly more of these patients are treated in private than formerly. On the other hand the increase in the indigent insane may be more apparent than real, for it is doubtless due in part to a greater tendency in this class to seek the hospitals, and a greater readiness on the part of practitioners to make a diagnosis of insanity.

TABLE SHOWING THE NUMBER OF NEW CASES OF INSANITY IN PHILADELPHIA, THE RATIO OF NEW CASES TO POPULATION ANNUALLY, AND THE DISTRIBUTION OF CASES TO HOSPITALS.

Year.	Population.	Annual Number of New Cases.	New Cases: Ratio of to Population.	Admitted to Philadelphia Hospital.	Admitted to Norristown Hospital.	Admitted to Pennsylvania Hospital and Friends' Asylum.
1890	1,044,894	685	{ 1 to 1525	283 .41	299 .43	113 .16
1891	1,070,104	686	{ 1 to 1560	278 .41	280 .41	128 .18
1892	1,096,914	880	{ 1 to 1245	497 .56	257 .30	126 .14
1893	1,116,424	807	{ 1 to 1385	466 .58	236 .29	105 .13
1894	1,146,936	877	{ 1 to 1307	479 .54	289 .33	118 .13
1895	1,176,447	926	{ 1 to 1259	522 .56	274 .30	130 .14
1896	1,214,467	961	{ 1 to 1264	591 .61	263 .27	107 .12
1897	1,266,977	986	{ 1 to 1285	592 .60	267 .27	127 .13
1898	1,300,489	1009	{ 1 to 1289	598 .59	270 .27	141 .14
1899	1,334,991	1013	{ 1 to 1317	609 .60	243 .24	161 .16

Average for 10 years, 1 new case to 1333 of population.

Estimated number for 1900 — 1013 new cases.

In the last three columns, the figures in the upper right-hand corners show the percentage distribution of new cases to the several hospitals in Philadelphia and Norristown, and does not include cases brought to the hospitals from the State at large, or out of the State.

The Health of the False Prophetess.—An interesting story comes from Concord, N. H., that Mrs. Eddy, the grand exalted Fakir of Christian Science, is the victim of "creeping paralysis." What creeping paralysis is, we have not the faintest idea; but if Mrs. Eddy has it, she will probably soon be convinced that there is more pathology in this cruel world than is dreamed of in her philosophy. She is reported to have an understudy, who is exhibited to the credulous devotees as the real old lady, and who answers every purpose. This story is denied by the aiders and abettors of the concern, and is said to be without proof, but it suggests some interesting thoughts. As these impostors claim not to believe in disease, they of course would not hesitate to deny its existence in Mrs. Eddy, even though she were at the last gasp. This would be a casuistry of which they would be quite capable; therefore, their testimony on the subject would be most untrustworthy. There have even

been rumors that the false prophetess is dead, and that her quondam fellow conspirators have been keeping up a fake sanctuary behind the veil, somewhat after the manner, we presume, of the veiled prophet of Khorasan. The health of this woman is, of course, not a matter of public concern, except as she and her followers have chosen to make it a test for the validity of her foolish doctrines. In the order of nature she will some day die, and then, perhaps, her cult will gradually die out;—but even this is by no means certain, for this country is such a hotbed for crude half-baked doctrinaires that possibly some one will be found to perpetuate the schemes of the defunct but still immortal priestess of pseudo-religious quackery.

Goethe's Relation to Medicine.—The almost universal celebration of the one-hundred-and-fiftieth anniversary of Goethe's birth all over the German empire, and, one may almost say, all over the world, last year, brought out many interesting facts with regard to his life and work. We have just received an interesting pamphlet with the above title by Dr. P. H. Gerber, of the University of Königsberg (published by Karger, Berlin, 1900), in which many facts of special interest to the medical profession are given. Attention is called to the sturdy ancestry from which the poet was descended, his grandparents on both sides all having lived to be 72 years or over. We are told that through the lack of skill in the midwife the world came near losing a great genius. Goethe was a blue baby and at first looked so black and lifeless that there was thought to be no hope of resuscitation. This accident of his birth was not without its good influence, however, for, taking a lesson from this his grandfather helped to introduce a law making instruction of midwives compulsory. The next incident of medical interest was an attack of smallpox of unusual severity, during childhood, the entire face and body being completely covered with pustules so that the child was unable to see for several days, and we are told the dried secretion came off the face like a mask; however, he was not greatly pitted. This illness led Goethe, in later years, to use his best influence to promote the introduction of inoculation against smallpox, a second service of considerable importance to medicine. As a result of unsuitable diet, much drinking of heavy Merseberger beer and the use of large quantities of coffee during student days, Goethe suffered a severe illness during which he lost considerable quantities of blood. There is a difference of opinion as to the source of hemorrhage, some believing that the attacks of indigestion indicated gastric ulcer as the cause, while others believed that it came from the lungs; the fact that Goethe suffered from suppurating tuberculous glands of the neck at about this time seems to give some support to the latter view. The influence which led Goethe to take a personal interest in medicine and natural history began at Leip-

zig, but it was chiefly at Strassburg University, where he began his studies in 1770, that this interest was cultivated. In Leipzig Goethe associated much with students of natural history and medicine and lived in the pension of Hofrat Ludwig, where he heard little but medicine at the table. But at Strassburg the influences were even stronger; the medical faculty at this time had reached the highest point of fame, and Goethe studied just enough law to pass his examinations successfully but devoted his best efforts to the study of chemistry under Spielmann, anatomy under Lobstein, who has been called by Virchow the greatest anatomist and surgeon of that time, and besides this he attended the clinics in internal medicine by Ehrmann. Meisner, in a paper on Goethe as a jurist, has expressed the opinion that probably he would have made as good a physician as he was a bad lawyer. From his interest in these studies it seems not at all improbable. In later years, during his residence in Weimar and Jena, Goethe was in constant association and correspondence with the most eminent anatomists of the time and was specially interested in those studies in osteology which afterward led him to his discoveries with regard to the intermaxillary bone and to his theory that the skull is composed really of metamorphosed vertebrae. These studies were closely allied to those in botany with regard to the metamorphosis of plants. Gerber has even inclined to credit him with the theory of evolution. In his "Tag- und Jahreshften" of 1791 he finds the following: "I was fully convinced of a general type running through the entire organic creation through metamorphosis, which may be observed in all of its parts and in a certain degree throughout all nature." At about the beginning of 1805 Goethe suffered from the severest illness of his later years, an attack of renal colic, and for several days it was doubtful what the outcome would be. Eighteen years later he had an attack of pericarditis. In the winter of 1831-32 he contracted a severe cold about the middle of March, and this led to catarrhal fever; he complained of cough, pain in the chest, loss of appetite, and general malaise. For a few days his condition improved, but in the night of March 19 and 20 he had a heavy chill followed by a great difficulty in breathing; his condition gradually became worse and death resulted March 22, at about 12 o'clock. About two hours previously he spoke those now famous words, "more light" ("Macht doch den Fensterladen im Schlafgemach auf, damit mehr Licht hereinkomme"). In his early years he lived a somewhat careless life and drank considerable quantities of beer, wine, and other spirituous drinks, but during his later years he is said to have led a very temperate life. In personal appearance, we are told, that the poet is flattered by portraits of Kaulbach, Jaeger, and others; his face was not regular, his body not normally proportioned; the left side of his face was longer than the right, the right eye was deeper, the nose was prominent, the mouth full and

sensitive, the lines of the chin were strong; he was not much above middle size and was of the South German brunet type with a somewhat pale face.

Aside from the influence which his medical associations and studies had upon his discoveries in anatomy and natural history we cannot doubt that they did much more for Goethe. No profession comes in such intimate contact with the real lives of men, and no doubt much of the insight which he gained into human nature came through his early medical associations. The medical profession is justly proud of the famous names that it has furnished to literature, but there are no doubt many other eminent writers, who like Goethe, were strongly influenced at some period by contact with medicine and medical men.

Cleaning fingernails with the teeth is one of the filthy habits which in some communities is considered proper form. Physicians and dentists do not even seem to be excepted. A certain physician recently lost the clientage of a wealthy family because he was observed chewing his fingernails. Among all people the physician should be a model for cleanliness, both as to his person and habits. Carelessness of personal habits will in time beget carelessness in other important matters.

Perforation in Typhoid Fever Operation.—G. G. Davis (*University Medical Magazine*, May, 1900) reports 3 cases of perforation in typhoid fever and gives the result of operation in each. The first patient was a man 33 years old, who had suffered from enteric fever some 3 weeks. Suddenly symptoms of perforation appeared and an operation was performed. Evidences of mild peritonitis were found: there was an excess of abdominal fluid, and the intestines were highly injected. No perforation was found. The abdomen was thoroughly flushed out and closed without drainage. All symptoms of perforation disappeared and the patient recovered. In the second case, a man, 26 years old, who had been treated for typhoid fever for 7 weeks, was taken with sudden pain in the right iliac fossa, tympanites and other symptoms of perforation. The abdomen was opened and free pus found in the abdominal cavity, a small perforation was found 10 cm. from the ileocecal valve. The perforation was closed, the abdomen irrigated, and drainage inserted. The patient recovered. In the third case, a woman, 29 years old, had symptoms of perforation after suffering from typhoid fever for 3 weeks. On operation the appendix was found perforated. It was ligated and removed, another perforation was found more than a foot above the ileocecal valve. The abdomen was treated in the usual way but the patient died. [M. B. T.]

Gangrenous Umbilical Hernia: Enterorrhaphy.—George Wilkinson (*The Quarterly Medical Journal*, Feb., 1900) reports a case of strangulated, gangrenous umbilical hernia in a fleshy woman, 49 years old. The hernia had persisted for 26 years and during the past 10 years had been irreducible. It became gangrenous and an operation was performed. A loop of the transverse colon, 12 inches long, was involved in the gangrenous process. The whole was removed and large sized Paul's tubes were tied into the open ends of the colon, and brought out the wound, forming an artificial anus. Six weeks later a second operation was performed. The two ends of the divided colon were brought together with a large Murphy button. Three weeks later the button was passed. The patient made a somewhat slow but good recovery. [M. B. T.]

Correspondence.

THE STOMACH CONDITIONS IN INTESTINAL INDIGESTION.

By BOARDMAN REED, M.D.,
of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE very able and scholarly paper by Dr. Porter, the publication of which was concluded in the *JOURNAL* of May 26, calls for a few words of comment. All must concede the profound and accurate acquaintance with the physiologic chemistry of the digestive processes which it shows, and a full meed of praise should be given Dr. Porter for such a lucid exposition of a most important subject.

I trust, however, that neither Dr. Porter nor others will consider me hypercritical when I call attention to one or two points on which the paper is liable to mislead practitioners who have not carefully investigated these digestive problems for themselves. These points are not only highly important from the practical side, but illustrate strongly the impossibility of considering satisfactorily intestinal digestion apart from a precise study of the gastric functions both secretory and motor.

There are various possible causes of intestinal indigestion, and Dr. Porter has done a real service in emphasizing the great frequency with which it results from eating the wrong food, as well as from eating excessive quantities of even proper kinds of food, relative to the amount of exercise taken, i. e., an alimentation out of proportion to the oxygenation. And it is also true that in a large proportion of these cases, the primary injury is to the cells of the liver and intestinal glands. But very certain it is, that in nearly all, if not all, cases, the stomach is either primarily or secondarily involved, and that when it is, we cannot safely afford to ignore it.

In a majority of cases* of gastric indigestion, whether primary or secondary to the intestinal form, there is at first an excess of hydrochloric acid secreted. My own observations prove this fact beyond question, and any clinician who ignores it, will meet with many failures.

Dr. Porter in discussing treatment advises the prescription of hydrochloric acid in intestinal indigestion without any previous examination to determine whether or not its secretion is deficient. In hyperchlorhydria, the most frequent form of gastric indigestion, it would be manifestly useless and, in fact, decidedly injurious to put into the stomach more of a substance already present in excess. Indeed, the first effect of overeating and too rapid eating is often to increase largely the secretion of HCl and other elements of the gastric juice, nature trying in this way to meet the excessive demands made upon her, and the hyperacid chyme passing into the duodenum is one of the most potent and frequent causes of intestinal derangement.

Another active cause of the latter is stagnation and fermentation of the stomach-contents in consequence of deficient motor power in the gastric muscular apparatus—a condition which often goes on to atonic dilation. One who has frequently seen the exceedingly sour and often foul-smelling mixture washed out of an atonic stomach 5 to 6 hours after a meal, can easily understand how disease must inevitably result from such foul stuff passing into the intestines.

Not only the wrong medicines, but the wrong diet must

often be prescribed unless we know the functional condition of the stomach; for all the acids, condiments, and according to many good authorities, even meat, increase the excessive secretion of HCl when once hyperchlorhydria has been set up.

CONVALESCENT HOMES.

By ALFRED JAMES OSTHEIMER, JR., M.D.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

MY own experience in enjoying the benefits of a convalescent home for scarlet fever prompts me to believe that a description of the place and an exposition of its purposes may not only be of interest to other members of the profession, but may also have some weight in instigating a movement for the formation of such homes in the United States. So far as I know, the only home exclusively for convalescents from scarlet fever is the one I am about to describe; *i. e.*, the Mary Wardell Convalescent Home for Scarlet Fever, founded by Miss Mary Wardell in 1884. It is situated on the top of Brockley Hill, near Stanmore, Middlesex, England, about 450 feet above the sea level, on a gravelly soil, with a substratum of clay, with a good southern and western aspect, and is about ten miles northwest of the Marble Arch, London. There are four acres of ground, part of which serves as a pleasure ground for the convalescents (and includes lawn tennis and croquet grounds), the remainder being laid out as kitchen garden, orchard, etc., forming an outer belt to which patients are not admitted, so that they cannot approach the boundary fence.

The house itself consists of a dining-room and drawing-room, each with a southern aspect, for the use of convalescents paying for first-class accommodations; a large day-room looking southwest and north, for the ordinary class-patients; a matron's office and library, with the usual servants' office on the ground floor, beneath which is a well-lighted and ventilated basement, in which are the furnaces for heating the warming apparatus and the hot-water supply to the bathrooms, etc., so that the sitting-rooms are thoroughly protected from damp.

On the first floor are the bedrooms and bathrooms for first-class patients, the matron's bedroom, and the linen-room, while the top floor contains the dormitories and bath-room for the second-class patients, as well as the dispensary and nurses' room.

The annex, containing closets, slop sink and lift, is built apart from the house, with glazed brick walls and tiled floors, and communicates with the house on each floor by means of a short passage, shut off at either end by a swing door. A private omnibus belonging to the home fetches the patients from the hospitals or their own houses. This ambulance can also be sent by rail for patients from a distance. The house is planned for the reception of about 40 patients. A complete disinfecting apparatus is situated in a building especially erected.

The home is intended for the reception of persons recovering from scarlet fever, who have arrived at the stage of the illness when removal from the confinement of one room (where the acute stage has been passed) to fresh air and outdoor life, under careful supervision, is most beneficial. This change, under ordinary circumstances, cannot be effected without danger to others, until many weeks have passed.

Though originally intended for the benefit of the working classes, the founder was led, at the earnest request of the then leading members of the medical profession of London,

to provide accommodations also for persons of a class able to pay the cost of their maintenance. The total number of patients admitted since the home was opened in 1884 is 3,274.

The institution is supported by public subscription and patients' payment. Each patient costs the home about £3 a week. The first-class patients pay from 3 to 5 guineas a week, while the second-class convalescents contribute from 10 to 15 shillings weekly.

Self-interest alone should dictate the establishment and support of such homes to all who dread the disease for themselves or families. The common mode of expressing these fears has no practical result further than to increase the danger by the inducement to deception and concealment it offers to those who are suffering from a misfortune caused by no fault of their own, and to whom candor brings no aid, but only entails ruin.

Convalescent homes, such as have been described, would relieve the fever hospitals at times of epidemics, and would afford means of passing the tedious time of convalescence and desquamation in a healthful environment, as well as in the company of one's fellow creatures.¹

It follows, therefore, that nowadays, in every large community, on account of the ubiquity of scarlet fever, convalescent homes for scarlet fever are not a luxury, but an absolute necessity.

THE INCREASE OF GENERAL INFORMATION BY TRAVEL, ETC.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

WE all agree as to the advantage arising from the periodic assemblies of medical men, especially such as lately graced the National Capital. If these gatherings in Washington have been productive of no other good, they at least act as object-lessons to our visiting brethren, many of whom, pardon the remark, are sadly deficient in general information.

Among many little incidents of the kind may be cited that of a professor in a leading medical school in one of our large commercial centers, who did not know that the National Almanac is prepared in Washington; that the time of the 75th meridian is calculated from here; that the time ball in New York is dropped daily by electric contact with our Naval Observatory; that ships' chronometers are rated in Washington, etc., etc.—in fact he did not know that there was such a thing as the Naval Observatory.

Another, who has for several years had charge of a large clinic, thought all our big guns were made by *Carnegie*; consequently the Washington gunyard with its splendid plant and over 2,000 workmen was a revelation to him. Like many others this man did not know the difference between the navy and the revenue marine, and all attempts to explain the respective distinctness of the Marine Corps and the Marine Hospital service were simply hopeless. When it came to explaining the respective functions of the legislative, executive, and judicial branches of the government things were still more at sea.

A specialist at one of the large metropolitan medical schools was ignorant of the fact that the largest hospital for the Insane is at Washington, in fact did not know that there was one here, and made quite a disparaging remark as to

¹ *British Medical Journal*, August 30, 1879. *British Medical Journal*, March 18, 1882.

the unappreciativeness of our local physicians, when examining some specimens of prehistoric trephining; yet he did not know that one of the persons addressed had written exhaustively on that subject as well as on cephalometry and craniometry and had perhaps handled more skulls than any man in the United States.

We are accused of being dull and provincial in our parliamentary city, and I dare say we are, when judged by commercial standards. On the other hand, to a person in the habit of visiting the clubs of New York for instance, one of the most apparent things is the paucity of conversational topics, which seldom go beyond stocks, Wall Street, and the latest erotic play at the theaters. However enlivening a little of this may be, life at the great Yankee capital is broader, notwithstanding its reputation for intrigue and empty talk, and with the possible exception of Rome no other city offers to the observant and receptive visitor so many object-lessons.

M.D.

Washington, May 30.

Removal of Both Uterine Appendages During Pregnancy.—J. Wesley Bovée (*Virginia Medical Semi-monthly*, May 11, 1900) details a case of double pyosalpingitis complicating 2 months' pregnancy in which both appendages were removed by the abdominal route and the patient made a good recovery. At the expiration of the 9 months' period she was delivered by forceps, after a tedious labor, of a still-born child. He concludes that the third and fourth months of pregnancy seem to be the most satisfactory period for operation, since after that period the size of the uterus would interfere with the operation. There would seem to be more danger of interruption of pregnancy in removing the appendages for tubal disease than for ovarian conditions, since in the latter the pedicle may be left longer and the ligature placed further from the uterus. The beginning of the uterine pains should be a positive indication for the free use of morphin. [M.B.T.]

Two Cases of Interscapulothoracic Amputation.—J. William White (*University Medical Magazine*, May, 1900) reviews the history of interscapulothoracic amputation and reports 2 cases. In the first, a man 22 years old, the right shoulder-joint had been enlarged, painful and stiff for some 2 years. The pain was dull and elicited by deep pressure. There was uniform enlargement of the head of the right humerus. The swelling extended deeply above and below the clavicle toward the median line. The condition was believed to be due to a malignant growth, and an interscapulothoracic amputation was performed. On microscopic examination, the capsule was found undergoing osseous changes in certain areas. In other areas the cell arrangement suggested sarcoma, the enlarged lymph-glands showed areas of softening, areas of hemorrhagic infiltration and increase in the glandular elements. There was an infiltration of spindle cells between the muscle fibers. In the second case, a man 34 years old had received a severe shock from a live wire, which deprived him permanently of the use of the arm. The arm was soon after broken, was greatly swollen and became indurated. Several operations were performed on the arm in the attempt to induce union and in removing sequestra. Finally amputation became necessary. Nine months after the electric shock, the ordinary shoulder-joint amputation was done, hemorrhage, however, being very great. Six months later the patient returned to the hospital with a new growth resembling granulation tissue in the cicatrix at the shoulder. This growth on microscopic examination proved to be sarcoma. An interscapulothoracic amputation was done, the operation being remarkable for the great amount of hemorrhage. The patient entirely recovered. In both of these operations the subclavian artery and vein were ligated before proceeding with the operation. White says the mortality for this operation should not be more than 10%, but that the prognosis as to recurrence is very unfavorable, probably not more than 20% remaining permanently cured. [M.B.T.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Dr. Alfred J. Ostheimer, Jr., of Philadelphia, has just received the degrees of M.R.C.S. and L.R.C.P. in London.

Bequest to the College of Physicians.—By the will of the late Dr. John Ashmurst, the College of Physicians of Philadelphia has the privilege of selecting from his medical books a total number not exceeding 1,500 volumes.

A Christian Healer failed to restore the hearing of a patient at Camden, N. J., and is also alleged to have failed to account for \$1,000 which he had been given power of attorney to look after while the patient resorted to prayer. The aid of the court of chancery has been sought to recover the cash.

Dairy and Food Commissioner to Visit Philadelphia.—The expected visit of Commissioner Cope to Philadelphia is to be the signal for a more active campaign against impure foods and the unwholesome condition in numbers of stores in the poor sections of this city. The primary object of the visit is said to be the disposition of the cases against oleo dealers and others who are held for alleged infractions of the pure food law.

Medical Requirements in New Jersey.—The State Board of Medical Examiners met at Newark, N. J., July 5, 1900, and passed resolutions to the effect that licenses of any State Board of Medical Examiners in the United States will be indorsed in lieu of an examination, provided that the candidate shall present satisfactory evidence of having the academic and medical education required by this Board, and that the license shall have been issued after a State examination of the same grade and kind as that required by the Board.

Dealer in Impure Butter Held.—Charged with selling renovated or process butter without marking it as such in compliance with the law, Seltzer & Hinchman, of Ambler, Pa., were held in \$300 bail for court, July 17. The defendant firm claims to have been imposed upon by a wholesale firm in Philadelphia which sold the renovated butter for pure butter. It was decided that the best course to pursue was to return the case to court, where it can be dropped if the county authorities see fit, in case the firm supplies legal information against the Philadelphia wholesaler who sold the product.

Alleged Leper Wanders Abroad.—Sam Lee, the Olyphant Chinaman believed to be suffering from leprosy, has been the object of the closest attention on the part of medical men, while the vicinity of his laundry is shunned by every one. A special meeting of the Olyphant Board of Health was held July 17, and the State Board of Health has been notified. Later the Olyphant authorities relaxed their vigilance and he left for parts unknown. The Board of Health has been severely censured. The alleged leper was found in Boston, Mass., on the 24th, and was examined by the medical staff of the Board of Health, but was found not to be afflicted with leprosy. The house was under police surveillance as soon as it became known, but the street was filled with Chinamen and many citizens living in the district, who were filled with dismay at the rumor of an alleged leper about to make Chinatown his abode.

Philadelphia Charities.—At a recent meeting of the Board of Charities and Correction the reports of the outdoor physicians, 50 in number, for the month of June, showed that during that period there were 4,344 visits paid to 1,504 patients and 4,459 prescriptions were compounded. The Committee on Charities reported that the inmates of the Almshouse and Hospital at the present time number 3,684, including 1,104 in the outwards, 1,409 in the insane department, 963 in the hospital, and 208 children. Upon the recommendation of the committee a resolution was adopted that certain inmates who are constantly being recommitted to the hospital, being addicted to the use of liquor, and are on

the verge of delirium tremens, receive medical treatment, and when improved be committed in due legal form to the House of Correction, where they must work or be punished. Dr. M. B. Hartzel and Dr. E. S. Gans were elected dermatologists to the institution.

Physician Held for Not Reporting Case.—Dr. O'Reilly, of Philadelphia, was arraigned before Magistrate Eisenbrown, July 23, charged with failing to report a case of diphtheria to the Board of Health. Theodore M. Hudson believes his child would not have contracted the disease had he known there was a case of diphtheria next door, and holds Dr. O'Reilly responsible for the death. Dr. O'Reilly testified that he had not reported the case next door because it was follicular tonsillitis. The court sustained Dr. O'Reilly, discharging the case.

Vital Statistics of Philadelphia for the week ended July 21, 1900:

Disease.	Cases.	Deaths.
Total mortality	564	
Cholera infantum 89, cholera morbus 2 . .		91
Inanition 23, marasmus 34		57
Tuberculosis of lungs		45
Inflammation of stomach and bowels . .		42
Apoplexy 13, paralysis 17		30
Convulsions		30
Heart disease		27
Carcinoma		17
Sunstroke		17
Old age		12
Diphtheria	42	9
Congestion of brain		8
Uremia		8
Measles		6
Typhoid fever	40	5
Scarlet fever	46	3

NEW YORK.

Bushwick Central Hospital.—Dr. H. W. Lincoln has been appointed gastrologist.

An Epidemic of Diphtheria in Brooklyn recently is said to be caused by refuse matter used to grade some streets.

Tuberculosis to be Reported.—Physicians of Montclair, N. J., have decided to report all cases of tuberculosis that come to their attention to the Board of Health.

Rabies Fatal Three Months after Bite.—Dr. James Haley, a veterinary surgeon, died in Bellevue Hospital, New York, July 23, from hydrophobia, the result of a dog's bite received last May.

Fortune Left to Christian Scientists.—An estate valued at \$70,000 has been left to the Christian Scientists of Rome, N. Y., by Mr. and Mrs. M. M. Davis, to erect a Christian Science Temple at that place.

Symptoms of Yellow Fever at Hoffman Island.—A Syrian woman, one of the passengers of the steamer *Havana*, who was detained on Hoffman Island, died suddenly on July 18, and the autopsy shows some indications that she died of yellow fever.

Milk Famine Threatened in New York.—On account of the hot weather, there is a decreased supply and an increased demand for milk in New York, which threatens to develop into a famine. The price has been advanced, and if the present hot weather continues the poor will feel sharply pinched.

St. John's Floating Hospital.—The twenty-fifth anniversary of the beginning of the floating hospital service of St. John's Guild was celebrated, June 19, by appropriate exercises on board the *Emma Abbott*, which was the first boat fitted up by the guild. Since 1875 she has carried 826,312 mothers, sick babies, and delicate children.

Fresh Air for the Poor.—Over 500 women, children, and babies have already been kept for a stay of 2 weeks at Sea Breeze, the summer home at Coney Island of the New York Association for Improving the Condition of the Poor. There are hundreds on the list awaiting their turn. There have been 15-day excursions, on which 5,000 have been taken from the city for a day's outing.

Car Cleaning a Menace to Health.—At a meeting of the Central Labor Union of New York, July 22, it was decided to send a complaint to the Board of Health against the Manhattan Elevated Railroad Company because the cars of this company are cleaned at night when people living near the track are obliged to close all windows on account of the dust.

Buffalo Academy of Medicine for the session of 1900-1901. The chairmen of the different sections are as follows: Of Medicine, Eli H. Long; Surgery, Marshall Clinton; Obstetrics, Albert J. Colston; Pathology, Eugene A. Smith; Ophthalmology, O. Ology, etc., F. W. Hinkel. A prize of \$50 is offered by Dr. Marcel Hartwig, president of the Academy, for the best paper presented to the Academy, by a Fellow thereof, during the session.

Prayer Failed to Cure Lockjaw.—Because of her faith in her prayers and her certainty that they would be answered, Mrs. Annie Tunstead, of East Orange, N. J., did not call for the services of a physician for her son and the lad is now in a most critical condition from lockjaw. He shot himself through the forefinger of his left hand on July 4. Recently he became worse and he suffered a great deal. The mother then sent for Dr. William B. Graves, who, as soon as he came, detected the symptoms of tetanus. The hospital authorities do not entirely despair of saving him.

Effects of Milk Inspection.—As an example of the work of the New York Board of Health the Borough of Manhattan is divided into 9 milk inspection districts. There are 10 milk inspectors, and each district comprises about 600 or 700 milk stores. In 1899 these inspectors made 8,047 inspections, examined 48,832 specimens of milk, and caused 117 arrests. As an example of the effects of this vigilance, it may be noted that only 84 quarts of milk were destroyed in the year 1899, although 10,000,000 pounds of foodstuffs were condemned in that year by the Health Department. Since 1896 every milk dealer has been required to obtain a permit from the Health Department, which is issued only after satisfactory inspection of the place from which the milk is to be sold. If a dealer has been arrested and convicted twice for selling milk below the required standard, this permit is revoked and the dealer is no longer allowed to continue in business. As a result of this oversight there has been a vast improvement in the milk-supply of New York, although much remains to be improved in the matter of cleanliness. Dr. Betz, of the Health Department, has estimated the comparative amount per capita of milk consumed in the following cities:

London.....	4 ounces ($\frac{1}{2}$ pint)
Paris.....	7 $\frac{1}{2}$ ounces ($\frac{1}{2}$ pint)
Munich.....	20 ounces (1 $\frac{1}{2}$ pints)
New York.....	18 ounces (1 $\frac{1}{2}$ pints)

NEW ENGLAND.

Death Due to Glanders.—Lyman C. Albee, of Fitchburg, Mass., died July 22, from glanders which he contracted while caring for a horse. He had been ill about 8 days. His son now has the same disease.

Disease from Refuse Used on Farms.—More malaria and fevers exist in the 2 wards of New Haven adjoining Hamden than in the other 13 combined. The cause is believed to be the garbage and refuse matter from the city which is used as fertilizer on the truck farms of Hamden. The Board of Health has been notified.

Measles on the "Newport."—The naval training ship *Newport* returned to Newport from Boston July 23 with several suspicious cases of measles on board. During a recent visit of the *Newport* here an epidemic of measles developed, and the sick cadets at the time were sent to the Naval Hospital, on Coasters Island. All recovered, and the ship sailed with the belief that the sickness had entirely disappeared.

Tuberculosis in New England.—The mortality from tuberculosis in New England is steadily decreasing. The latest report of the State Registrar of Vital Statistics for Maine demonstrates that such a diminution has been in pro-

gress for a number of years. In 1892 there were 1,352 deaths, and in succeeding years 1,299, 1,262, 1,195, 1,172, 1,128, and 1,021. The State Board of Health issued its circular on the prevention of tuberculosis 11 years ago, and since then it has repeatedly been published in large editions which have been distributed in every town.

French Canadian Fecundity.—A French Canadian living in a Rhode Island town was recently presented by his third wife with his forty-first child. His first wife gave birth to several pairs of twins, and his second presented him with three sets of triplets. Of the children 36 are living, and many have families of their own. Of the grandchildren 8 are also parents. This patriarch, according to the *British Medical Journal*, may be congratulated on a "fecundity" which should satisfy even the large ideas of M. Zola on the subject. The case here quoted, though remarkable, is by no means a unique instance of the fidelity with which the French Canadians carry out the precept "Increase and multiply," which is so generally neglected by their cousins in the mother country.

CHICAGO AND WESTERN STATES.

Fresh Air for City Waifs.—The Bureau of Charities of Chicago has been giving each week a 2 weeks' outing to about 400 children under 15 years of age.

Smallpox in Wisconsin.—A case of smallpox has developed in a lumber camp at Wentworth, Wis., and the entire camp has been quarantined.

The Cincinnati Academy of Medicine is to receive, by the will of the late Dr. Charles P. Judkins, at the death of his widow, two-fifths of an estate valued at \$100,000.

Pure Water for St. Louis.—The Meramec Springs, at the base of the Ozark mountains, about 70 miles from St. Louis, are to be tapped and their water piped to the city. The cost will probably be \$30,000,000.

Fatal Headache Powders.—Benjamin V. Beckes died July 19 from effects of an overdose of headache powders, at his home east of Vincennes, Ind. He was 53, a wealthy farmer and belonged to an old aristocratic family.

Chicago Hospitals Get Legacies.—By the will of the late T. B. Blackstone the following hospitals received legacies: Passavant Hospital \$25,000; Relief and Aid Association \$25,000, Chicago Orphan Asylum \$25,000; St. Luke's Hospital \$25,000.

Fined for Using Milk Preservative.—The Health Department in Chicago has been sustained in a test case charging a milk dealer with the use of formalin as a milk preservative. He was fined \$20 and costs for violating the city ordinance, which prevents the use of any preservative.

Defective Eyes in Chicago.—Naval officials, especially of the marine branch of the service, believe that people of Chicago are subject to eye troubles more than those of any other city in this country. The statistics of the marine recruiting officer show that nearly 50% of the rejections have been on account of defective vision.

Mob Would Lynch Divine Healer.—On July 21, at Mansfield, O., a mob attacked Cyrus B. Flockler, a divine healer, and had it not been for the police force, would have tarred and feathered or lynched him. Flockler gathered a flock at Mansfield and, by his refusing to have physicians called, several infants died under his faith-cure treatment, and several of his "Zionist" followers were driven insane.

Dr. Senn Offers Services in China.—Dr. Nicholas Senn, of Rush College, Chicago, chief of the operating staff of the army in the field during the Cuban campaign, has offered his services to the United States Government as surgeon in China. "The United States will not be caught napping again in the hospital service," he said. "The lessons learned in the Cuban War will stand the nation in good stead now."

Typhoid Fever Rages in Golf Club.—The Midlothian Country Club, of Chicago, is stricken with typhoid fever; 47 members and employees are ill and 2 have died. Poor water

is the cause given for the outbreak of the malady. The club's supply is obtained from 2 deep wells. During the recent hot spell the golfers and attendants drank freely, and soon cases of the fever became prevalent. A bacteriologist found typhoid germs in the water.

Decreased Mortality in Chicago.—A reduction of 47% in the death-rates of Chicago for the week ended July 14 compared with the same week of July, 1899, is attributed to a more general observance of the health directions given out by the Health Department and to the improved sanitary quality of the water-supply as shown by the wonderful decrease in the number of deaths from the impure water diseases—80 last week as against 182 last year.

Illinois Pharmaceutical Association.—Methods for preventing competitors from selling patent medicines at cut rates were discussed at the meeting of the Illinois Pharmaceutical Association, June 18. A member of the executive committee of the national association said that an agreement had been signed which aims to increase the druggist's profit on patent medicines, and at the same time drive the cut-rate dealer out of business. The druggists were so enthusiastic over the work of the association and the prospective raise in prices that nearly \$1,150 was raised by subscription to push the work. Resolutions were adopted to be presented to President McKinley and Secretary Gage, requesting that the pay of United States hospital stewards be raised to \$1,200 per year, and that they have all the perquisites and privileges of surgeons in government employ. The Louisiana Association has already presented these resolutions.

SOUTHERN STATES.

W. S. Halsted, F.R.C.S.—During the recent centennial exercises of the Royal College of Surgeons, England, Professor W. S. Halsted, of Johns Hopkins University, was made a fellow.

Smallpox in Texas.—At Jefferson, Texas, 12 new cases of smallpox have been officially reported. There have been many exposures and an epidemic seems almost certain. Thus far the disease is in a mild form.

Correction.—The news note in our issue of June 21, to the effect that Dr. W. H. Welch had been appointed professor of therapeutics and materia medica at Johns Hopkins University, is incorrect. We trust that Professor Welch will long retain his position as professor of pathology.

New Orleans Water-Supply.—At a meeting of the Sewerage and Water Board of New Orleans, on July 19, the water-supply of the city was discussed. Exhaustive experiments will be carried out as to purification and sources of supply. Superintendent Earl submitted a report as to the purification methods in other cities.

Memorial to Dr. Rohe.—The memorial tablet to be placed in the rooms of the Medical and Chirurgical Faculty, Baltimore, in honor of the late Dr. George H. Rohe will be completed in time to be unveiled at the November meeting of the Maryland Public Health Association. In addition to the bronze portrait tablet the committee hopes to establish in the same room with the tablet what will be known as the "Rohe Collection of Books." Already on hand is a nucleus of books in the shape of German and French monographs, which belonged originally to Dr. Rohe.

The Orleans Parish Medical Society.—On July 14, 1900, Dr. S. P. DELAUP read a paper on the *anatomy of the kidney*, and Dr. HERMANN B. GESSNER on the *physiology of the kidney*. Dr. Gessner exhibited a patient from whom he had excised the left half of the lower maxilla, for osteosarcoma. The operation had been followed by splendid results; there being present comparatively little deformity. The patient is apparently cured of his original affection. The States of Louisiana and Texas have, through their respective Boards of Health, signed agreements whereby most articles of freight will be permitted to pass the quarantine lines, in the event of the occurrence of fever in either State this season. These agreements will greatly lessen the usual embargo placed upon commerce by recent outbreaks of fever.

CANADA.

Ontario Association for the Prevention of Tuberculosis.—The interest of medical men in problems of hygiene, especially those connected with the spread of contagious disease, is manifested by the formation in Ontario of an association for the prevention of tuberculosis. Dr. James Thorburn is president of the association. By recent provincial legislation local municipalities have power to establish sanatoria directly under the control of the Government, and it is the object of this association to stir up a general interest in limiting the spread of this disease, and the ultimate establishment of as many properly endowed sanatoria for the care of consumptives as possible.

MISCELLANY.

Dr. Thomas M. Lippitt, the surgeon in charge of the marines sent as a legation guard to Peking, and who is supposed to have been massacred, was an assistant surgeon in the Army. He was born in Berryville, Va., in 1873, was graduated from Starling Medical College in 1897 and was commissioned assistant surgeon in the Navy June 27, 1898.

Cure For Yellow Fever.—The first patient treated with the yellow fever serum at Vera Cruz by the young Brazilian experimenter, Dr. Bellinzaghi, is reported fully convalescent. Other patients treated are said to be progressing favorably. There is intense interest in the experiments. Patients very low with black vomit have been treated, and the effect of the serum is marvelous.

Surgeons Ordered to China.—The following assistant surgeons have been ordered to San Francisco for duty in China: S. M. DeLoffre, Omaha, Neb.; W. E. Chapman, Sheboygan, Mich.; H. C. Many, Honesdale, Pa.; R. W. Newton, Barre, Vt.; W. W. Reno, Detroit, Mich.; M. J. Rowe, Bridgeport, Conn.; L. A. Spaeth, Jersey City, N. J.; L. A. B. Street, Brookline, Mass.; I. M. Unger, New York; E. E. Lamkin, St. Louis.

"Medical Ethics Killed Two" was the subject of a paragraph in a daily journal. It seems that a family physician complained to his patient because the latter called another physician without consulting him. The son of the patient took up the grievance and doctor and son stepped outside the house and drew their pistols. The result was that both were killed. The patient was then at liberty to call in any doctor he chose.

Obituary.—THOMAS STORY KIRKBRIDE, JR., of Philadelphia, July 19, aged 31.—JAMES S. GILLESPIE, of Philadelphia, July 19.—JOHN B. CHAMBERLAIN, of Moss Point, Miss., July 13, aged 36.—SAMUEL RUSSELL WELLS, of Waterloo, N. Y., July 13, aged 76.—ELLIS S. PEABODY, of Taylorville, Ills., July 20, aged 87.—F. A. BLACKMER, of Albert Lea, Minn.—A. BUSKIRK, of Madison, W. Va., July 21, aged 50.—OSWELL B. FINNLY, of Onancock, Va., July 23.

Female Nurses on the Transports.—The *Grant* and the *Sumner*, which are now on the way to China, are carrying 25 trained female nurses, a part of the 30 recently requested for service in the reserve hospitals in the Philippines. Both of these vessels will touch at Nagasaki, and it is possible some or all of these nurses will be diverted for the benefit of the Chinese expeditionary force. It is hardly thought that any of the female nurses will be ordered to shore duty in China, certainly not further inland than Taku. But it is quite possible that if a base hospital is established at Nagasaki some of them will be detailed to duty there.

Pure Water for Troops.—A requisition for over \$14,000 for apparatus to supply the troops of the Chinese expedition pure drinking water has been made. The department already has placed orders for sterilizers and distilling plants which will furnish 82,500 gallons of pure water a day. These will be used inland, where foul water and suspicious well water is encountered. The distilling plants will furnish 7,400 gallons a day and can be used if needed on the sea coast, where salt water will be rendered fit for drinking. This is the most expensive water-purifying plant the United States ever has attempted to send with an army in the field. It is thought that with the addition of boiling water on the port-

able cooking ranges this will furnish an adequate supply for the whole army.

Yellow Fever Among Troops in Cuba.—Yellow fever has broken out in the barracks of the Seventh United States Cavalry and the First United States Infantry in Pinar del Rio, Cuba. There have been 8 deaths during the present month, and 11 cases are now under treatment in the hospitals. Tuesday General Lee ordered the camp moved 3 miles into the country, and quarantine will be strictly enforced. The chief surgeon has received orders to institute a thorough investigation into the cause of the outbreak, and special preparation is being made for a thorough disinfection before the First Infantry embarks for the United States. General Wood says the country districts in Cuba are healthy and the troops have been exceedingly well. There were only a few cases of yellow fever this year, and these were directly traceable to large cities.

Bad Liquor in Manila.—The military authorities at Manila have determined to obliterate the illicit manufacture and sale of bad liquor. A test case has been brought against one firm whose immense stock of this material was seized by order of General MacArthur. The authorities have been impressed with the large number of applications that come in daily, especially from the Chinese requesting license to manufacture wine, whisky, etc. The traffic is not, however, confined to Chinamen. Many Americans and Europeans have gone into the business with every appearance of profit. Army officers at Manila officially express the opinion that the license which has prevailed in regard to sellers of bad liquor is accountable for the disorder which prevails in some quarters. It has excited men to disobedience of orders and insubordination. The latter situation points to the necessity of maintaining Army canteens to be conducted on a strictly military basis.

Smallpox Rages at Nome.—The pesthouse at Nome is full and overflowing with patients afflicted with smallpox and the Government officials are erecting two large structures, one of which, with adjuncts, will cover an acre of ground. The disease has spread rapidly and many cases are quarantined in the tents in which they were discovered. Every Government and city official and doctor in the camp is working night and day with the disease, but it seems useless to try to stop it. Dr. J. J. Tyler reports 200 cases of smallpox in the pesthouse and around the camp, and says the people are being taken down at the rate of 17 to 20 a day. Later reports state that the condition at Cape Nome was exaggerated and that the disease is apparently not spreading. Captain J. C. Cantwell, of the revenue cutter *Nuniak*, which operates in the Yukon River, says in a letter: "The situation as regards disease at Nome is grave, and it is hoped that the true state of affairs will be known in the States in time to prevent more people from crowding into that camp, which is already in a condition of congestion that will have to be seen to be appreciated. The lack of sanitation even in the crudest form has rendered the place a quagmire of disease-breeding filth, and the wild struggle constantly going on for every foot of space renders it impossible to get anything done in the way of cleaning up the town. It will be a merciful Providence if there is not a plague started there before the end of the summer, and if the smallpox cannot be subdued before the cold weather sets in nothing on earth can prevent its spreading to all the adjacent camps."

Medical Missionaries in China.—"The principal reason why the missionaries have been tolerated in China is because of their medical work," said a New Orleans doctor. "That fact is recognized by the church authorities, and for years past the new people sent into the field have nearly all been regular graduates in medicine. All the large Union Mission stations in China have hospitals in connection, and, as they are obliged to put up their own prescriptions, they generally maintain immense pharmacies. It was only 4 or 5 years ago that the sick natives began to trust themselves freely in the hands of the foreign devils, but then they came with a rush, and at present the out-of-door clinic records of the leading mission hospitals are simply astonishing. The number of cases treated runs into the hundreds of thousands, and such establishments are, of course, a tremendous boon to the common people. Their popularity has undoubtedly been a

most important safeguard to the missions proper, for, no matter how bigoted a Chinaman may be, he isn't going to kill off his family physician on account of a difference of opinion in religion. China is a fascinating field for an enthusiastic young doctor, because so many strange and interesting cases are encountered, and some of the missionaries have done very brilliant work, especially in surgery. They are frequent contributors to the leading European medical journals. All nonsense to the contrary notwithstanding, the native Chinese doctors are 'fakirs,' pure and simple. Their remedies are based on childish superstition, and they hold that all febrile disorders originate in a certain artery which they call the 'fever vein.' The treatment is to compress the vein. If the missionaries are driven out, there will be a big jump in mortality in the cities."

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended July 20, 1900:

SMALLPOX—UNITED STATES.

			CASES.	DEATHS.

Changes in the Medical Corps of the U. S. Army
for the week ended July 21, 1900

SHIMER, First Lieutenant IRA A., assistant surgeon, is granted leave for 1 month, from about June 23, with authority to leave the limits of the division of Cuba and apply for an extension of 1 month.

POTTER, Major SAMUEL O. L., surgeon, will proceed to the Presidio for temporary duty.

CLEARY, Lieutenant-Colonel PETER J. A., deputy surgeon-general, is granted leave for 20 days.

FUTCHER, MARION O., acting assistant surgeon, is relieved from duty at Madison barracks and will proceed to Fort Columbus and report to the commanding officer, Third Battalion, Fifteenth Infantry, for duty to accompany that battalion via San Francisco, Cal., to the Philippine Islands.

ALLEN, H. EUGENE, acting assistant surgeon, is relieved from temporary duty at Fort Sam Houston, and will proceed to Fort McPherson, and report not later than July 22 to the commanding officer, Company M, Fifteenth Infantry, for duty to accompany that company via San Francisco, Cal., to the Philippine Islands.

FULLER, First Lieutenant LEIGH A., assistant surgeon, the orders of June 20 which relate to him are amended so as to direct him to proceed to San Francisco, Cal., via Washington, D. C., reporting en route not later than July 19, to the Acting Surgeon-General of the Army for instructions.

POND, ARLINGTON, acting assistant surgeon, will proceed from Rutland, Vt., to Fort Preble for duty to relieve Acting Assistant Surgeon Lewis T. Griffith. Acting Assistant Surgeon Griffith, after being thus relieved, will upon the expiration of his present leave, proceed via San Francisco, Cal., to Manila, P. I., for assignment to duty.

APPLE, W. ELSON, acting assistant surgeon, now at Fort Columbus, will proceed to West Point, N. Y., for duty to accompany Company E, Battalion of Engineers, to San Francisco, Cal., and upon the completion of this duty will return to his proper station.

FOGG, JOHN S., acting assistant surgeon, is relieved from temporary duty at Columbus Barracks, and will proceed to Fort Myer for duty to accompany a squadron of the Third Cavalry to the Philippine Islands, and upon arrival at Manila will report to the commanding general, division of Philippines, for assignment to duty.

BARNEY, CHARLES N., acting assistant surgeon, will proceed from Fort Edward, N. Y., to Fort Monroe for temporary duty.

CORBUSIER, Major WILLIAM H., surgeon, will proceed from San Francisco, Cal., to Washington, D. C., and report to the Acting Surgeon-General of the Army for further instructions.

BORDEN, Captain WILLIAM C., assistant surgeon, is granted leave for 1 month, from about July 25.

DARNALL, First Lieutenant CARL R., assistant surgeon, will report to the commanding officers of the hospital ship "Relief," and the second reserve hospital, Manila, for duty.

DESSEZ, PAUL T., acting assistant surgeon, will report to the commanding officers of the hospital ship "Relief," and the second reserve hospital, Manila, for duty.

MAY, JAMES V., acting assistant surgeon, now in Manila, P. I., is authorized to appear before the examining board for examination for appointment as assistant surgeon, U. S. Army.

SHORTIDGE, EDMUND D., acting assistant surgeon, now in Manila, P. I., is authorized to appear before the examining board for examination for appointment as assistant surgeon, U. S. Army.

SHEPARD, JOHN L., acting assistant surgeon, now in Manila, P. I., is authorized to appear before the examining board for examination for appointment as assistant surgeon, U. S. Army.

DESSEZ, PAUL T., acting assistant surgeon, is authorized to appear before the examining board for examination for appointment as assistant surgeon, U. S. Army.

KNEEDLER, Captain WM. L., assistant surgeon, will report to the chief surgeon of the division of the Philippines, for duty as attending surgeon for the board of commissioners to the Philippine Islands, and such other professional duty as may be required of him.

STUCKEY, HARRISON W., acting assistant surgeon, is relieved from duty at Columbus Barracks, and will proceed at once to Fort Myer for duty to accompany a squadron of the Third Cavalry to the Philippine Islands.

CURRY, JOSEPH J., acting assistant surgeon, now at San Francisco, Cal., will proceed to Washington, D. C., and report to the Surgeon-General of the Army for instructions.

BROWN, WILLIAM E., acting assistant surgeon, will proceed from Taylorville, Ill., to Denver, Col., and report to the commanding general, department of the Colorado, for assignment to duty with troops to be sent from that department to the Philippine Islands.

SMITH, CHARLES F., acting assistant surgeon, will proceed from Whitehall, Mich., to Denver, Col., and report to the commanding general, department of the Colorado, for assignment to duty with troops to be sent from that department to the Philippine Islands.

STOCKLE, CHARLES H., acting assistant surgeon, will proceed from Philadelphia, Pa., to Denver, Col., and report to the commanding general, department of the Colorado, for assignment to duty with troops to be sent from that department to the Philippine Islands.

WALL, FRANCIS M., acting assistant surgeon, will proceed from Warren, Ind., to Denver, Col., and report to the commanding general, department of the Colorado, for assignment to duty with troops to be sent from that department to the Philippine Islands.

NAGLE, JOHN S., acting assistant surgeon, will proceed from Chicago, Ill., to St. Paul, Minn., and report to the commanding general, department of Dakota, for assignment to duty with troops to be sent from that department to the Philippine Islands.

MORE, PAUL F., acting assistant surgeon, will proceed from Chicago, Ill., to Omaha, Neb., and report to the commanding general, department of the Missouri, for assignment to duty with troops to be sent from that department to the Philippine Islands.

FISCHER, CHARLES H., acting assistant surgeon, is granted leave for 1 month, from about August 15.

GORHAM, GEORGE H., hospital steward, Fort Banks, will be sent to Fort Columbus, to report to the commanding officer of the battalion of the Fifteenth Infantry to accompany that company to its destination, for duty.

A board of medical officers, to consist of Major WILLIAM B. DAVIS, surgeon; Major JOHN M. BANISTER, surgeon, and Captain CHARLES M. GASHY, assistant surgeon, is appointed to meet at West Point, N. Y., August 25, for the examination of such can-

didates for admission to the United States Military Academy as may be ordered before it.

The following named officers will report to the commanding generals of the departments indicated below for assignment to duty: Department of Northern Luzon—First Lieutenant GEORGE A. SKINNER, assistant surgeon, and Acting Assistant Surgeons, JAMES V. MAY, EDMUND D. SHORTLIDGE and JOHN L. SHEPARD. Department of Southern Luzon—First Lieutenant BENJAMIN J. EDOAR, Jr., assistant surgeon, and Acting Assistant Surgeons FRANK R. MAUSA and ALBERT L. MILLER. Department of Mindanao and Jolo—Major FREDERICK J. COMBE, surgeon.

The following assignments and change of station and duty of officers are announced: Lieutenant-Colonel CHARLES L. HEIZMAN, deputy surgeon general, will report to the commanding general, department of Northern Luzon, for duty as chief surgeon of that department, relieving Major LOUIS M. MAUS, surgeon. Major MAUS will report to the chief surgeon of the division of the Philippines for duty in his office for the purpose of making such inspections of hospitals and sanitary inspection of troops as may from time to time be ordered from these headquarters. Major EDWIN F. GARDNER, surgeon, will report to the commanding general, department of Northern Luzon, for assignment to duty in that department.

Changes in the U. S. Marine-Hospital Service, for the week ended July 19, 1900:

CARRINGTON, P. M., surgeon, upon expiration of sick leave of absence, to proceed to Point Pleasant, N. J., for special temporary duty.

PERRY, T. B., surgeon, upon return of Surgeon McIntosh from leave of absence, to proceed to Wilmington, N. C., and assume command of the service, relieving Passed Assistant Surgeon C. P. Wertenbaker.

WERTENBAKER, C. P., passed assistant surgeon, to proceed to Washington, D. C., preparatory to receiving orders to assume command of the service at New Orleans, La.

MATHEWSON, H. S., assistant surgeon, to proceed to Philadelphia, Pa., and report to medical officer in command for duty.

WHITE, M. J., assistant surgeon, upon being relieved from duty at Philadelphia, Pa., to proceed to San Francisco, Cal., and report to medical officer in command for duty and assignment to quarters.

HOBBS, W. C., assistant surgeon, bureau order of June 27, 1900, directing Assistant Surgeon Hobbs to proceed to Honolulu, revoked, and directed to proceed to Savannah, Ga., and assume command of the service.

BILLINGS, W. C., assistant surgeon, is granted 15 days' extension of leave of absence from July 15.

ROBINSON, D. E., assistant surgeon, upon being relieved from duty at Memphis, Tenn., to proceed to Seattle, Wash., and assume command of the service, relieving Acting Assistant Surgeon Eagleson.

FOX, CARROLL, assistant surgeon, relieved from duty at Port Townsend Quarantine, and directed to proceed to Dutch Harbor, Alaska, reporting to medical officer in command for duty.

KORN, W. A., assistant surgeon, upon being relieved from duty at Evansville, Ind., to proceed to Philadelphia, Pa., and report to medical officer in command, for duty.

VOGEL, C. W., assistant surgeon, is relieved from duty at San Francisco, Cal., and directed to proceed to San Francisco Quarantine and report to medical officer in command, for duty and assignment to quarters.

LLOYD, B. J., assistant surgeon, is relieved from duty at San Francisco Quarantine, Cal., and directed to proceed to Cape Nome, Alaska, and report to Assistant Surgeon B. H. Earle, for duty.

BURKHALTER, J. T., assistant surgeon, upon being relieved from duty at New York, N. Y., to proceed to Mobile, Ala., and report to medical officer in command, for duty and assignment to quarters.

MCCOY, G. W., assistant surgeon, is relieved from duty at St. Louis, Mo., and directed to proceed to San Francisco, Cal., and report to medical officers in command, for duty and assignment to quarters.

CRAIG, R. C., acting assistant surgeon, is granted leave for 7 days.

GREENSTREET, A. G., acting assistant surgeon, to proceed to Wilmington, N. C., and report to medical officer in command, for duty and assignment to quarters.

Changes in the Medical Corps of the U. S. Navy, for the week ended July 20, 1900:

FITZSIMONS, P., medical director, detached from the naval examining board, Annapolis, Md., and ordered to duty in charge of the naval hospital, Newport, R. I. July 21.

BABIN, H. J., medical director, detached from duty as president of the medical board of examiners, Naval Laboratory, Brooklyn, N. Y., and ordered home and to wait orders. July 25.

HENEGER, L. G., surgeon, detached from the Naval Hospital, Newport, R. I., July 21, and ordered to duty as member of the board of medical examiners, Naval Laboratory, Brooklyn, N. Y. July 25.

MCCORMICK, A. M. D., passed assistant surgeon, detached from the "Chicago," and ordered to the "Montgomery."

WHITING, J. R., assistant surgeon, detached from the "Montgomery," and ordered to the "Chicago."

FISKE, C. N., assistant surgeon, detached from the Navy Yard,

Boston, and ordered to duty with marines at San Francisco, Cal., and then to duty at the Naval Hospital, Mare Island, Cal.

PAYNE, J. H., Jr., assistant surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the Asiatic Station with the fifth battalion of marines.

PROSPER, A., pharmacist, detached from the Naval Academy, July 21, and ordered home and to wait orders; retired from July 3, 1900, under the provisions of section 1143, Revised Statutes, upon his own application after 40 years' service.

foreign News and Notes.

GREAT BRITAIN.

Hospital Ship the Gift of a Maharajah.—In the House of Commons, July 23, the Secretary of State for India announced that the Maharajah of Gwalior had offered the Government a fully-equipped hospital-ship for service in China. It was accepted.

The Housing of the Working Classes Amendment Act.—The bill to amend Part III of the Housing of the Working Classes Act, 1890, as altered by the committee of the House of Commons, has been printed. The Act of 1890 deals in its first part with unhealthy areas—that is, large areas; in its second, with unhealthy dwelling-houses and small areas, including the power of dealing with obstructive buildings; whilst the third part is entitled "Working Class Lodging-Houses." The last-named part, it will be remembered, is adoptive—that is to say, any urban authority in England or Wales, or the city of London, or the London County Council, might adopt this part of the Act, and any rural sanitary authority under certain conditions. The bill as amended enables any council, other than a rural district council, who shall have adopted this part of the Housing Act, to go outside their district, if they deem it desirable, in order to provide such lodging-houses. The bill will enact that the council of any rural authority may, with the consent of the county council, adopt Part III, either for the whole of their district, or for any contrivory place within it. In sanctioning such action the county council must, however, have regard to certain points set forth. In the third clause provision is made for the adoption of the Act by the new metropolitan boroughs and the allocation of their expenses. In the fourth section it is directed that the expenses of the council under Part III of the 1890 Act in rehousing persons displaced under other powers, may be treated as expenses under those powers, but the account must be kept separate. The fifth section enables a nonrural authority outside London, with the consent of the Local Government Board, a London Council with that of a Secretary of State, and a rural district with the sanction of the county council, to lease any land acquired by them for the purposes of Part III; but enacts that certain conditions providing for the legitimate use of such land and buildings for the purposes of the Act shall be inserted, and that the deed of demise shall be endorsed with notice of the subsection. The sixth section deals with the title, and excludes Scotland and Ireland from the provisions of the bill.

CONTINENTAL EUROPE.

Smallpox in Piedmont.—There appears to have been no recrudescence of the outbreak of smallpox with which Italy was threatened last April through the landing at Naples of a number of infected persons belonging to a large party of American tourists, but two cases of hemorrhagic smallpox imported from Toulon and Marseilles are reported at Cuneo in Piedmont. One case has proved fatal and in the other the patient is not expected to recover.

The antimalarial campaign in the Argo Romano has now fairly begun, the 8 ambulances organized for it by the Red Cross Society have left Rome for their various stations. On the first day a large quantity of preventive remedies were distributed and bad cases of malaria sent to the Hospital of Santo Spirito. This crusade will be the means of relieving much suffering and saving many lives. To the same object the experiments which the Society for the Study of Malaria

are again inaugurating in Latium for the malarial season will no doubt contribute. Experiments of similar nature will be prosecuted in Tuscan Maremma and in Salerno and Bari.

MISCELLANY.

The Shah Has Gout.—The Shah of Persia is at present at Contrexeville, where he is under treatment. Drs. Hollander, Dieulafoy and Taccond have ascertained that he had symptoms of gouty diathesis. The Shah is a very punctual patient and follows exactly the orders of his doctors.

Chinese Drugs Become Scarce.—The troubles in China and the consequent falling off of the products of the interior have caused an advance of from 25 to 33½% in the price of drugs shipped from that country, the chief articles of which are cassia barks, oil and buds, oil of aniseed, nutgalls, and Chinese vermillion.

Obituary.—HENRY BURFORD NORMAN, of Chesham, June 11, aged 81.—RICHARD TRUMAN FITZHUGH, of Nottingham, June 15, aged 28.—CORRADO TOMMASI-CRUDELI, of Rome, aged 86.—THOMAS WALLER BARROW, at Woolwich, July 1, aged 83.—JAMES CREAGH, near Kroonstad, July 6.—HENRY EWBANK, of Cheltenham, aged 44.—FRITZ RUBENSTEIN, of Berlin, aged 37.—H. BENEDIKT, of Vienna.—DONALDSON CUMMING, of Aberdeen, at Para, Brazil, June 20.

Modern Famines.—The worst famines of modern times were the famine in Ireland, in 1846-7, in which 1,000,000 people perished; the Indian famine of 1866, which claimed 1,450,000 victims; the Indian famine of 1877, in which 500,000 people perished; and the great famine in China, in 1878, in which 9,500,000 died. The latest reports from India are more favorable. Excellent rains have fallen in many parts and the agricultural prospects in Central India are generally satisfactory.

Cholera in Bombay.—The Governor of Bombay telegraphed to the Secretary of State for India that there were 9,928 cases of cholera in the famine districts during the week ended July 7, of which 6,474 were fatal, and that in the native States there were 9,526 cases, of which 5,892 were fatal. The total number of deaths on the relief works was 5,870. There has been a good rainfall in Surat, Khandeish, and the western part of the Deccan, and rain has begun in parts of North Gujerat, where the numbers demanding relief continue to increase. In Central India there were moderate general rains. The sowing of crops has partly commenced. There has been insufficient rain in the Punjab for dry-land sowing. Notwithstanding the improved prospects no diminution of relief is possible. The condition of the surviving cattle in Western India is deplorable. The health returns from the Central Provinces are satisfactory. The total number of people on relief was 6,148,000.

The Plague.—Only 319 deaths from plague are reported for all India during the week ended June 23. For the previous week 417 were recorded. In the city of Bombay 97 plague deaths occurred, and 32 in the Bombay Presidency exclusive of the city. During the third week of June 1,183 deaths from all causes occurred in Bombay, a high rate when compared with the average for the past five years of 478. Plague is therefore no longer a serious factor in the vital statistics of the city; and the causes are to be found in the destitute state of the people owing to famine in the surrounding districts. Cholera claims a large number of victims. In Calcutta the number of plague deaths during the week ended June 23 numbered 125, and in Bengal, exclusive of the metropolis, 37. During the week ended July 7, 65 fresh cases of plague were notified in Hong Kong, and 68 deaths from the disease. This is a great improvement on the previous week, when the numbers were 99 and 98 respectively. Japan is declared free of the plague at present. In Formosa, however, the disease still lingers. At Smyrna a death from plague occurred on July 4, and 16 cases have been reported up to the present. The total number of plague case in Rio de Janeiro, Brazil, since the commencement of the outbreak until June 29 amounts to 200 cases with 11 deaths. In no outbreak of plague ever recorded has the death-rate been only 5½% of cases attacked, and there is some reason to question whether plague actually exists in South America. Only

7 new cases occurred in Sidney, Australia, during the week ended May 26. The total number of cases since the outbreak is 247, of whom 89 have died. The total number of cases reported in Queensland up to date is 47, of which 16 have died. Of these cases 14 have occurred in Brisbane, 5 of which proved fatal. The latest reports from India indicate a satisfactory decline in the number of deaths from plague. From April 21 to June 16, the number of deaths were respectively in each week: 4,100, 3,365, 2,498, 1,771, 1,214, 975, 746, 503 and 417. In Bombay City the number of deaths from plague during the fortnight ending June 16 was 281. In the Bombay Presidency beyond the city 160 deaths occurred. With all the improvement, however, the mortality from plague alone is twice what it was at this time last year. Plague deaths in Calcutta during the weeks ended June 9 and 16 numbered 122 and 133 respectively. Plague in Calcutta has behaved as though the disease were endemic, while in Bombay epidemics have been the rule. In Hongkong the statistics for the 3 weeks ended June 30 were as follows: Fresh cases, 74, 63 and 99; deaths, 57, 64 and 98 respectively. The Hongkong Chinese thwart the work of the Government in every way. In May the sanitary officials discovered 20 plague cases only by a house-to-house visitation. The crisis in China is bringing an enormous increase of trade to the port and of residents to the town, and the presence of plague in the port is calculated to cause anxiety as to an active spread of the disease. Plague continues to appear in some localities in Japan. The most recent notification of the kind comes from Nakanogo, where, during the third week in May, an alarming outbreak occurred. The number of cases and deaths for all Formosa since the commencement of the year up to May 5 were 379 and 273 respectively. At Smyrna a death from plague was recorded on June 20. The announcement that it had reappeared at Oporto, in Portugal, caused considerable anxiety in Western Europe. The most recent information is, however, that only 1 case of the disease has been met.

Neurotic Muscular Atrophy.—Dercum reports 2 cases (*Journal of Nervous and Neurotic Diseases*, June, 1900), one occurring in a woman, the first symptoms being noted at the age of 42, and involving the feet and legs, later the hands. There was considerable pain along the course of the nerve-trunks, and at the end of 5 years decided loss of sensation. The other case occurred in a man, 57 years of age, who had had pain, commencing in the thighs, for several years. Subsequently, there was wasting of the muscles, loss of power, but no disturbance of sensation. The author gives a brief summary of the findings in those cases that have come to autopsy. [J.S.]

Curettage of the Male Bladder for Chronic Cystitis.—Nathan W. Soble (*Buffalo Medical Journal*, May, 1900) advocates the use of the curet in cases of nontuberculous chronic cystitis that will not yield to ordinary treatment, or even the radical surgical means, such as drainage of the bladder by either the perineal or suprapubic routes. He relates a case in point in which—the ordinary medical means having failed—suprapubic cystotomy was done, followed by irrigation with a silver nitrate solution, all without improvement. One month after operation it was decided to curet the mucous membrane of the bladder through the suprapubic incision for the purpose of removing what seemed to be a thickened, reddened and diseased epithelium, in the hope that a new, healthy layer would be formed. On operation, it was discovered that what seemed at first to be a highly-inflamed epithelial layer was really a plastic deposit, in some portions of the bladder a half inch and more thick, an exudate covering the entire mucous membrane of the bladder, and rendered smooth and glistening by hydrostatic pressure. It required a second curetment to remove all of this tissue. After the completion of the operation the cavity of the bladder was considerably increased and improvement was immediate; the urine became clear almost immediately and in 3 weeks was nearly normal; in 6 weeks the external wound was healed and the patient was walking about, urinating every 2 hours during the day and less often during the night. He has gained 30 pounds in weight. [M.B.T.]

1.—Halliburton gives the result of his experiments on the use of borax and formaldehyd as **preservatives of food**, and takes the ground that the use of foreign substances as preservatives of foodstuffs should be abandoned and if possible be replaced by a more wholesome use of the method of cold transport and storage, for he says: 1. An antiseptic is inimical to the life of the organisms that cause putrefaction; it cannot, therefore, be harmless to the vital processes in the higher animals. 2. Numerous clinical observations have been recorded which show that dyspeptic and other troubles follow the use of foods which have been treated with commonly employed preservatives like borax. 3. Even if, as in the case of boric acid and borax, the poison is not cumulative, the continuous passage of foreign substances through the kidneys cannot be beneficial to those organs. Besides experimenting with borax and boric acid, he gives his results of the influence of formaldehyd on the gastric digestion of proteid, on the pancreatic digestion of proteids, on the pancreatic digestion of starch and the action of formaldehyd on the rennet-curdling of milk. His experiments appear to prove conclusively the injurious effect produced by even minute quantities of certain preservatives on the activity of the enzymes concerned in ordinary digestion and to furnish a cogent reason why the use of these substances should be prohibited for the preservation of food-materials. [A.B.C.]

2.—Berry has written quite an extensive paper on the **removal of goiter** by operation and based on a record of 72 cases, in 33 of which extirpation was practised, and in 39 enucleation, the removal of a tumor or cyst from within the gland, was done. In the majority of these cases the indication for operation consisted in the production of dyspnea caused by the mechanical compression of the trachea by the tumor. In 5 cases only was the operation done because of the deformity present and in 3 patients the gland was removed on account of suspected malignancy. The two forms of goiter which are most dangerous, *per se*, are the rapidly-growing parenchymatous variety occurring at puberty, which in 24 hours are liable to produce extreme if not fatal dyspnea, and the variety in which the growth is situated very low down when a lobule is apt to become displaced and get caught between the sternum and trachea. Unilateral goiters are seldom dangerous even when attaining enormous size. Berry believes that a general anesthetic in cases where there is much dyspnea is fraught with a great deal of danger and in most of these patients it is better to do the operation under morphin, or cocain, or eucain. The incision should be in simple cases transverse in direction and where more room is needed the oblique cut along the sternomastoid is by far the best. In extirpating the gland, all large bloodvessels should be caught and tied before being cut and especial care taken to preserve intact the recurrent laryngeal nerve. In an enucleation the operator should work skillfully and

quickly as the bleeding is apt to be very severe. The results obtained in the 72 cases were very satisfactory, the large majority of the wounds healing by primary union. Of the whole number there were 3 deaths. [G.B.W.]

3.—Barker reports several cases of **epityphlitis** followed by somewhat unusual sequels. The first was one of a subphrenic abscess, which as a sequel of epityphlitis is probably a more common occurrence than is generally supposed. The second was one in which the pus had burrowed up behind the colon and had finally opened into the lungs causing a septic pneumonia. The third case shows the disastrous results of leaving a perityphlitic abscess too long unopened. An artificial anus developed and required the performance of intestinal anastomosis to effect its closure. In the fourth case an intestinal concretion had ulcerated through the appendix and had become imbedded in a mass of adhesions. On separating these adhesions it was found that the concretion had caused the development of an ulcer which opened up the small intestine at a height considerably above the ileocecal valve. In the fifth case the appendix itself without the presence of an irritating concretion had become so inflamed that it had almost ulcerated through into the colon. All of these cases under appropriate operative treatment made good recoveries. [G.B.W.]

4.—Mott says that atrophy of the tangential fibers of the frontal and central convolutions is an early and constant change in dementia paralytica, but it may occur also in alcoholic and epileptic dementia. The **Marchi method** is now adopted by investigators for determining the path, not only of tracts, but of individual fibers in the central nervous system. The chemistry of the Marchi stain does not depend upon the fact that the proteid of the axon has become degenerated into fat, but, as the author has shown, it depends on the differential staining of the phosphoreted fat contained in the myelin (protagon) from ordinary non-phosphoreted fat, such as olein, palmitin, stearin, etc. Not only in **general paralysis**, but in any degenerative process affecting the nervous system if extensive enough choline can be detected in the blood. Mott has discovered that the myelin (protagon) in its degeneration splits up into simpler bodies with the elimination of cholin; this latter escapes into the cerebrospinal fluid and then into the blood where it causes a fall in arterial pressure, partly due to its action on the heart but mainly due to dilation of the peripheral vessels, especially in the intestinal area. Neurine was not found in the blood. In general paralysis a much greater amount of proteid material than normal was found. By examination this was found to contain phosphorus and, therefore, most likely a nucleoproteid. Since a nucleoproteid favors coagulation and stasis, it is probable that this accounts in part at least for the intravenous coagulation and even thrombosis of the lateral sinus sometimes seen in this disease. The Marchi reaction applied to the central and peripheral systems shows there is a rapid disappearance of the products of degeneration in the peripheral nerves as compared with the central nerves. The existence in the former of a chain of tuberculous mesoblastic cells, which compose the sheath of Schwann, probably bears some relation to this difference. There are two forms of **degeneration**: 1. Secondary (Wallerian) degeneration due to interruption of the axon when it is cut off from the cell, and which may be considered of traumatic origin. 2. Primary degeneration, which arises as a result of altered conditions in the blood and lymph, generally by the introduction of some toxic substance. [A.B.C.]

5.—Harrison reports in detail a case of **severe facial erysipelas** in which the temperature had gone to 105. The patient was practically moribund, but began to recover at once on the injection of 20 ccm. of Burrough's and Wellcome's antistreptococcus serum under the skin of the abdomen, repeated twice a day at first by 10 ccm. then once a day. After 2 or 3 days the patient made a complete and rapid recovery. He observed the almost complete absence of sleep, although hypnotics were given at frequent intervals. He is of opinion that the antistreptococcus serum saved the patient's life. [A.B.C.]

6.—Hamilton reports a case of a boy of 12 getting a haricot bean down his trachea. The foreign body at first lodged evidently at the bifurcation of the trachea obstructing the entrance of air to the right lung. Later on the bean became dislodged, causing such dyspnea that it was necessary to per-

form **tracheotomy** to save the boy's life. After quite a large opening had been made into the trachea the bean was forcibly coughed out and the patient made a good recovery. [G.B.W.]

7.—In this case of **separation of one of the costal cartilages** from the sternum the nature of the injury was not recognized until 3 or 4 days after the accident, at which time a distinct click could be felt at the seat of separation. [G.B.W.]

8.—Edington gives a simple method of **fixing blood-films** by making use of a bell-jar which is open at the top. The diameter of it is 135 mm., and the height to the lower border of the neck about 150 mm. The opening at the top is closed by India-rubber cork on the bottom of which is glued an ordinary cover-glass. He uses vapor of formaldehyd. [A.B.C.]

9.—Campbell reports the case of an infant 5 days old, which had blood coming from its mouth, and its stools, which had begun to change, were dark. There was a condition **simulating hemoptysis**, but a repeated close examination showed a very small crack in the mother's nipple, and it was proved that the child swallowed the blood. [A.B.C.]

10.—Mackenzie reports a case of **nasal granuloma** containing giant-cells so that the pathologic diagnosis of tuberculosis was most probable. The growth was very friable and bled freely when touched, and after its removal the hemorrhage was so great that it was necessary to pack the nares. Recurrence has not taken place within six months. [G.B.W.]

1.—See abstracts of *British Medical Journal* for July 7.

3.—Brown reports a case of operation for pyloric stenosis at which he joined a loop of jejunum to the stomach using Senn's plates in the anastomosis. At the end of 2 weeks symptoms of obstruction appeared, the patient soon being as badly off as before operative intervention. Reopening the abdomen he found that, although the **gastrojejunostomy** externally was quite satisfactory, internally the bone plate had disappeared and all trace of the opening was absent. Pressing firmly with the finger along the edge of the former incision he tore through a **membrane** by which the opening had been **occluded**. Following this the patient recovered rapidly. He has no idea as to what caused the formation of the occluding membrane. [M.B.T.]

4.—An appendix was removed from a woman aged 26, March 27, 1900, following the fourth attack of **appendicitis**. The appendix contained a mass a little larger than a marble, appearing like a tuberculous lesion; the patient recovered from the operation, but June 27 she was reported as rapidly losing flesh and strength, with symptoms of

the development of secondary growths in the abdomen. At this time microscopic examination of the vermiform appendix showed most unexpectedly that it was the seat of a spheroidal-celled **carcinoma**. The facts that the growth was most extensive in the mucous coat, that it could be traced outward into the muscular coats, and that there was no growth on the outside of the peritoneum, showed that the growth originated in the mucous membrane of the appendix, and that it was not a secondary growth either implanted on the peritoneum or arising as a result of embolism with its substance. In the few cases reported of **primary malignant disease of the appendix** it is noteworthy that there were practically no clinical symptoms other than those usually in **appendicitis**. [M.B.T.]

5.—Grube states that **hay-fever** or summer catarrh is not confined to the summer months, but is more prevalent then. It may occur at any time of year. He says that most cases are among patients having gout, or of gouty tendency, or with a history of gout in the family. All cases successfully treated were those connected in some way with gout. Consequently treatment should be directed against both the gout and the summer catarrh. Five cases were treated by the author; 4 of the patients were gouty, or had a history of gout in the family; the other was free from this complication. A strict regulation of the diet, and the local application of the Neuenahr waters in the form of inhalations, gargle, and nose-douche effected a cure in the 4 of gouty tendency. The one without this tendency was not cured. Hot baths and massage proved of benefit in those suffering from muscular and articular pains in addition to the catarrh. [A.B.C.]

6.—Smith gives a fully illustrated article considering the effects which may be produced upon a **crooked spine** by specified **muscular exercise**, either by correcting the shape and of strengthening the joints or strengthening any particular set of muscles connected with the deformity. He justly states that it is impossible to lay down unvarying rules for gymnastic exercises by which to deal with every instance of curvature since cases differ to such an extent and that what is suitable to one individual would be totally wrong for another. The article does not lend itself readily to abstracting and those interested would do well to refer to the original. [M.B.T.]

7.—Duncan reports **108 consecutive cases of abdominal section** without the loss of a patient. This includes all his cases of abdominal section from October, 1897, to the present time. There was no selection of cases. The patients were all women and causes for operation included most of those within the field of gynecology. The author discusses at some length his method for preparation of the patient, the operator and his assistants, and the instruments. He also discusses sponges, flushing, drainage, and after-treatment of the patient. Shock and tympanites from intestinal paralysis are the great dangers in abdominal section. The former he combats by hypodermic injections of strychnia; he attempts to prevent tympanites by passing a soft rectal tube up the bowel every 4 hours. If this is not satisfactory an enema consisting of an ounce of oil of turpentine to a pint of warm water is given. [A.B.C.]

8.—Wallace relates a case of **subacute general peritonitis**, probably **tuberculous in origin**, with effusion tending to suppuration, in which laparotomy was recommended. As a preparation for operation the abdomen was thoroughly cleansed and a layer of sterile boric cotton used as a protection over the abdomen and kept in position by a binder; the next day on removing the dressings they were found adherent above the umbilicus, and in the effort to remove them the tissues beneath peeled off and instantly a stream of pus welled up in a jet quite 6 inches high and continued flowing until not less than 24 ounces had escaped; there was immediate improvement and 17 days after the **spontaneous rupture of the abdominal wall** the patient was discharged cured. [M.B.T.]

9.—Sharp's conclusions and deductions are: 1. **Roup, like diphtheria** (including the somewhat indefinite term "croup") varies in its malignancy, sometimes being mild with only one or two deaths in a large hen-run, while the next epidemic may almost clear out the whole coop. 2. The disease does not appear to be transmissible to man, for those handling the affected birds without any precautions do not suffer. 3. Paralysis was, according to my observations, ab-

sent in roup cases. 4. The disease is evidently a highly contagious catarrh and may correspond to the *morve* or fowl glanders of the French. 5. Roup probably differs entirely from "fowl diphtheria," so called. 6. Bird fanciers distinguish between a "dry" roup and a "wet" roup. Dry roup is most likely a simple benign catarrh corresponding to the recurring croup affecting children, especially those inhabiting valleys and near a river bank. Wet roup, on the other hand, in its malignancy resembles diphtheria and membranous croup. 7. The microorganism of the roup (the wet variety) probably lives for a considerable time at least in the earth near the surface and thus it is readily spread from animal to animal. 8. Conditions of soil and surroundings favorable to the spread of diphtheria would likewise appear to favor the spread of roup in fowls. [A B C]

10.—Natives of India are comparatively exempt from hydatid disease, therefore Buchanan records a case which occurred in a native of Bhagalpur who had never left his home. The patient died from a suppurative cyst in the right flank, which did not connect with the peritoneal cavity, and the hydatid cyst was discovered postmortem. [M.B.T.]

11.—MacConkey says in this new medium advantage is taken of two well-known facts: (1) That the salts of bile are precipitated by acids; and (2) that *Bacillus coli communis* produces acid in the presence of lactose, while *Bacillus typhi abdominalis* does not. The composition of the medium is: Sodium glycocholate, 0.5%; peptone, 1.5%; lactose, 0.3 to 0.5%; agar, 1.5%; and tap-water, q. s. The lactose is added after filtration. If stab-cultures be made in this medium with *Bacillus coli communis* and *Bacillus typhi abdominalis*, and incubated at 42° C. for from 24 to 48 hours, it will be found that the tube inoculated with *Bacillus coli communis* has become cloudy, while the tube containing *Bacillus typhi abdominalis* remains quite clear. If glucose be used instead of lactose both tubes become cloudy, but the cloudiness due to *Bacillus coli communis* begins from below and that due to *Bacillus typhi abdominalis* from above. In plates made with the glucose medium, incubated for 48 hours at 42° C. and then left for from 3 to 4 days exposed to the light at room temperature, the colonies gradually become orange-colored. [A B C]

12.—Battle describes a preliminary colotomy for obstruction of the bowels in a man aged 41; relief followed and the patient's condition steadily improved for 3 weeks, when further operation to remove the cause of obstruction was had. Finding a hard mass at the lower part of the sigmoid flexure, with some scattered hard mesenteric glands, about 6 inches of the bowel was removed. On section, it was found that the lumen was almost closed by a columnar-celled carcinoma. The patient looked bronzed and well 11 weeks after operation, having gained 7 pounds in weight; the bowels acted regularly and without difficulty. There was a small sinus at the seat of the former colotomy opening, from which there had been a little discharge. [M.B.T.]

13.—Bell reports that a young man of 24, suffering from gonorrhea, was admitted to the Government Civil Hospital at Hongkong. It soon appeared that the patient was suffering from plague, and examination of the sputum proved this to be true. He had the characteristic symptoms of plague, his temperature running to 106.4°. He was treated early with hypodermic injections of digitalis and strychnin every 4 hours, and 12 grs. of pure carbolic acid in solution were given every 3 hours. The temperature soon commenced to fall, and by the end of the fourth day of this treatment had reached the normal. The man made a good recovery, having taken in all 280 gr. of pure carbolic acid. Bell recommends that this remedy be tried by others. He says it is now being tried on every case admitted to the Plague Hospital, and so soon as 50 cases have been thus treated a report will be made. [A.B.C.]

New York Medical Journal.

July 21, 1900. [Vol. lxxii, No. 3.]

1. The Pituitary Gland as a Factor in Akromegaly and Giantism. WOODS HUTCHINSON.
2. The Prevention of Colds. LORENZO B. LOCKARD.
3. Syphilis of the Brain. J. T. ESKRIDGE.
4. A Brief Consideration of Gangrene and Mortification of the Extremities. THOMAS H. MANLEY.
5. The Etiology and Cure of Hysteria. F. WALTER.

1.—Hutchinson makes the following summary with reference to **giantism**: 1. The greater part of the overgrowth is found at or near the tips of the segment crescents, as in **akromegaly**, differing from the latter mainly in that it is not exclusively confined to the tip of the segment or last division of the limb. 2. The facial part of the skull is enlarged out of all proportion to the cranial, particularly in the region of the lower jaw. 3. The condition, whether it be regarded as normal or morbid, is one that distinctly tends to shortness of life, and would appear to have an average duration of scarcely more than 20 years. 4. The mental and physical vigor of the giant is distinctly below par, and his death usually comes either from a steady progressive increase of this weakness, or from some trifling accident, or usually mild, intercurrent disease. 5. The sexual powers appear in the great majority of cases to be far below normal. 6. There is a decided preponderance of males among the victims of this condition; in all of which statements there is a decided parallelism with akromegaly. Last of all, and from the point of view of this essay of greatest interest, is the fact that the one morbid condition which is peculiar to both these disturbances of nutrition, the enlargement of the pituitary body, is found to be present in a large majority of cases of both. We may conclude, until some evidence to the contrary can be adduced, that akromegaly and giantism are simply different expressions of one and the same morbid condition; in other words, that akromegaly is a general overgrowth tendency which does not, for some reason, begin to express itself until after adult stature has been reached, and which consequently expends itself upon those points in the body at which growth last ceased—the extremities of the segment crescents and the distal extremities of the appendages. Second, that giantism in a large majority of cases is this same condition manifesting itself in childhood or before complete stature has been reached, and the growth in consequence is more symmetrical and less strictly confined to the last segment of the arches and appendages. The author reviews the literature of the subject and says that out of 54 autopsies held in cases of akromegaly and giantism there were only 5 in which the pituitary body was not enlarged. Its hypertrophy in most all cases was very manifest. [A B C.]

2.—Lockard lays great stress on the use of the bath, exercise, and proper clothing to prevent colds, and consequently the graver maladies which arise secondary to them. The care of the child should begin with the proper hygiene of the prospective mother. During the first 12 weeks of life the infant should be bathed daily in water at 95° F.; during the next 12 weeks the temperature should be 93° followed by sponging at 90°; during the last half of the first year the temperature of the daily bath should be 90°; later the temperature is gradually reduced to 85° with sponging at 80°; after the third year the temperature of the water should be 80° followed by sponging at 75°. Any individual younger than 60 years may, by proper exercise, correct dressing, the daily cold bath, and living in the open air and properly ventilated rooms, so "harden" himself as to be almost or quite immune to colds. Even those beyond 60 can do much to prevent colds by carrying out more carefully the plan outlined. [A B C.]

3.—Eskridge quotes Hjelmman as saying that from 1½ to 2% of those contracting syphilis develop syphilis of the brain. Of those having tertiary syphilis the same authority says about 12% have syphilis of the brain. Syphilis of the brain may develop at any time after contracting the disease; there is no time during the subsequent life of the patient when it may not develop. The gumma is the typical specific lesion of the brain. Its formation is always attended by inflammation and tissue formation. It never becomes highly organized, and its tendency is to degenerate, either by caseation or by fibrous degeneration with the formation of cicatricial tissue. If treated before degeneration sets in the gumma can be entirely removed and a cure effected, but if treatment be postponed till degeneration sets in contracting bands of cicatricial tissue will form which cannot be removed by medication because they are nonspecific and secondary to the specific lesion. Gummas are most frequently found at the base of the brain, in the interpeduncular space. The sixth and branches of the third cranial nerves are often affected. On the cortex they occur most frequently in the motor area, and hence lead to impairment of bodily motions. The effect of syphilis on the arteries of the brain is well known, like,

wise its effect on the meninges. The author considers at some length the symptoms of syphilis of the brain. He says obliterating disease of the arteries of the brain before the age of 45, and epilepsy occurring after 30, when not traumatic, may be set down as due to syphilis. He divides treatment into—prevention, general management of the patient, and antisypilitic medication. Under prevention he recommends potassium iodid in 10 to 15 gr. doses thrice daily for 2 or 3 weeks with an interval of probably 4 months. The antisypilitic treatment consists in the use of mercury and potassium iodid. As to which shall be used and how, depends not on the time since the initial lesion, but on the virulence of the process. [A.B.C.]

4.—Manley quotes a number of definitions for **gangrene**, and agrees with that from Boyer, who says: "Gangrene implies the dying state of the tissues; mortification their complete death." The author says gangrene has set in, its destructive work has begun, but the member is not dead, is not mortified; it is in a state of impending death, but is not dead, and in the traumatic type of gangrene of a limb in a healthy subject, by appropriate radical treatment, it should always be saved. He discusses senile gangrene and its treatment. [A.B.C.]

5.—Walter says, if a massive culture of the colon-bacillus, the original colony of which was taken from a noninfectious source, be administered to a case of **hysteria**—that is to say, of the active or convulsive type—latent or posthysterical phenomena, such as paralysis being excluded, the symptoms disappear in from 24 to 48 hours, and the patient is restored to health so far as the hysteria is concerned; debility or neurasthenic phenomena may remain for an indefinite period. The uniformity with which this occurs justifies the placing of this remedy in the class of specifics; indeed, the action of quinin in malarial fever is no surer or more uniform in its results. Two views are advanced to account for this alleged phenomenon: One assumes the existence of a specific organism causative of hysteria not to be differentiated by our present methods from the *Bacillus coli communis*; the other, that in the intestinal tract of predisposed subjects the otherwise harmless colon-bacillus may take on toxic properties. In either event the offending organism is simply displaced by the method of treatment here advocated. [A.B.C.]

Medical Record.

July 21, 1900. [Vol. 58, No. 3.]

1. The Evidences of Prostatic Atrophy after Castration. EDWARD L. KEYS.
2. Neglected Clinical Opportunities in American Medical Centers. S. A. KNOPF.
3. Does "Cross-eye" Affect the General Health? AMBROSE L. RANNEY.
4. Report of a Case of Porro-Cesarean Operation. WILLIAM J. GILLETTE.

1.—Keys, in a lengthy article, condemns castration for **hypertrophy of the prostate**. His conclusions are as follows: 1. Experiments, whether on man or the lower animals, relating to the normal prostate do not of necessity apply to the enlarged prostate. 2. I know of no direct pathologic evidence that castration has ever caused atrophy of a hypertrophied prostate. 3. There is direct pathologic evidence that in a few cases castration has failed to cause atrophy of the hypertrophied prostate. 4. The majority of cases reported thus far have been labeled "cured" or "improved" so soon after operation that many of them are doubtless instances of local depletion. 5. Clinical evidence of this is afforded by relapses occurring months after the operation. 6. Of the permanent cures some may well be instances of permanent advantage derived from reduced congestion. 7. The clinical evidence as to the actual atrophy of the prostate after castration lacks, as yet, its scientific confirmation, and has failed thus far to prove its title to the surgeon's credence. [M.B.T.]

2.—Knopf recommends that the medical colleges in medical centers should combine in the use of all **clinical material** in their city, and that all medical men attached to hospitals should be clinical teachers independent of college affiliations. Hospital physicians should be appointed only

when well qualified both as clinicians and teachers. Other details are suggested. [D.L.E.]

3.—In a lengthy article Ranney concludes as follows: 1. A small percentage of subjects in whom **cross-eye** exists owe their existing disfigurement entirely to errors of refraction. Proper glasses alone will correct the disfigurement of such patients. Extreme nervous phenomena may coexist in this type of case with the cross-eye, and disappear entirely when the refractive correction is properly made by glasses. 2. Extreme and constant disfigurement from cross eye, which does not prove to be the result of refractive errors, does not as a rule entail eye-strain or tend to create reflex nervous disturbances. 3. Those who suffer only occasionally from cross-eye and at other times show no cast are peculiarly liable to reflex nervous diseases. 4. Extreme cross-eye inward or outward (convergent or divergent squint) is occasionally due to the fact that both eyes are adjusted either too high or too low in the orbit. 5. Some subjects are unconsciously able to adjust for very high degrees of "latent" squint, and actually to maintain binocular single vision most of the time. The red-glass test in such cases usually develops unconquerable diplopia at once. 6. The "phorometer" and "tropometer" are often essential to the proper recognition of the causes of cross-eye and the particular muscles at fault in individual cases. 7. The "exclusion test" is of great value in cases of squint. It is often extremely difficult and sometimes almost impossible to teach patients afflicted with cross-eye to abandon their unconscious habit of suppressing visual images. The "exclusion test" then becomes the chief reliance of the oculist in determining both the form and degree of maladjustment that exists, and in many instances which operative step to take first. 8. When vertical and lateral squint coexist, it is usually wise to correct the vertical maladjustment (either entirely or in part) prior to operation upon the lateral muscles. 9. The old methods employed in operating for cross-eye have been so modified since the discovery of cocaine that the most extreme deformities can be rectified today without pain and even with no confinement to the house. [M.B.T.]

4.—Gillette reports the sixth successful case of **Porro-Cesarean section**, so far as he is able to learn, in the State of Ohio. A fibroid tumor the size of a child's head so blocked the pelvic outlet as to render it difficult to reach the cervix, and it was so impacted by the contractions of the uterus that it could not be moved at all. The patient was operated upon 60 hours after labor began. A healthy living child was delivered through an incision in the uterus, after which the tumor was with difficulty enucleated from its position, a rubber ligature thrown about the cervix, thus controlling hemorrhage, and the uterus amputated. The patient made a good recovery and was able to nurse her child. [W.K.]

6. The Continued Use of the Antiseptic and Elimination Treatment of Typhoid Fever Without Any Deaths. T. VIRGIL HUBBARD.
7. Brief Notes on Rheumatic Joints Treated by Hot Air. HOMER GIBNEY.

1.—Hare calls attention to two groups of cases, viz.: (1) Cases in which symptoms, developing in the neighborhood of the appendix, indicate the rapid development of **appendicitis**, yet in which these symptoms gradually subside and the patient passes into an attack of **typhoid fever**, and (2) cases already well advanced in the progress of typhoid fever which develop appendicular symptoms. He illustrates the first group by citing the case of a young man of 21 who had not been feeling well for several weeks, and

who suffered from headache. On being admitted to the hospital he developed the typical symptoms of appendicitis. Keen and Hearn agreed with the author that the symptoms were those of appendicitis, but as now the tongue appeared typhoidal operation was postponed and under the use of mild salines and an ice-bag to the region of the appendix all symptoms of appendicitis passed away and an otherwise typical attack of typhoid fever set in. Another case running a very similar course was cited. The author says he has met these cases now so frequently that he no longer considers them rare. He is of opinion that one of two conditions may be present at the caput coli, viz.: (1) There is ordinary appendicitis due to the pathologic conditions which produce this disease which happens to occur simultaneously with the onset of the typhoid fever, or (2) the case may be one of those in which the general symptoms of typhoid are mild, yet the intestinal lesions are marked. To make a differential diagnosis is very difficult if not well nigh impossible, but the author thinks a blood count will often assist to make the diagnosis, as it is well known that in appendicitis there is marked leukocytosis, but this is not the case in typhoid fever. [A.B.C.]

2.—Cunningham discusses the various **animal extracts** that are obtained from the organs of animals. He calls attention to the fact that during their preparation, which often involves serious delays, opportunity is offered for numerous chemical changes to occur. The pituitary body apparently causes an increased katabolism of tissues rich in phosphorus and poor in nitrogen. It has been most frequently used in akromegaly, and in some cases, Cunningham thinks, it has served to reduce the headache. It often causes increase in weight in cachectic subjects. Adrenal extract does not appear to be poisonous or even to have much effect if taken by the alimentary tract. Locally, as is well known, it produces increase of blood-pressure. In 24 cases of Addison's disease collected by Cunningham, 14 were temporarily improved and 10 unaffected by the administration of the gland. It seems to be of some use in exophthalmic goiter, although Cunningham's own results have not been encouraging. The thymus had been used in exophthalmic goiter with occasional good results—that is, in 3 of 10 cases treated by Cunningham. It causes increase in weight. Occasionally the thyroid is substituted for the thymus by the apothecary. The thyroid gland has a distinct action and causes the well-known symptoms of thyroidism. The interesting part of Cunningham's communication is the statement he makes, that in many cases of myxedema the purified colloid obtained by Hutchinson's method is far more efficacious in reducing the diseased condition and does not produce toxic symptoms. He does not regard the iodothyron as a very active preparation. [J.S.]

3.—Wilson advocates the use of large doses of the **sirup of the iodid of iron** in various forms of **infectious arthritis** and cites the following cases. A girl, 18 years of age, had polyarticular rheumatism, followed by signs of intraarticular effusion in the knee. There was marked leukocytosis. The knee was finally aspirated and the fluid yielded a growth of staphylococci. There was also a severe leukorrhea. As sodium salicylate failed to have any effect upon the case, she was given the iodid of iron, and in the course of a few days there was notable improvement, and finally the patient was completely cured. The maximum dose was about a teaspoonful 4 times a day. The second case, a man of 22, had had specific urethritis, and about a year later developed stiffness of the joints and finally swelling and pain in the knee-joints. As salophen was ineffective, iodid of iron was commenced and led to rapid recovery. The third patient, a similar case, yielded also to the treatment. [J.S.]

4.—Kellogg states that **moulds** are very frequently found in the stomach-contents, 457 times in 7,000 analyses made by him. Among those found were the *Oidium lactis* which enters with milk, the *Aspergillus fumigatus* and *A. flavescens*, which apparently enter with bread. These moulds seem to have an injurious effect in some instances, and in Italy produce the disease known as pellagra. In one case of hypopoesia, 800 colonies were found in 1 ccm. of fluid. [J.S.]

5.—Goldan describes an apparatus for the administration of nitrous oxid gas alone or in combination with ether. Illustrations accompany the description. [A.B.C.]

6.—Hubbard describes the antiseptic and eliminative

treatment of **typhoid fever** which he has used with great success in his practice. This consists of giving when first called to the case a capsule containing calomel $\frac{1}{2}$ gr., guaiacol carbonate 2 grs., podophyllin $\frac{1}{10}$ gr. to $\frac{1}{4}$ gr. every two hours for one or two days or until four or five evacuations have been obtained for two successive days. When these have occurred the calomel is replaced by $\frac{1}{2}$ gr. of menthol. Constipation is then checked by the administration of Hunyadi water or salts. If the temperature remains high at the end of five days the calomel is repeated. If the skin and kidneys fail to act well enteroclysis with normal salt-solution is employed. Antiseptics do not get rid of all the bacteria; nevertheless, they serve to get rid of a very large number of them, and therefore to diminish the strain upon the tissues of the patient. The ulceration of the bowel is of course merely a local symptom and not in the majority of cases the most serious element in the disease. Therefore, as the poison of typhoid fever is to be found in almost every tissue of the body, and as there is no direct chemical antidote to it, it is important to aid its elimination as much as possible. Hubbard's statistics include the results of 20 cases which he treated by this method without any deaths. The improvement is usually most marked in the general condition of the patient. [J.S.]

7.—Gibney reports a number of cases treated by the **hot-air method**. They involve various forms of chronic joint-disease and all were very much improved by the treatment. [J.S.]

Boston Medical and Surgical Journal.

July 19, 1900. [Vol. cxliii, No. 3.]

1. Milk; Its Production, Its Care, Its Use. T. M. ROTCH.
2. General Remarks on the Pathology and Symptomatology of Acute Pelvic Suppurative Processes in the Female and Their Treatment by Posterior Colpotomy. CHAS. GREENE CUMSTON.
3. Parturition Complicated with Suppurating Fibroids. E. H. STEVENS.
4. Glandulopenile Hypospadias; Two Urethras, One Extending to the Bladder, the Other $2\frac{1}{2}$ Inches Long and Terminating in a Blind Pouch. J. COPLIN STINSON.

3.—Stevens reports a case of **suppurating fibroids** as a complication of pregnancy. A patient of 39 had been married 10 years. There was a miscarriage at 3 months 9 years ago. Her health was always good until about 16, previous to her confinement. She was delivered of a healthy female child weighing about 8 pounds, 20 hours later was awakened with a chill. Other chills followed later, and a complete hysterectomy was done on the seventeenth day. The patient died on the twenty-first day with a temperature toward the last of 106° . She had suffered greatly from a rash which covered the entire body and finally became confluent, resembling the rash following the injection of diphtheric antitoxin. Antistreptococcus serum had been used and the question suggested to Stevens was whether it had done harm. He did not believe it had, although he thought it did no good. At the first warning of trouble the uterus and vagina were thoroughly cleansed, and the patient's condition appeared hopeful for some time. He, however, believes an earlier operation in such cases would be better. [W.K.]

4.—Stinson reports the case of a youth of 17 having **hypospadias**. At 15 he had gonorrhea, but there was no operation on the urethra or penis. The glans penis is drawn downward and is fixed at about a right angle to the shaft of the penis. This is probably due to adhesions, and contraction of scar tissues. There are two urethras, one extending to the bladder, the other $2\frac{1}{2}$ inches long passing parallel with the main tube, but ending in a blind pouch. The external orifice of urinary urethra is situated in the penile urethra about one-half inch posterior to proximal portion of glans; the opening is small, admitting about a 16 French sound. It is situated slightly to the right side of median line. The canal of urinary urethra is apparently of normal caliber. The incomplete urethra is situated close to the left of the urinary urethra. Its external orifice is small, but readily admits the bulbous end of a pocket-case probe, which passes downward along the median line for $2\frac{1}{2}$ inches, where it terminates in a blind pouch which does not communicate with the urinary urethra. [M.B.T.]

4.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, No. 18, page 993.

5.—Huizinga speaks of the absolute necessity of careful attention being paid to the nasal mucous membrane in many cases of **operation on the tear-ducts** in order to avoid unfavorable results. He does not advocate dilation nor conversion of the canal into a groove in epiphora, but proceeds as follows: The punctum is dilated that a knife made for this operation may be introduced with the least possible injury, for ordinarily it does not need to be cut. Having first ascertained the exact location of the stricture by means of probing, the knife is passed into the canal with the back of the blade firmly hugging the wall of the canaliculus toward the border of the lid, so as to injure the mucous membrane as little as possible. The stricture is cut by a sawing movement. In the lower canaliculus the cut is made downward, and in the upper it is made upward. In this way little or nothing is cut except the stricture, and the direction in which it is cut is such that it in no wise interferes with the proper physiologic function of the organ. The after-treatment consists of irrigations with boric-acid solutions and the regular use of a No. 8 Bowman probe. [M.B.T.]

6.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, No. 23, page 1288.

7.—Leonard, in speaking of the **advantages gained through the use of the x-ray**, particularly alludes to the avoidance of much interference with dressings in cases of fractures, and the obtaining of definite and absolute knowledge in fracture examination, without pain or discomfort to the patient. By the x-ray many forms of apparatus to produce immobility have been shown useless. Great variations have been shown to exist from the representations in textbooks, enforcing attention to the necessity for careful study of the mechanical elements involved in each fracture. So called inaccuracies and fallacies of the x-ray are usually due to errors in technic. Skiagraphs do not form any basis from which to assess damage in suits at law, since disability does not necessarily depend upon a symmetry which can be shown, but often upon lesions of the soft tissues that cannot be recognized in a skiagraph. The x-ray is especially valuable in the diagnosis of renal calculi, affording opportunity for operation early, when the mortality is but 2% or 3%, instead of waiting until danger from suppuration increases the mortality to even 25%. The exact localization of the calculus is of great advantage, limiting the field of operation. In vesical calculi the method of diagnosis is valuable, determining the size and number of calculi present, in showing partially encysted calculi lying in a diverticulum, or in detecting calculi in the pocket behind an enlarged prostate gland. [M.B.T.]

8.—Abraham emphasizes the fact that the tonsils are the portals through which many pathogenic microorganisms enter the system, reviewing the literature and citing cases.

He advocates careful investigation of each case of **tonsillar disease**, treating the attacks energetically. Pus should be evacuated so soon as demonstrated. The isolation of all cases of acute lacunar tonsillitis is advisable, since this is an infectious disease. Recurring attacks of acute tonsillitis are an indication for the partial or complete removal of the tonsils. A careful systematic examination and treatment should be applied during and after an attack of acute tonsillitis. [M.B.T.]

9.—Dock relates a case of **sarcoma of the stomach** in which the patient did not present features admitting of a differential diagnosis, and diagnosis of dilation from tumor at the pylorus, probably in the scar of an old ulcer, was made. The patient laid much stress on the history of a paroxysmal pain, with a soreness in the epigastrium, vomiting, etc. Although there was no history of hemorrhage, the symptoms in the early stages had not been carefully observed. There was evidently an adhesion between the liver and the stomach tumor, and on account of the history, long duration and absence of more positive evidences of malignancy, this pointed rather to a hypertrophic scar than to a new growth. Pylorotomy was done February 5, 1900. The part removed represented about one-third of the long axis of the stomach and about 2 cm. of the duodenum, while the tissue seemed to be well clear of new growth at its extremities. No metastases could be found, and uninterrupted recovery followed the operation. Microscopic examination of the tissue removed showed it to be a lymphosarcoma with a well-developed reticulum containing small cells in its meshes. Dock reviews the literature, and establishes the fact that diagnosis of the condition has rarely been made in life. Enlargement of the spleen and swelling of the follicles of the tongue, thought to be common in lymphosarcoma, may sometimes enable one to recognize gastric sarcoma correctly in a late stage, but so far as the earlier stages are concerned we have no specific symptoms of sarcoma of the stomach, and even when tumor is present it can not be positively differentiated from cancer. It is important to discover the affection of the wall early and if possible to carry out either radical or palliative operative treatment, without taking time to make a histologic diagnosis from the clinical features. [M.B.T.]

1. A Case of Carcinoma of the Esophagus Treated by Canula. C. A. EWALD.
2. Changes in the Cells of the Pyramidal Tracts in Paraplegia. G. MARINESCU.
3. Experience with Diseases of the Pancreas. J. ISRAEL.
4. Symptomatology of Hysterical Deafness. ERNST BARTIL.

1.—Ewald reports an interesting case of **carcinoma of the esophagus**, treated by leaving a canula in place so the fluid might pass through the constriction into the stomach. The patient was 64 years of age. He had noticed dysphagia for about a year previous to his entrance into the hospital. The lumen at the constriction was so small as to only allow a bougie about the size of a small leadpencil to pass through; consequently a canula was inserted and left in situ. The patient felt easier and could swallow with greater facility, and gained about 3.1 kg. in weight. Up to the time of death he never experienced any difficulty or discomfort from the presence of the canula. [O.B.W.]

2.—The changes described consisted in **atrophy** and disappearance of the ganglion cells in the cortex about the fissure of Rolando, more particularly in the upper third. They were replaced by granular neuroglia cells. The question was as to whether the cortical lesions were primary or secondary to degeneration of the pyramidal fibers. The second view is considered most probable. [D.L.E.]

3.—Israel first reports a highly interesting case in which the entire pancreas was found to be extremely movable. The nature of the mass was not known until operation was undertaken. When the patient was lying upon her back there was a sensitive tumor in the epigastrium, but when the body position was changed it moved about with the greatest ease and very widely, the limits of its movement varying between the middle line and the anterior axillary line, and

vertically from the level of the eighth rib to the level of the twelfth rib. Operation showed that there was a pancreatic cyst, and that the pancreas itself was extremely mobile. It is the first case of movable pancreas reported. The second case reported was one of movable pancreatic cyst. This was curious also in the fact that the contents of the cyst showed the presence of no ferments, but the fluid coming from the fistula some days after operation contained ferments. The other case was interesting because aspiration of the cyst resulted in complete cure. In the fourth case operation disclosed pancreatic necrosis with peripancreatic abscess. [G.B.W.]

4.—The case reported occurred in a girl who had previously had an attack of complete deafness following an emotional shock which had spontaneously disappeared. The attack which was described was similar in its onset, and it also vanished very suddenly. The diagnosis of the hysterical nature was rendered more secure by the interesting observation which is reported. The child was entirely deaf to words and apparently to all other sounds with the exception of the fact that she could sing various songs entirely correctly, giving the proper musical tones and intervals, and if a note was struck on the piano she always began her song in the same key. If the key were changed she sang in the corresponding key, always correctly, and if the key were suddenly changed with the second verse of the song she also changed her key properly. In spite of this she could not hear piano music. This is considered an interesting confirmation of the belief that hysterical anesthesia, whether it is of touch or of sound, is a purely psychic anesthesia. This child had no conscious perception of sounds, but she evidently appreciated sound unconsciously. [D.L.E.]

June 7, 1900. [26. Jahrg., No. 23.]

1. A Case of Aneurysm of the Abdominal Aorta. E. v. LEYDEN.
2. Two Cases of Cortical Epilepsy with Operative Treatment. M. A. LUNZ.
3. Concerning Relapses. LIPPMAN.
4. Oxidation Ferments. H. STEUDAL.
5. Autoinsufflation of the Stomach. C. D. SPIVAK.

1.—Leyden describes a case of **aneurysm of the aorta** which was easily diagnosed, a round tumor with expansile pulsation being readily felt. An interesting point in the case was the observation of a marked diastolic murmur which was heard even to the region of the aortic orifice. There were none of the signs of aortic regurgitation, and the tumor decreased in intensity as one advanced upward in ausculting. It was, therefore, attributed to the aneurysm. Such cases have been reported before, particularly by Scheele, and Leyden believes that these authors' explanation of the occurrence of the murmur is correct, *i e*, that the opening in the aneurysm is narrower than the lumen of the aorta above. The result of this is that during diastole the blood flows upward in the aorta from the aneurysm, and thus produces the murmur. [D.L.E.]

2.—Lunz reports two cases of **cortical epilepsy**, both of which were operated upon. The first was a woman of 53, who began to have epileptoid seizures $2\frac{1}{2}$ years previous to her entrance into the hospital. Examination showed slight paresis of motion of the left arm and left leg, though sensation was normal. She was in the hospital 7 months before operation, during which time she had 19 attacks. The attacks began by jerking of the left toe and spread upwards until finally unconsciousness occurred. Operation consisted in turning down an osteoplastic flap from over the region of Rolando's fissure. No pathologic conditions except a slight adhesion between the dura and the skull could be found, so the dura was reunited and the osteoplastic flap put back into place. The wound healed in 12 days, and for 4 months after the operation there were only one or two insignificant convulsions noticed. Case No. 2 was a woman 22 years old, whose attacks began about 6 months previous to her admission to the hospital. There was considerable loss of power in the right hand, while movement of the head, especially bending forwards, caused dizziness. The epileptic attacks were very frequent and very severe; they generally began by jerking at the right angle of the mouth or in the right side of the face. Bromids and antisyphilitic medication were given without result, and operation was decided upon. A large

osteoplastic flap was turned down from over the region of the fissure of Rolando and of Sylvius; there were adhesions between the pia and dura mater and a diseased area about the size of a walnut was found in the lower part of the central gyrus. Another area of softening about the size of a pea was found just above the Sylvian fissure. The diseased areas were carefully removed, and the adhesions between the dura and pia excised. The wound healed by first intention, and for a while the patient was free from attacks, but in 2 months the attacks returned to almost their former severity. [G.B.W.]

1. The Tonsils probably the Entrance Gate for Tuberculosis Infection in Young Children. F. F. FRIEDMANN.
2. Does Night Work Cause Amblyopia? P. SILEX.
3. Dangers of Lumbar Puncture. F. GUMPRECHT.
4. Isolated Deltoid Paralysis. ADOLPH STEINHAUSEN.
5. Blood Diseases. THEODOR KLEIN.

1.—Friedmann reports his observations of material obtained by necropsy and by tonsillectomy. Of the postmortem material he mentions a case in which there was **tuberculosis of the tonsils** with the usual morphological appearances and with the presence of the tubercle-bacilli, but in which the most careful search showed no evidence of tuberculosis in any other part of the body. This was probably a food tuberculosis. In another case there was tuberculosis of the tonsils with involvement of the glands of the neck, and subsequently general miliary tuberculosis. In another case the tonsils were probably the earliest seat of tuberculosis, with subsequent development of the disease in the cervical and bronchial glands and death from miliary tuberculosis. There were other cases in which the tonsils were probably the primary seat of the disease. There were also a series of cases in which the tonsils were involved but were probably not the primary seat. In all the cases mentioned tubercle-bacilli were found. He describes a series of 7 cases also in which without the presence of tuberculosis elsewhere in the body the typical morphological appearances of tuberculosis were seen in the tonsils, but tubercle-bacilli were not discovered. This case cannot definitely be called tuberculous. There were also 8 cases in which, with extensive tuberculosis of other organs, tuberculosis of the tonsils was seen. In 4 cases in which there was tuberculosis of other organs the tonsils were found free from tuberculosis. He also mentions other cases in which, with tuberculosis elsewhere, sections of the tonsils showed the absence of bacilli and of typical morphological changes, but smear-preparations from the surface of the tonsils showed bacilli. This is good evidence that animal injections do not provide satisfactory evidence of tuberculous disease of the tonsils. As to the material from living cases, there were 46 instances in which no evidences of tuberculosis were seen, and in 6 cases with marked enlargement of the glands of the neck the results were likewise negative. In 1 case the result was doubtful, and in 1 case in an apparently healthy child one tonsil was found to be tuberculous. The conclusions which he reaches are that tonsillar tuberculosis may arise from primary local infection from the food, and from a secondary infection through the sputum. The first method of infection has been considered questionable, but some of the cases, particularly the first one mentioned, seemed to prove its existence as well as it can be proved, and he believes that tonsillar tuberculosis in children usually comes from the food. [D.L.E.]

3.—Gumprecht calls attention to the possibility of **death following lumbar puncture**. One accident which he says is very liable to happen, and to which little attention has been drawn, is the breaking of the needle by some movement of the patient or doctor. In searching through the literature he finds 15 cases of sudden death following tapping of the spine. He reports 2 cases from his own experience. The first case was that of a girl 20 years of age; the puncture was made at 10 o'clock in the morning, when 5 cc. of light cloudy liquid were withdrawn; the pulse became immediately irregular and small, necessitating the withdrawal of the needle; the patient died suddenly at 9.15 the evening of the same day. Necropsy showed dilation of the fourth and lat-

eral ventricles, and a glioma of the right thalamus. The second case was that of a man of 29, who died 2½ hours after the lumbar puncture. Necropsy showed a brain-tumor about the size of an apple, situated on the posterior two-thirds of the thalamus and the splenium of the callosum; and on the quadrigemina. The lateral ventricles of the cerebrum were markedly dilated, especially the inferior horn; though the fourth ventricle was narrow. [G.B.W.]

4.—The case reported presented indubitable evidences of **paralysis of one deltoid** while the other shoulder-muscles were unaffected. Within 3 weeks after the case was first observed, the arm could be raised. There is no other evidence that paralysis of the deltoid does not make adduction of the arm impossible in all cases. Steinhäuser thinks that the previous teaching as to the influence of the scapulohumeral muscles and the scapulothoracic muscles in raising the arm is incorrect. He believes that the deltoid and the other scapulohumeral muscles raise the arm to about 120°, and that the rotators of the scapula carry out the remaining actions, that is, they raise it through only about the upper 60°. Previous teaching has been that the deltoid raises the arm to about 90°, and the serratus does most of the remaining work, that is, carries it through the remaining 90°. As proof of his belief he describes another case in which the deltoid was paralyzed, and in which at the same time there was paralysis of the infraspinatus; the scapula was rotated well in this case, but the arm was scarcely at all abducted, and it was possible to raise it voluntarily only when assistance had been given through about 140° of movement. [D.L.E.]

5.—The case reported is one of **hemophilia** which persisted for years and repeatedly caused very grave hemorrhages. [D.L.E.]

4. The New Nauheimer Saline Spring Rich in Carbonic Acid Gas. Spring No. 14. LEPSIUS and SCOTT.
5. A New Surgical Instrument for the Nose. JAENICKE.

1.—Koch's report contains no facts that are strikingly new or important. He found that, as he had considered probable before, the whole coast of German New Guinea was infected with malaria. Of the French Islands the largest was found entirely free from malaria. In earlier years malaria was present in these islands. In the Island of Dsalaos, however, he found nearly all the children who were examined infected with malaria. He insists again that it is possible by the methods recommended by him to make regions practically free from malaria, but it is of the greatest importance to recognize the obscure latent forms of the disease in order to overcome the possibility of transmission of the disease. [D.L.E.]

2.—Ziemann states that in spite of the investigation of sections of many hundreds of mosquitos in Kamerun he was unable for a long time to find any evidence of the presence of infection with malarial parasites, and had come to doubt the mosquito theory. He found several instances of infection of mosquitos with filaria embryos. Subsequently, however, he found several examples of infection of anopheles with the malarial parasite, and in a number of houses he afterward found infected mosquitos. He observed in the anopheles's stomach pigmented coccidia-like bodies which formed the so-called sporozoids, and they were ultimately found in the salivary glands. [D.L.E.]

3.—The authors report their results from the investigations of the **agglutination reaction for tuberculosis** in a series of cases in which the results were controlled by looking for tubercle bacilli in the sputum and by using the tuberculin test. In all, 73 persons were investigated. There were 17 with beginning tuberculosis of the lungs and 5 who were suspected of tuberculosis and who gave a positive reaction to tuberculin. There were also 2 cases of lupus, 1 of tuberculosis of the kidney, 1 of healed tuberculosis proved by autopsy, and 1 of tuberculous meningitis. In the first group only 6 gave positive agglutination reaction,

and of the 5 suspicious cases only 1 reacted; only 1 of the lupus cases reacted. The case which proved upon postmortem to have healed tuberculosis reacted, but the tubercular meningitis did not. Two cases of leprosy did not react. On the other hand 2 out of 3 cases of croupous pneumonia, 2 out of 3 of bronchitis, 1 of 3 cases of rheumatism, 1 case of cirrhosis of the liver, and 1 healthy person reacted. The other cases investigated were negative. Normal serum which had been inoculated with cholera and typhoid cultures also showed reaction. They decide that the reaction cannot be used in the diagnosis of tuberculosis, that it is not a specific reaction, occurs in men and animals who have not tuberculosis, and is often absent in cases of tuberculosis. [D.L.E.]

5.—Jaenicke suggests an improvement in the ordinary **nasal snare**, which possesses the advantage of allowing the operator to use the same loop over many times and also enables him to enlarge or decrease the size of the loop after the instrument has been inserted into the nose. The difficulty with the older instruments is that the loop is bent to a very sharp angle by its being retracted into the canula. Jaenicke overcomes this by passing the wire through two tubes, the ends of which diverge so that a small bridge 3 mm. in breadth can be placed between the divergent ends. When the loop is tightened the wire is pulled against the bridge and cannot pass into the tubes, this keeps the loop from being bent at a sharp angle, and when it is pushed back it instantly regains its proper oval form. Various modifications are made to suit the different operations in which a snare is needed, and one is adapted for the galvanocautery. [G.B.W.]

Münchener medicinische Wochenschrift.

8. A Mammary Gland on the Thigh. STEMBORN.
9. Cerebral and Cardiac Asthma. O. ROSENBACH.

2.—Kehr in speaking of the **recurrence of symptoms after operation for gallstones** divides them into the true and pseudo relapses. The former consisting of a redevelopment of the stones and the latter of symptoms due to the intentional or unintentional leaving of one or more stones in the gall-passages, to renewed inflammation of the gallbladder, to the formation of adhesions, or to the development of a hernia in the seat of the wound. Kehr says that he has never seen a true relapse in which the formation of new stones has taken place and therefore will confine his remarks to the pseudo forms. First as regards leaving concretions in the gall-passages after the operation; this he has done 19 times in 491 laparotomies for the removal of gallstones, but he believes this can be overcome in the future by a more thorough technic. In 12 cases a return of an inflammation of the gallbladder was observed and in each of these, cultures showed the presence of the *Bacterium coli* and they were cured by reestablishing drainage for a few weeks. In 302 operations hernia followed in 21, i. e., in 7% of the cases collected. The most frequent source, however, for the return of symptoms is the formation of adhesions. Eleven per cent. of the cases showed this condition, but by far the greater part of these followed cystostomy, while cystectomy and choledochotomy gave very little trouble from this source. Because of the above possibilities it should be the duty of the surgeon, to be sure of his diagnosis, to choose a method of operating which will make the removal of all the stones possible and prevent the subsequent development of inflammation, to limit the adhesions to the smallest amount possible, to prevent hernia, and by proper diet and hygiene to stop the barely possible formation of new stones. [G.B.W.]

3.—Dinkler has made studies on 2 fatal cases of **Graves' disease**. One was complicated with hemiplegic and bulbar

and psychic symptoms. In the other a unilateral strumectomy was done on account of compression of the trachea by the goiter. The patient died twelve hours after operation. In the first case, contrary to the observations of others in similar cases, the author found, but only with Marchi's method, decided changes in the central nervous system. Regarding the thyroid gland, the first case showed those features usually characteristic of Graves' disease, viz., the formation of solid epithelial ducts and alveoli. In the second case, in which there was an enormous hyperplasia of the thymus also, the thyroid showed follicles like those of the normal gland, and the author believes that the microscopic picture of the thyroid in exophthalmic goiter probably depends on the condition of the thymus. The more marked the hyperplasia of the latter the less atypic is the structure of the thyroid gland. There was no increase in the arteries of the gland in either case, but the veins and capillaries were much dilated. He agrees with Moebius in considering exophthalmic goiter of thyrogenic origin. [D.R.]

5.—The characteristic features of **hysteric aphonia** are: 1. Exclusive involvement of the constrictors of the glottis, some of the modes of voice-production being still preserved. 2. Disturbances in sensation in the pharynx and at the entrance of the larynx. 3. Preservation of the electric and reflex excitability of the laryngeal muscles. A cure of hysteric aphonia is sometimes achieved by psychic emotion, such as fear, fright, or rage. Sometimes it may be relieved by massage of the larynx or compression of the thyroid cartilage or hyoid bone. Sprays, inhalations, and local applications may be of value, but the surest method is treatment with **electricity**, especially the faradic current. Anesthesia, cold douches, venesection, and apomorphin occasionally do good. Relapses are apt to occur, and the more often they occur, the more hopeless is the prognosis as regards cure. It is well after a cure has been achieved to use the faradic current daily for from 1 to 2 weeks. [D.R.]

6.—Bayer reports an interesting case of **ophthalmia caused by the hairs of a caterpillar**. The patient while baying was struck in the eye by a large brown caterpillar. Immediately the patient experienced a sharp, burning pain in the upper lid, which did not disappear, though it became somewhat better after 10 days or so. Three months after the accident he presented himself at the clinic, when it was found that he was suffering from ophthalmia nodosa of the cornea and iris, complicated by an iritis plastica. The treatment consisted in the application of leeches and the instillation of atropin, later in the temporary widening of the palpebral fissure and a careful paracentesis of the anterior chamber. The eye was greatly improved, though not entirely cured, by this treatment, and on close inspection two brownish bodies were seen in the lower nasal quadrant imbedded in the deeper layers, which bodies proved, on closer examination, to be hairs from the caterpillar. [G.B.W.]

9.—A lengthy speculative article in which the author discusses the so-called **cerebral asthma and nightmare**. [D.R.]

5. Two Cases of Congenital Malformation. WOLF.
6. Investigations of Rhodan Compounds. G. TREUPEL and A. EDINGER.
7. Conditions Found After Death by Strangulation. MESSENER.

2.—**Ferratogen** is useful in **chlorosis** in those cases in which the stomach rebels against iron preparations. The drug is prepared by the manufacturers in the following way: Yeast is cultivated on a ferruginous medium. The iron-nuclein formed is isolated, digested with gastric juice, and then washed with acid alcohol until the iron reaction disappears. The preparation contains about 1% of iron. [D.R.]

3.—The author reports a case of **beriberi** presenting characteristically the symptoms of multiple neuritis. There was protracted anesthesia, particularly on the inside of the legs, even after convalescence. The patient had been attacked on board a sailing vessel after leaving India. Several

other members of the crew had the disease, which in the beginning was associated with symptoms resembling scurvy. The disease did not develop until 3 months after the ship had left the harbor where beriberi was prevalent. All of the 5 seamen attacked were Germans, an argument against the prevailing view that Europeans are immune to beriberi. [D.R.]

4.—Bezold reports three interesting cases of **intracranial suppuration in acute middle-ear disease**, and emphasizes the importance of acute disease of the ear in the causation of intracranial suppuration. In the first case, within 4 weeks after an acute otitis media, symptoms of sinus-phlebitis, pyemia, and metastatic foci in the lungs developed. Two operations were done and the patient recovered. In the second case an acute middle-ear disease had developed after erysipelas. The mastoid was opened. As the fever did not subside a further operation was done and the lateral sinus was laid bare and punctured. Normal blood appeared and nothing further was done. The patient recovered. The third case was one in which a cerebral abscess complicated an acute otitis media. A timely operation saved the patient's life. [D.R.]

5.—A family in which the mother and 2 children were born **without patellas**. The grandchildren possessed this bone. The movability of the kneejoint in the apatellar members was unimpaired, but the joint easily became tired. The 3 persons were also without thumb nails. The second case concerned a family in which a large number of members had a deformity of the hand, consisting in ankylosis of the first interphalangeal joint of the little finger. [D.R.]

6.—The authors found in a very careful series of experiments that **sulphocyanid of sodium** had no bactericidal or bacterio-inhibitory action. [D.R.]

7.—A very interesting essay on the **pathology of suffocation** through action on the neck. Rapid suffocation through mechanical causes can be brought about in various ways: It occurs in diphtheria, in edema of the glottis, in spasm of the glottis, in pressure from goiter, and through foreign bodies. Mechanical suffocation is sometimes also brought about through holding the mouth and nose closed, or in some cases the mouth has been stuffed with hay. The aspiration of vomited material or of blood can produce suffocation. It can further be brought about through drowning, and by compression of the thorax in crowds or under heavy banks of earth. Suffocation may also result from mechanical influences acting on the neck from without. This form is known as death through **strangulation**, and is divisible into 3 sub-forms—hanging, strangling, and throttling. The first two are brought about through the medium of a rope, and the last through that of the hand or hands. In all 3 forms the suffocation is caused by pressure of the base of the tongue against the wall of the pharynx, also at times by closure of the glottis. In hanging and strangling there is in addition a closure of the carotids, which explains the rapid oncoming of unconsciousness in those modes of death. Frequently the external marks permit a conclusion as to the manner of death. In hanging and strangling there is a mark on the neck—**rope-mark**. There are two kinds—the pale or soft, and the yellow or leathery rope-mark. The mark in the case of hanging is situated higher up on the neck than the strangling mark. The former shows at some part of the neck an interruption, while the strangling mark is continued. In throttling there are usually finger-marks to be found. The general lesions in strangulation are those of **suffocation**. These are cyanosis, hemorrhages in the skin and mucous membranes, occasionally incarceration of the tongue between the teeth. The blood is fluid and dark. Echyloses are seen on the serous surfaces; there is stasis hyperemia in the lungs, injection of the mucous membrane of the bronchi, trachea, and larynx; also stasis hyperemia in other organs, especially the brain, kidneys, etc. When a body is found it is often important to determine whether there has been a crime, a suicide, or an accident. Usually the question is between suicide and homicide. Hanging is a very common mode of suicide because it is easy. Strangling is also occasionally a method of suicide, while throttling practically never is. It becomes at times a question whether a body that has been found hanging was not hung after having been killed. The points to be observed are that when a dead body is suspended the signs of suffocation will be absent and there will be no hemorrhages in the neck

as in cases of hanging during life. The rope mark itself does not give any clue. Very difficult are the cases in which postmortem hanging is combined with intravital strangling or throttling. Other points are given by the author aiding in solving important medicolegal questions in this particular field, and by way of illustration a gruesome case is cited in which a burglar strangled three women. [D.R.]

Neurologisches Centralblatt.

June 1, 1900. [19. Jahrg., No. 11]

1. Contribution to the Question of Hereditary Transmission of Acquired Pathological States. OBERSTEINER.
2. Reciprocal Change of the Inequality of the Pupils Produced Experimentally in Progressive Paralysis. PILTZ.
3. A Case of Trumpet Stuttering. KALMUS.

1.—Obersteiner, as a result of a publication of Sommer's, discusses the nature of the **transmission of epilepsy** that occurs in guineapigs. This appears to have been definitely settled not only by the original observations of Brown-Séquard, but also by the confirmatory observations of Westphal and Obersteiner. Therefore, although Sommer was unable to find any trace of epilepsy in 23 descendants, it seems likely that his experiments were not sufficiently extensive. Obersteiner operated upon more than 100 guineapigs and obtained even among them very variable results. Later, Gutnikow and Karplus performed similar operations in the laboratory and found that at least half of the subjected animals had no symptoms at all. It appears curious that the guineapigs have in late years seemed to be so refractory to this operation, and Obersteiner is inclined to ascribe it to the more careful operative antiseptics. Nevertheless he is firmly convinced that acquired pathological conditions may be transmitted to the descendants. [J.S.]

2.—Piltz in this portion of his paper gives the conclusions that he was able to deduce from his experiments as follows: There is a **congenital inequality of the pupils** that may experimentally be altered as a result of the fact that reaction to light and accommodation varies in the two sides. In progressive paralysis this alteration may be produced by altering the illumination, by altering the accommodation, or by voluntarily closing the eye. When one pupil reacts to light and the other does not the illumination of the immobile pupil may cause a consensual contraction in the other. He gives a little diagram to explain the course of the light-reflex which to his mind shows that we must assume direct communication between the centers of the sphincter on either side. [J.S.]

3.—Kalmus, in continuing the consideration of his case, calls attention to the similarity of the symptoms suffered by the patient (temporary spasm of the lips when attempting to play the horn) to those manifested by stutterers. The lips, mouth, and accompanying parts resemble very closely the mechanism of the larynx. The spasms usually remain local. Sometimes, however, they involve the muscles of respiration and occasionally are accompanied by movements of the other parts of the body. There are numerous stigmata of degeneration. Nevertheless, careful treatment according to Guntzmann's method practically cured the patient in the course of five weeks. It appears, therefore, that this was a true case of **trumpet stuttering** and to be compared with the neuroses, such as writer's cramp. [J.S.]

June 15, 1900. [19. Jahrg., No. 12.]

1. The Vicarious Functions of the Muscles Arising from the Condyles of the Arm in Cases of Complete Paralysis of the Proper Plexus of the Forearm. BERNHARDT.
2. Isolated Atrophic Paralysis of the Musculocutaneous Nerve with Remarks upon Compensatory Muscular Activity. HOFFMANN.
3. Phosphorus Neuritis. HENSCHEN.

1.—The case reported by Bernhardt concerns a man of 28, who was attacked by roughs, knocked unconscious, and fell upon the right shoulder. When he arose he noticed that he could not move his right arm. Careful examination showed that there was **atrophy of the muscles** of the shoulder, of the muscles of the fossae of the spine, of the scapulae, of

the biceps, and of the brachialis. Nevertheless, flexion of the arm was readily performed whether the arm was in pronation or supination and whether the hands were flexed or not. As the supinator longus remained completely relaxed during this operation, the only muscles that could be active were those arising from the inner condyle of the humerus, that is, the flexor carpi ulnaris and the flexor digitorum profundus. Bernhardt has observed this condition in two other cases. The case was evidently one of traumatic paralysis of the brachial plexus. He is unable to decide whether it was due to compression of the plexus between the clavicle and the first rib or between the clavicle and the processes of the fifth and sixth cervical vertebrae. He calls attention to the interesting fact that Erb's point for the electrical stimulation of the brachial plexus was situated somewhat below its usual position. The electrical reactions of the muscles were normal. [J.S.]

2.—The patient, a man of 36, was accustomed to carrying heavy baskets on the left shoulder, supporting them with the right arm held above the head. After 2 years of this work, he noticed severe pains in the right arm, followed by gradual diminution in the force of the muscles. When examined some months later, it was found that the biceps and brachialis internus were almost completely atrophied. There was slight contraction of the biceps, and the arm was usually held in a position of semiflexion. Flexion, however, could be readily accomplished by the supinator longus and accessory muscles. There was, in addition, a slight area of anesthesia on the radial side of the forearm. The case represents a **paralysis of the musculocutaneous nerve** which had probably become severe on account of the neglect of treatment. [J.S.]

3.—Henschen reports 6 cases of **phosphorus poisoning**, in all of which nervous symptoms were present. These varied from slight paresthesia in the extremities to multiple neuridites with distinct paralyses. Curiously enough, in some of the cases—as, for example, the second—there was distinct extensive hyperalgesia; in several there was some dissociation of sensation, particularly a slight disturbance of the temperature-sense. In the sixth case all the symptoms were most intense. The patient had taken 3 small doses of the drug, and a month later suffered from severe pains in the back. There were extensive paresthesia and pains and slight diminution in the tactile and temperature senses, associated with extreme hyperalgesia, particularly along the course of the nerve-trunks. From time to time there were twitchings in the left arm, associated with weakness in the same member. The patient recovered completely. Although the presence of hyperalgesia (and we might add disturbance of the temperature-sense) might possibly indicate some central involvement, Henschen is inclined to regard the alterations as due essentially to a neuritis. [J.S.]

11.—Enderlin has carried out a series of experiments on cats and dogs to determine the practicability of **covering defects of the stomach-wall** by transplanting a portion of the omentum. His results show: 1. That it is possible to

close defects of the stomach-wall by transplanting the omentum. 2. That defects produced experimentally are lessened by the contraction of the stomach and by the shrinking of the transplanted omentum. 3. The transplanted omentum becomes covered with epithelium, and this epithelium is cylindric in type. 4. Within 6 weeks there is a formation of tubules, which tubules differ greatly in size and may possess a marked spiral form. 5. Mother-cells and investing-cells disappear before the sixty-eighth day. [G.B.W.]

3.—Stierlin reports an interesting case of **bullet-wound of the skull**, occurring in a man of 34 years of age, who had committed suicide. The bullet did not penetrate but simply grazed the skull, causing a linear defect with more or less comminution of the surrounding bone. The brain-substance escaped from the wound. The patient died a few days after the injury, and at the postmortem a large cerebral contusion was found in the region of the fracture, with numerous splinters of bone scattered through the brain-substance. A most interesting and also unusual finding was an oval fracture of the roof of both orbits. There was a contused area in the temporal lobe, directly opposite the seat of injury. Stierlin, in looking over the literature of cases in which there has been fracture of the orbit, following injuries to the skull, finds 22 cases in which the orbital roof was in some manner involved in the fracture. The production of fracture of the orbital roof in these cases is probably due to the fact that this portion of the skull is the thinnest part, and that when the internal pressure is heightened by the compact of the bullet it naturally gives way. Various writers have taken exception to this theory, but the pathologic findings in Stierlin's case strongly support the above idea. [G.B.W.]

13.—Noesske has written an elaborate article on the part played by **eosinophile cells** and the medulla of bones in the various **surgical infectious diseases**, and also as to their occurrence in tumors. He says that under certain conditions the growth of the tubercle-bacillus in rabbits assumes a form very like that of the actinomyces boy's, and terms it the ray-fungus form. In the earlier stages of this fungus form, that is after 10 or 25 days, an accumulation of granular substance is formed, which granules stain very markedly with eosin. These granules disappear as the disease grows older. The various staining methods show that these granules are typical acidophiles, and probably are granules from disintegrated eosinophile cells. Further research showed that these eosinophile bodies were not identical with the substance of the fungus-like growth, but on the other hand it was found that in all those cases in which the ray-fungus form was not produced the eosinophile cells and granules were either very few or entirely absent. It is most probable that the production of these eosinophiles did not follow any known rule, but was due to some reaction process on the part of the diseased organism, still unknown to science. It has not been possible in any fatal cases of pyemia produced by the staphylococcus or streptococcus to find eosinophile cells in any large amount, and indeed it seems most probable that there is a lessening instead of an increase of these cells. It is found that in subacute and chronic miliary tuberculosis the internal organs show great scarcity of the eosinophile cells, and in chronic tuberculosis of the lungs there is a like scarcity. There does not seem to be any relation between the formation of these cells and the extent and destructiveness of the tubercular processes. The eosinophile cells are also very scarce in the fatal cases of pyemia and septic diseases in man. The increase of the eosinophiles in the blood and cells in the individual organs does not hold any relation to the number of other leukocytes, so that accumulation in the blood of the eosinophile cells, in cases of disease of the blood-producing organs, such as the spleen and bone-marrow, is not of any diagnostic value. Careful examination of numerous tumors, both malignant and benign, show apparently no regularity in the production of eosinophile cells; however, two classes of cases may be distinguished: (1) those in which there are very few or no eosinophiles, including marked inflammatory processes or tumors which are shut off from the external world by the surface of the body, the skin, or mucous membrane, and also benign tumors over which the epidermis is still intact; and (2) those from which these cells are never completely absent, such as tumors of the mucous membrane, *e. g.*, carcinoma of the lip or of cervix uteri. The metastases produced

by this second variety of tumor are, however, as a rule free from the eosinophiles.

As the result of these findings, it seems that the eosinophile cells play the role of protector against the invasion of bacteria as they appear on surfaces exposed to infection. It was found that the eosinophile cells can undergo a retrograde metamorphosis, and it is very possible that the Charcot-Leyden crystals are composed of the remains of these cells. It seems also possible that the eosinophilic granules may be changed into pigment particles, an example of which is found in the fine granular pigment in the cells of the cutis. The correlation, that where an inflammatory process exists there exists eosinophile cells, cannot stand, but the reverse of this may be considered as established, namely, that where eosinophile cells are, there has once been an inflammation. A necrosis does not cause the production of these eosinophile cells but may in fact possess towards them a negative chemotaxis. The eosinophiles are produced as the result of a reaction against a certain localized irritation, and this reaction is a protection against matter which may cause inflammatory processes. As has been shown by Ehrlich, the medulla of bone is responsible for the greater part of the production of the eosinophile cells, and therefore, as shown by the above observations, bone marrow plays a most important role in the protection of the system against the various infections. [G.B.W.]

14.—Bliesner has carried out a large series of experiments to determine the value of **Bardenhauer's "extension method" of treating fractures**. The number of fractures from which he draws his conclusions as to the value of this treatment range upwards of 2,000, dating from 1890 to 1897. In general the idea consists in applying an adhesive strip to the injured member, so that various weights can by means of pulleys be applied so as to cause extension to the lower fragment. In this way he treats fractures of the toes, of the metatarsal bones, of the tarsus and lower leg, thigh, and so on. In the application of the adhesive strips to fractures of the astragalus and the os calcis he used the following method: Two long strips of adhesive plaster, carried on each side of the leg from the knee downwards, are fastened to about 15 pounds of weight; another strip is carried around the angle, crossing over the instep and again over the sole of the foot, forming a figure of 8, and attached to about 4 pounds of weight; directed so as to pull at right angles to the direction of the leg. After about 8 days, massage and passive movements are begun, and in about 14 days the figure of 8 strips are removed. In treatment of the fractures of the malleoli and lower leg the shortening is overcome by extension applied in a direct line with the leg, and the lateral or anteroposterior displacement rectified by extending the foot by some such means as described under fracture of the astragalus. The treatment of fractures of the malleoli last from 2 to 3 weeks, and for fractures of the lower leg from 4 to 6 weeks. In fractures of the femur, extension with from 20 to 30 pounds is used in adults, and in some cases this simple extension is all that is required. Where there is angular deformity some such method as the following is needed: The limb is surrounded by 2 adhesive strips, one broader than the other, and both placed transversely to the axis of the limb; the smaller strip is looped through a slit in the broader one and the limb put through the loop of the smaller strip. The smaller loop is placed so that it passes directly over the point of angular deflection. From 6 to 10 pounds are fastened to the smaller strip, and from 4 to 6 pounds to the larger. The treatment of fracture of the thigh lasts from 5 to 6 weeks. It is very necessary in this extension method of treating fractures that a frequent and careful watch be kept over the parts so that no malpositions shall be formed; the adhesive plaster used should be of good quantity and of sufficient strength. It is claimed for this method that the bones can be kept in the best position with the least disturbance to the functions of the muscles and joints. [G.B.W.]

15.—Deutschländer reports an interesting case of a severe scalp-wound occurring in a Chinaman of 52. The flap which was loosened by the accident carried with it the external ear, separating this from its bony attachment; and in spite of all preventing measures, such as tamponing the external canal, the healing process was attended by complete **closure of the external auditory canal**. After a large granulating surface had been covered with skin-grafts, and the

wound had completely healed, an operation was performed for the relief of the stenosis of the auditory canal. A curved incision was made behind the right ear and the cutaneous portion dissected out of the canal, and the posterior wall cut across close to the insertion of the tympanic membrane. Two parallel incisions were carried from the transverse cut through the posterior wall of the canal, through to the antihelix. The flap thus made was freed from the anterior wall and turned upwards, thus making at the position of the old atresia a space of about one centimeter in diameter. This flap, and the remaining portions of the external ear, were stitched to the posterior wall of the curved incision, and the new canal packed with iodoform gauze. The final result of the operation was most satisfactory. [G.B.W.]

16.—Gerulanos divides the cystic tumors of the external genital organs of the male into four classes: 1. The traumatic epithelial cysts. 2. Adenocystoma, which are true neoplasms and probably originate from the sebaceous glands. 3. Atheroma, which are in a strict sense cysts of the follicles of the skin. 4. Dermoids. He reports a case of **dermoid of the penis** occurring in a boy 6 years of age. The tumor was a sausage-shaped growth, 5 cm. long, situated on the under surface of the penis directly in the middle line corresponding to the median raphe. Under narcosis the tumor was easily removed from its surrounding structures and the wound healed readily by first intention. Examination of the specimen showed the contents of the cyst to consist of horny epithelium, fine debris and cholesterol crystals, but no fat nor fat crystals could be found. The wall of the cyst was composed of stratified epithelium which in some places was folded into papilla-like projections. The diagnosis of dermoid seemed undoubted. [G.B.W.]

17.—Burckhardt writes a rather extensive article on **acute progressive peritonitis**, and reports 11 cases. He divides this progressive peritonitis into 4 groups. The first group consists of those cases in which the infection and inflammation of the peritoneum occurs from the rupture of some extraperitoneal inflammatory center; in the majority of these cases the primary seat of inflammation is in one of the organs of the abdominal cavity which is covered over by peritoneum, though it may possibly come from some external positions. The second group consists of the narrow class of cases in which an encapsulated center of inflammation lying intraperitoneally breaks through the adhesion and gains entrance to the general abdominal cavity. The third group consists of cases in which the inflammation has extended to previously healthy peritoneum from the primary infective centers by means of the lymph-channels; in other words, extension by continuity. An example of this would be suppurative epityphlitis, in which no perforation exists. The fourth group is composed of those cases in which the infective element causes pain outside of the body; such cases are those in which infection follows operative procedures, traumatic perforative wounds of the abdominal cavity, or originate as the result of some other mechanic traumatism. In practice it is very necessary in making a diagnosis not only to recognize that the peritonitis actually exists but also to determine the cause of the infection, as the removal of the primary lesion is the only possible way to stop the progress of the disease. As a help to diagnosis we find that localization of the pain is often confusing, for instance in a case of perforation of the appendix, or when the peritonitis originates from diseases of the uterus or adnexa, the pain is first felt in the region of the umbilicus or stomach. More importance can be attached to the position of greatest tenderness, as elicited by palpation. The severity of the pain does not furnish any measure of the malignancy of the disease; the only symptom which never fails in the later stages of slowly developing cases is meteorism, and when this is present the contour of the abdomen may be somewhat flattened by the action of the abdominal muscle. Fever furnishes very little guide as to the severity of the attack. Likewise the pulse is not a very valuable factor, though cardiac failure of course is always a very serious symptom. As far as operations are concerned for the relief of a progressive peritonitis it is recognized that it is impossible to cleanse an inflamed peritoneum with antiseptic solution, and that the only procedures of value are to remove the infecting center, thus stopping the further entrance of infective material, and to furnish drainage so that all collection of various fluids and secretions may be readily removed. In many

cases this treatment suffices to check the disease, but in many others all operative procedures are useless. [G.B.W.]

18.—Perthes reports an interesting case of **congestion of the neck and head caused by compression of the thorax**. The patient was a woman of 27, who had her body caught between two opposing pieces of machinery which forcibly compressed her abdomen and thorax without touching the upper part of her body. The face and neck instantly became greatly congested and the eyes very much protruded. When brought into the hospital 2 hours after the accident the tissues of the face were swollen and dark blue, and the lids even with the marked exophthalmia present could be separated for only the smallest distance. The black-blue color did not disappear on pressure and was dotted over with small, red, petechial spots. This discoloration extended about half way down the neck and was separated from the normal skin by a very sharp line; it also appeared on the right shoulder and upper arm. There was a fracture of the left clavical and two ribs. The swelling had disappeared by the eighth day, and only a few blotches of the extravasated blood could be seen. In experiments on 2 white rabbits carried out by Braun and Willers, dilation of the veins of the ears and lips were noticed, but no extravasation of blood could be produced. The ability of compression of the trunk in man to cause extravasation is probably due to the peculiar arrangement of the veins and to their not possessing sufficient valves. [O.R.W.]

22.—Enderlen has carried out a series of experiments on dogs as to the possibility of **covering in defects of the bladder** with transplanted portions of the intestinal wall or of enlarging the size of the bladder by making an anastomosis between the bladder and an isolated portion of intestine. He sums up his article with the following conclusions: 1. In both the transplanting of a portion of intestinal wall and the forming of an anastomosis between the bladder and an isolated piece of the intestine the two kinds of epithelium retain their identity. 2. The epithelium of the bladder can grow for a short distance over the intestine in either the transplanting or anastomotic operation. 3. The intestinal wall at times shows slight atrophic changes. 4. The intestinal epithelium not only remains existent but also retains its functional activity. 5. The operation of transplanting a flap of the intestinal wall over defects of the bladder has in actual practice a very limited use and the same may be said as regards the forming of an anastomosis between the bladder and a portion of gut which has been isolated from the continuity of the intestinal tract. 6. The infection of the kidneys as a consequence of these operations is regarded as quite a possible happening. [G.B.W.]

23.—Kaiser reports an interesting case of **volvulus found in an inguinal hernia**. The patient was a man of 49, who for some years had had a large right-sided scrotal hernia but which had been held in place by a truss and had always been easily reduced. During a hard muscular strain the hernia was forced out and could not be replaced; accompanying this there was sharp pain and vomiting. Operation was performed early the next day. The hernial sac was filled with foul-smelling, cloudy yellowish fluid and the intestine was greatly distended and of a dark blue color and had lost its usual shiny appearance. Both large and small intestine were found in the sac. After enlarging the first incision upward and carefully examining the relation of the different parts contained in the hernia it was seen that the small intestine which was an occupant of the hernial sac was a con-

tinuance of a loop lying in the abdominal cavity which was markedly distended and discolored and whose mesentery was twisted into a funnel-shaped figure constricting the supplying bloodvessels. The large intestine was also found to be twisted on its long axis for some 180 degrees, but the torsion was not sufficiently tight to hinder the supply of blood. The incarceration of the large gut was caused by the constriction at the hernial opening and the ring-formed mark of the constriction was situated just distal to the ileocecal valve. The various twists of the intestine were unwound and the gut placed in the abdominal cavity without further handling. The patient sank rapidly after the operation and died in about 12 hours. The postmortem showed an exceedingly long mesocolon which would readily allow of torsion of the gut. [G.B.W.]

24.—Lanz reports a case of **tuberculous disease of the epididymis** in which an attempt was made to remove the epididymis alone and leave the testicle in situ. After removal of the epididymis, the testicle, as far as one could determine, seemed without disease, but to be sure, the organ was cut open longitudinally for its whole extent. Unfortunately the testicle was then found to contain numerous tubercular foci so that it was necessary to remove it as well as the epididymis. Lanz, however, believes that there are cases in which this particular operation would be very applicable, and the method of splitting the testicle furnishes sufficient insight into the organ to determine the exact condition. [G.B.W.]

25.—See editorial columns.

26.—Tavel in his research over **vioform** made a series of experiments with vioform, loretin and iodoform, to determine their comparative value as germicides. The results showed that vioform had the greatest power to stop the growth of bacteria and is therefore the best antiseptic powder of the three. Experiments showing the power to kill directly living germs were satisfactory and not conclusive. Toxicological experiments showed that vioform could be injected in large doses subcutaneously without causing any general symptoms. Locally, after large doses permanent swellings were formed, sometimes abscesses which, however, were always sterile showing the chemotactic action of the drug. Practically vioform because of its being nonpoisonous, non-irritating and odorless is a useful antiseptic powder, but its greatest utility lies in the fact that it is not easily destroyed by the action of other drugs, and can therefore be used as a medium for the application of carbolic acid, lysol and other like remedies. [G.B.W.]

27.—Becker reports 3 cases of **osteomyelitis** complicated by tumor-like formations due to the development of connective tissue around isolated sequestrums. The important feature of these cases was the making of a diagnosis between the condition present and sarcoma. In two of the cases this was fairly easy, due to the mobility of the tumor, the lack of pain, and emaciation. In the third case, however, the diagnosis of sarcoma was seemingly justified by both the clinical picture and the pathologic findings of the mass after its removal. In the other two cases the examination of the specimen obtained by the operation demonstrated the existence of a central cavity, containing an isolated sequestrum and communicating by a strand of granulation tissue with the internal condyle of the femur. In all of the cases the microscopic appearances of the granulating tissue forming the mass of the tumor, resembled almost exactly that of round cell and spindle cell sarcoma. [G.B.W.]

28.—The case of **gastric hemorrhage following cholecystectomy**, reported by Schmidt, occurred in a woman of 58. The cholecystectomy was done for supposed dilation of the stomach from stenosis of the pylorus, probably of a benign nature. On opening the abdomen, however, the stomach and pylorus were found to be perfectly normal, and instead the gallbladder was felt greatly distended and filled with stones. The bladder was attached to the liver, omentum, transverse colon, and pylorus by a few light adhesions which were easily torn through; it was then opened and removed, and drainage carried down to the stump with closure of the greater part of the abdominal wound. On the fifth day after the operation the patient vomited a quantity of a blackish fluid (blood) and continued doing the same for 5 or 6 days. Also numerous stools were passed, markedly tinged with blood, but the condition finally cleared up and the patient made a most excellent recovery. A possible expla-

nation of the etiology of the hematemesis is that during the operation some manipulation of the pylorus or the tearing and ligaturing of the adhesions led to postoperative ulceration of the stomach or pylorus. [G.B.W.]

1.—Hohlbeck reports 3 cases of **Meckel's diverticulum** causing intestinal obstruction. The first is a lad, 18 years old. Three days before his admittance to the hospital he developed signs of acute intestinal obstruction and when operated on an ileocecal intussusception $\frac{1}{2}$ foot in length was found. The intussusception was easily reduced when a diverticulum about the size of a walnut was seen. The patient died a day or two after the operation. The second was a child, $4\frac{1}{2}$ years old, who had suffered often with intestinal complaints. The patient was suddenly seized with abdominal symptoms which led to the diagnosis of intestinal obstruction from a Meckel's diverticulum. The operation confirmed the diagnosis. A portion of intestine 27 cm. in length was removed with the diverticulum and the abdomen closed with drainage, but the child died the following night from shock. The last patient was a married woman 39 years of age. She had never had any gastric or intestinal disturbances until 3 days ago when she developed symptoms of intestinal obstruction. At the operation a diverticulum 23 cm. in length was found causing occlusion of the gut. The intestine peripheral to the diverticulum was dilated and markedly injected so that 80 cm. had to be resected. The abdomen was closed except for an iodoform gauze drain. The patient made a good recovery. [G.B.W.]

2.—Janni says that in **varicose veins** besides the retrograde changes caused by the passive dilation of the walls, there is occasionally a new formation of connective tissue. This later is found chiefly in the intima and appears in the form of a nodular or plate-like endophlebitis. In these endophlebitic areas there is a necrosis of the inner elastic membrane which is occasionally accompanied by a marked new formation of elastic fibers. At the places where the nodes and plates have formed there is often a limiting layer of newly formed connective tissue in the innermost part of the media. This endophlebitis is a primary lesion, and is not a compensatory condition following some other disease. [G.B.W.]

3.—Capurro has carried out a series of experiments on dogs to determine the value of **transplanting flaps of muscle**. His results are as follows: The transplanting of unattached flaps of striated muscle, whether in animals of the same or different species, gives negative results, no matter what the method of operating is. The muscle thus transplanted, in the majority of cases, is destroyed by an ischemic necrosis, but in some there is a gradual metamorphosis of the muscular fibers into connective tissue. The plastic transplantation of pedicled flaps accomplishes two purposes, the mechanical strengthening of the part and the restoration of the normal functional movements. The contractability

of the flap depends upon the method of transplantation. 1. It is greater, when other conditions are equal, in the partial flaps than when the whole muscle had been used, in flaps of moderate tension than when tightly stretched, in flaps which are attached to muscles running parallel and in the near neighborhood of the muscle from which the flap was raised than when fastened to distant and nonparallel muscles. 2. It is greater the acuter the angle at which the flap stands from its mother muscle, and in simple twisting and bending of the pedicle. 3. It is greater when a portion of the covering aponeurosis is transplanted with the muscle than when only the muscle tissue itself is transplanted. 4. It is markedly reduced by laxness of the flap, by marked tension, by transplantation into yielding tissue without autochthonous movement. 5. It is not perceptibly influenced by the position of the pedicle, by the antagonism or synergy of the receptive to the mother muscle, or by the relation of the aponeurosis or sheath of the primitive muscle. [G.B.W.]

4.—Schanz reports a case of spondylitis following typhoid fever occurring in a woman 36 years old. By treatment with plaster-of-paris and leather corsets she finally made a good recovery. He goes on to say that though the symptoms of *spondylitis typhosa* vary a great deal, the cases generally tend towards recovery. This disease often resembles tubercular spondylitis very closely and is to be distinguished by the acuteness of the onset and the sudden development of pain and tenderness. Also in the typhoid spine there is very apt to be an inflammatory edema over the diseased vertebra and other neighboring foci. The Widal's test generally gives a positive reaction. The treatment consists in the application of plaster-of-paris casts and supporting corsets. [G.B.W.]

5.—Schanz says that in very favorable cases, good external cosmetic results can be obtained in *scoliosis* with the portable apparatus, but that treatment with the stationary supporting apparatus when the proper care is exercised is in suitable cases a perfectly rational method of handling these patients. But one must always remember that if a lasting cure is to be obtained it is necessary to correct the cause rather than the deformity. [G.B.W.]

6.—Aue reports a case of *tracheal defect* following the swallowing of a mouthful of boiling water some 12 years previous. The deformity consisted of an opening in the anterior wall of the trachea measuring 5 cm. long and from 2 to 3 cm. broad and in marked stenosis of the larynx and trachea from the abundance of connective-tissue formation. The operation for remedying this unfortunate state of affairs consisted first in the removal of the connective-tissue and the covering of the raw surface with a flap of skin taken from the neck. The anterior wall was formed by an osteocutaneous flap possessing skin on both surfaces of the bony portion. It was made as follows: A vertical incision was made along the left edge of the sternum for 3 cm. and another run across the sternum at right angles from the original one for 6 cm. A piece of the anterior surface of the sternum was chiselled free and the skin-flap was folded over it so as to surround both sides of the bone. After healing had taken place this osteocutaneous flap was freed and after freshening the edges was stitched over the tracheal defect. At a third operation the raw surface on the sternum was covered in and the final result was most satisfactory. [G.B.W.]

7.—Sierlin was only able to collect 4 cases of *fracture of the base of the skull* with paralysis of the ninth to the twelfth cranial nerves. His own case is as follows: The patient, a man 58 years of age, fell from a height on his head, but was soon able to get up and walk to the house. Immediately after the accident he was unable to speak plainly, had difficulty in swallowing, and saw double towards the left. His condition on examination was: Paralysis of the left external rectus muscle due to involvement of the left abducent nerve, paralysis of the right half of the tongue from involvement of the right hypoglossal nerve, paralysis of the right half of the soft palate, marked paresis of a right vocal cord, involvement of the recurrent laryngeal, paresis of the right constrictor of the pharynx supplied by the descendens hypoglossi, and irritation of the right spinal accessory nerve. Seven weeks after the accident the patient died and at the postmortem a fracture of the base of the cranium extending obliquely from the frontal bone to the foramen magnum was found, and the presence of bony callus causing pressure on glossopharyngeal and hypoglossal nerves. [G.B.W.]

8.—Rammstedt has collected from literature 12 cases of *ossification of muscle-tissue* following traumatism, but in which no fracture has existed. Besides these he gives in detail 2 cases which have come under his own jurisdiction. The first of his own cases was an ossification of the vastus internus of the left thigh in consequence of a kick from a horse some 3 weeks earlier. The greater part of the bony deposit was removed and the function of the leg was completely restored. The second case was much the same except that besides the bony deposit a cyst had developed, evidently as the result of a large extravasation of blood from rupture of a branch of the profunda artery. The result in this case was that after the lapse of 6 months or more there was normal motion both in extending and flexing the knee-joint. Of the whole 14 cases reported, in 11 the vastus femoris was affected and the triceps brachii, the brachialis internus and the gluteus maximus each once. In all of the 14 the trauma was the result of some severe direct force, in 9 cases horse kick, and the following ossification took place within from 19 days to 7 weeks. The osseous tissue was intimately connected with the muscle and consisted of more or less compact spongy bone. A careful study of all these cases demonstrates that at different times repeated hemorrhages had taken place in the various muscular layers, and that each of these hemorrhages was followed by a new formation of bone. Also that the hemorrhage within the muscle, the following proliferation of connective tissue and the further metaplasia into bone and cartilage held one to the other an inseparable etiological connection. Therefore taking also into consideration the form and position of the bony deposit it must be accepted that the formation of bone does not come from the periosteum, but is of intramuscular origin. The treatment should always consist in the removal of the ossified muscle. [G.B.W.]

9.—Smits has had in his own experience, during the past 8 years, 22 cases of *abscess of the liver*. Of these one was not recognized until the postmortem. All the others were operated on, with 3 deaths and 18 recoveries, and in the cases which died the necropsy showed the presence of multiple abscesses which had not been diagnosed during life. In all the cases there was only one woman and the greater majority were of the Caucasian race. Eleven of the abscesses were caused by malaria and 4 by dysentery. The first principle in the surgical treatment of these cases is, as soon as the presence of the abscess is suspected, it must be located and as soon as this is done free drainage must be established. The diagnosis is based on the presence of tenderness in the hepatic region causing disturbed respiration and on the variations of inflammatory fever, especially when physical examination proves the absence of disease within the chest itself. Some cases are easily recognized while in others a diagnosis seems almost impossible. Swelling over the region of the liver is a very changeable sign and sometimes when there is great bulging the pus may lay very deeply. Palpation often gives important data as to the size of the organ, especially in regards to the lower border, but percussion alone will allow one to recognize the level of the upper limit of the liver, and this latter is of far greater importance as far as hepatic abscess is concerned. Pain and tenderness over the liver is an almost constant symptom, and pain over the scapula is quite pathognomonic of lesions of the liver. Though fever is generally an early accompaniment of the disease there are cases which have died without any rise of temperature having taken place. The fever is usually of a hectic type, though in the so called tropical abscesses it may resemble closely that of malaria. Cough shows that there is extension to the pleura or involvement of the lung itself, and when perforation into the lung has really taken place putrid expectoration may be present. Exploratory puncture will remove all doubts when once the pus has been found thereby. It should be done with a large needle of some 2 or 3 mm. diameter, which may be inserted in almost every direction, even through the pleura or lung itself. The dangers of this puncturing are sepsis, hemorrhage, and the injuring of some neighboring organ such as the gallbladder or colon. The abscess may be treated either by drainage through a large puncture opening made with trocar and canula or by an open incision. Smits employed the open incision in the following manner: An incision is made over the prominence of the liver and a strip of gauze introduced between the parietal and visceral peritoneum and left in

place for six days. This produces adhesions which prevent the pus when it is being evacuated from getting into the abdominal cavity. The opening of the abscess is accomplished by locating its position with the exploring needle and incising with the cautery. A large drainage-tube is then introduced and the wound dressed. [G.B.W.]

10.—Pichler says that the sacral method of operating on carcinoma of the rectum possesses the advantages of a more open approach, the possibility of an easier and more exact checking of the hemorrhage, the establishing of a better drainage and the more radical removal of the disease. He reviews the statistics which have been reported by the leading German surgeons and adds 119 cases operated on by Professor Hochenegg. Of these 119 cases 72 were men and 47 women and they ranged in age from 21 to 72 years. The contraindications to operation are metastasis, marked cachexia and firm fixation of the tumor in the pelvis from an extension of the disease. In all of the 119 cases the method of operating was practically the same, differing slightly in individual cases, depending on the size and extent of the disease. Since the last three years the section of the sacrum has been made in the shape of an arch with the convexity upwards, thus saving the tuberosacral ligaments. The results obtained show: 10 deaths immediately following the operation, 14 cases from which no report of their subsequent history could be obtained, 40 deaths from return of the disease with or without metastasis, of which 5 took place after three years had elapsed after the operation, 8 cases died from other disease than the return of the cancer, 15 have not been heard from as to the final result, and 32 are living today well and strong. Of these latter there are three which have not yet passed the 3-years limit. As to the local result, there were 34 cases of complete control over the bowel, 77 were left with an anus sacralis and 8 possessed an anus in the normal position but without a sphincter. [G.B.W.]

11.—Noesske says that since 1896 it has been recognized that the color production of the *Bacillus pyocyaneus* is not increased by a rapid growth of the microorganism, but is proportionally less as the speed increases with which the germ develops. The color is probably due to the production of the various salts of sulphur and magnesium. The blue coloring-material of the *Bacillus pyocyaneus* is characterized by its nonsolubility in water and alcohol and its solubility in chloroform and it consists chiefly of a leukobase. But further research is required both quantitatively as well as qualitatively before our knowledge of the color production of this microorganism will be at all complete. [G.B.W.]

1.—Starck contributes the first part of an article upon a particular form of **esophageal diverticulum**, that is practically a critical summary of the literature upon this subject. He defines the condition as a sac-like extrusion of the posterior or lateral wall of the esophagus just where it touches the pharynx, which has arisen either as a result of a continual internal pressure or has been developed as a result of this internal pressure. Several theories of its course have been suggested. It was supposed that it could arise as a result of some persistent defect in development. This theory seems to find little support from the congenital anomalies of

the esophagus, and many of the ideas upon which it was based have been shown to be also. It was also supposed to be due to imperfect closure of the branchial clefts, but the diverticula are not found in situations where the fistulas resulting from this defect ordinarily occur. Albrecht has suggested that it represents the return to a primitive type, that is the type of a pig, camel, or elephant; but as a matter of fact, the *aditus esophagus* is not found in the same situation as the diverticulum. Zenker believes that they are due to the internal pressure upon some weakened area in the wall, and Starck suggests that this weakening may be due to some injury to the esophagus during deglutition producing a tear not only in the mucous membranes but in the muscular wall; the tear in the muscle-wall remaining unhealed. He also believes that there is sometimes a congenital weakening in the muscle at the point where the pharynx joins the esophagus. In this weakened area, pouching may occur which subsequently may result in a diverticulum. A point in favor of the congenital theory would be the occurrence of a complete muscular sac. This has not been found certainly in a single case as yet. In conclusion, Starck reiterates that there is no foundation for the belief of the congenital origin of this diverticulum, it may result from wounds or from congenital weakness in the muscles. [J.S.]

2.—Brosch gives a classification and discusses the various forms of **diverticula of the esophagus**. He considers first the **pulsion-diverticulum**. It does not seem certain that injury to the muscle-wall can produce this. He gives in tabulated form all cases of this condition hitherto reported. He does not consider the existence of a muscle-layer as an essential for the belief that these forms of diverticula are congenital. They may occur in any portion of the esophagus, and usually possess a more or less perfectly formed muscular layer. When, however, there is no muscular layer, we speak of the condition as **esophagocoele**. As a result of the consideration of this and other forms, Brosch gives the following classification:

- A. True diverticulum.
 - No. 1. Pulsion.
 - (a) complete with all the walls.
 - (b) esophageal consisting only of mucous membrane.
 - No. 2. Traction-diverticulum.
 - (a) simple.
 - (b) combined, probably the result of perforation by a gland or by an abscess.
- B. Mixed forms.
 - No. 1. Traction pulsion-diverticulum.
 - No. 2. Traction-diverticulum.
- C. Pseudo-diverticulum.
 - No. 1. Completely formed with fibrous wall.
 - No. 2. Pathologic varieties, such as abscesses, cyst, etc.

The results of these various forms differ. Pulsion diverticula have a tendency to enlarge. The traction-diverticula, and even the deep-seated pulsion-diverticula often continue without symptoms. The pseudo-diverticula when completely formed are rather a discomfort than a dangerous condition. The differential diagnostic point between the pulsion and the pseudo-diverticula is the ability in the former under certain conditions to regurgitate the accumulation of food. [J.S.]

3.—His has continued the experiments of Freudweiler on the **introduction of uric acid or urates into the body**. He has prepared some crystals of acid sodium urate and injected quantities varying from $\frac{1}{2}$ to 1 gram into the perineal cavity and into the joint cavities. Apparently, though, an intense local reaction was produced, the animals suffered from no discomfort. The necrosis produced by the injection differs from that produced by ordinary foreign bodies in that it commences earlier and reaches a greater intensity and extension, and even involves neighboring parts. Therefore, the substance acts partly as a foreign body and partly as a weak tissue-poison. If the salt is injected in amorphous forms it sometimes crystallizes, but at any events it is absorbed by the mucous membranes in the course of 8 or 10 days. It is probable that in acute human gout, the same course of events occurs. In chronic gout, however, the ability to react is diminished. Therefore, in the treatment of gout it is important to consider not only the chemical but the vital condition of the patient. [J.S.]

4.—Jünger has made some careful investigations of the blood in order to determine the **nature and frequency of the nuclei present in the red blood-corpuscles**. He stained his preparations first in picric acid and then in very weak hematoxylin and eosin. In the blood from a case

of leukemia, he was able to study all the processes of division of these cells which apparently take place by karyokinesis. The technical description of the nuclei in the various stages cannot be given, but Jünger believes that in general the process has no characteristic peculiarities. The fate of the nucleus appears to be somewhat as follows: There is first a shrinking with increased tinctibility, the nucleus then assumes a peripheral position, it may break up into small parts that may be either separated or united, there is then a moderate karyolysis and finally it disappears completely. [J.s.]

5.—Hönig reports an interesting case of a man of 55 years of age who 7 years before had had luetic infection, and who was in the habit of consuming large quantities of alcohol every day. He suddenly felt a severe tingling in both feet, the lower extremities then became cold, very weak, and occasionally severe pains were felt in the muscles. The gait was markedly affected, and finally it was only possible for him to walk by the aid of a cane. Then paresthesia developed in the upper extremities associated with severe pain particularly at night. There were no disturbances in the functions of the cranial nerves; the fingers were spread and continuously extended, but the muscle-power was well preserved. There was pronounced ataxia in the movements of both the upper and lower extremities. Touch, pain, and temperature-sense were preserved. The localization-sense and the muscle-sense were almost completely lost. All the reflexes were preserved excepting the plantar and patellar reflexes. The functions of the sphincters could not be compared. There was slight atrophy with partial reaction of degeneration in the muscles of the hand. A diagnosis was made of **alcoholic polyneuritis simulating locomotor ataxia**. As a result of the withdrawal of alcohol, the patient rapidly recovered and was able subsequently to return to his occupation. In discussing the literature of this condition Hönig calls attention to the fact that in cases of long standing, alterations are found in the spinal cord, and that the condition, therefore, cannot be reckoned to the pure peripheral nervous diseases, but the symptoms must be considered in part due to the associated central alterations. [J.s.]

6.—Stæhelin has made a series of observations upon 12 patients convalescing from **typhoid fever**, in order to determine to what extent **muscular exercise** affected their hearts. The patients were obliged to do a certain definite amount of work—that is, to raise their own bodies, like climbing stairs, a certain distance in a given time, and the pulse was counted before and after the exercise. The increase in its rate was very considerable, sometimes amounting to as much as 30 or 40 pulsations in a minute. It was found to be greater in those cases in which the disease had been very severe, and particularly in women. Careful study made in order to determine the rapidity with which the heart returned to the normal showed that it did so very much more slowly in these cases than in normal persons, and sometimes as long as half an hour after the exercise it was still elevated. When the exertion was repeated, it was found that the ability to recover diminished considerably, and Stæhelin believes that we should be exceedingly careful in avoiding all exercise or any form of work in these cases. Eight patients convalescing from pneumonia were also tested in this manner, and it was found that the increase in the pulse-rate was not nearly as great. Sometimes, in fact, there was decrease within 2 minutes after the exertion had ceased. This slowing of the rate was often followed by a subsequent increase. A number of studies were made with the sphygmomanometer, and it was found in the cases of typhoid fever that frequently after exertion a **dicrotic pulse** appeared. In the cases of pneumonia there was distinct evidence, even during rest, of diminished arterial tension, and occasionally dicrotic pulse was observed. [J.s.]

7.—Schiff reports a case of **typhoid fever** occurring in a boy of 19, who was admitted to the hospital suffering from a moderate attack which proceeded normally until the patient suddenly developed incontinence of feces. Then there was complete **paralysis of both lower extremities**, and nearly complete paralysis of both upper extremities. There was also complete anesthesia for all forms of sensation bounded sharply by a horizontal line anteriorly at the level of the third rib and posteriorly at the level of the second dorsal spinous process. Above this point the patient had normal sensation and the muscles of the face were not involved. There was evidently extreme

dyspnea. At each respiration the abdomen was strongly protruded and the lower borders of the thorax contracted indicating purely diaphragmatic breathing without a fixation of the thoracic wall. Death occurred 18 hours after the onset of the symptoms. A diagnosis was made of **transverse myelitis** whose upper border reached the level of the junction of the fourth and fifth cervical segments. At the autopsy the spinal cord on the level of the fourth, fifth and sixth cervical segments was swollen, reddened, and soft. Microscopically, minute hemorrhages were found in the substance of the cord throughout all the cervical region, and at the level of the fourth cervical segment there were some alterations in the ganglion-cells of the anterior cornua. The axis-cylinders of the fibers in the posterior columns were greatly swollen and there was apparently some degeneration. Below this point the bloodvessels were enormously dilated and hemorrhages were found everywhere throughout the tissues, and it was impossible to recognize structure of the spinal cord. In the first dorsal segment the spinal cord appeared to be perfectly normal, but there was another area of disseminated hemorrhages in the fifth cervical segment. Cultures and stained preparations failed to reveal the presence of any form of microorganisms. Schiff considers the condition in the cervical cord as a sort of hemorrhagic infarct. He believes as a result of the absence of microorganisms that the exciting cause was the toxin of the typhoid fever, and he therefore considers the case an evidence of the occurrence of the toxic form of myelitis in the course of infectious disease. [J.s.]

8.—Neumayer has undertaken to determine the **accuracy of Trommer's test when creatinin is present in the urine**. He found that meat-extract substances changed the copper solution into a bright yellow opaque fluid. This bright yellow color also occurred in a solution of creatinin and dextrose. Neumayer discovered that by the addition of an alkali to the solution, this light yellow color-precipitate was prevented, and in its place the characteristic reddish copper oxydul precipitate occurred. [J.s.]

1. Vaccinia and Variola in the Course of Pregnancy. CH. VINAY. (*Gaz. Heb. de Méd. et de Chirur.*, May 3, 1900. 47me Année, No. 35)
2. Gigantism and Diabetes. CH. ACHARD and W. LOEPER. (*Gaz. Heb. de Méd. et de Chirur.*, May 10, 1900. 47me Année, No. 37.)

1.—Vinay advises **vaccination of a pregnant woman** whenever there is danger of her becoming exposed to small-pox infection. The operation should be done under strict aseptic precautions. A pregnant woman should not be vaccinated on the leg on account of the liability to inflamed lymph-nodes or a lymphangitis near the uterus as a sequel. Vaccination of pregnant women often results in protection of the fetus both from vaccinia and variola. Pregnant women, furthermore, are prone to contract severe forms of infectious diseases, hence another reason for vaccinating this class of patients. The author considers the aggravation of the infectious diseases during gestation to be due to the autointoxication of pregnancy. [J.M.S.]

2.—The authors report the case of a man, aged 31 years, who was a giant. The **gigantism** was hereditary in the paternal line. There were symptoms of **akromegaly**; the chin was a little prominent and pointed; the cheeks were prominent and gave the face a size disproportionate to that of the forehead; the occipital protuberance was markedly prominent; the sternal angle and the insertion of the first rib were very pronounced; and the hand was relatively more developed than the other segments of the upper extremity. These defects of proportion coexisted with other features that were not akromegalic in character, such as increased length of the thigh in relation to the leg. The ordinary signs of akromegaly were wanting, such as ocular troubles and cephalalgia. There were no signs of enlargement of the pituitary body, which enlargement may also be present in gigantism. Glycosuria, which was present in this case, was subject to sharp oscillations. It has also been observed in cases of akromegaly. [J.M.S.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Treatment of Syphilis.—According to *Treatment*, June, 1900, Mr. Jonathan Hutchinson gave his latest views on this subject in a recent lecture at the Polyclinic. He considered the disease to be milder than it was formerly. As regards mercury, although this was now the universal antidote, it was not absolutely essential, since syphilis might run its course and die out without treatment. Excision of the chancre might be effectual if done within a week or a fortnight after contagion, by rendering further symptoms milder, if not preventing them. The lecturer advised mercury to be given as soon as possible and before secondary symptoms had appeared. He was of the opinion that if mercury was begun from the fourth to fifth week after contagion, and continued long enough, no further symptoms occurred. He advised the continuous method of administration as opposed to the intermittent or the symptomatic methods. He did not think it mattered much in what way mercury was introduced into the system, but objected to both inunction and injection, on the grounds that the dose of mercury given in these ways was uncontrollable. His method was by internal administration of 1 grain of gray powder in pills three times a day for a week, then four times a day, and after a fortnight five times a day. The mercury was combined with $\frac{1}{4}$ grain of opium. This treatment should be continued for a year. He often gave, in addition, iron and quinin in a mixture. Iodids should be given separately, and not combined with mercury.

Cooper has recently given his views on the subject (*West London Medical Journal*, April, 1900). He differs from Hutchinson in placing no reliance either in excising the indurated sore or attempting to destroy it by the cautery, holding the view that the induration is a local manifestation of constitutional infection. He advises black-wash, or equal parts of mercurial ointment and vaseline, as local applications to primary sores. He insists on the avoidance of mercury in phagedenic sores, and on the treatment of this condition by the hot bath. He does not agree with Gowers that syphilis is incurable, but says that it is often difficult to tell when a patient is cured. Cooper prefers internal administration of mercury, and recommends the tannate of mercury. This preparation is not acted on by the gastric juice, but passes unchanged into the duodenum, where it is acted upon by the alkaline secretions. Its advantages are: 1. It does not derange the stomach so much as other preparations, and in most cases does not irritate the intestines. 2. It is quickly absorbed and eliminated. 3. It does not produce stomatitis so much as other mercurial preparations, and, since it has no cumulative properties, it can be left off directly the gums show signs of soreness. It can be given in doses of 1 or 2 grains in a pill thrice daily. Cooper also recommends inunction, and also intramuscular injections of sozoiodol of mercury, $\frac{1}{2}$ grain once a week. He advises a 2-years course of mercury.

Therapeutics of the Nitrites.—Parker (*Physician and Surgeon*, May, 1900) states that the usual custom of administering amyl nitrite by the inhalation of the vapor of 2 or 3 minims of the drug, is in every way satisfactory. With the ordinary methods of administering nitroglycerin, however, fault can be found. Practically everybody says begin with $\frac{1}{100}$ of a grain of this drug and increase this gradually as may be necessary to get the desired effect. Now, in the experience of the writer one-half this dose has over and over again relieved the cardiac asthma, or other condition for which it was prescribed, and with almost complete avoidance of the headache and other disagreeable symptoms. Physicians have reported satisfactory results from the use of nitroglycerin in doses of $\frac{1}{100}$ of a grain. Besides securing satisfactory results without disagreeable symptoms, there is another reason why the beginning dose of nitroglycerin should be small. Tolerance of the drug comes on quite rapidly, and so when it has to be given for a long time, as in arteriosclerosis, the smaller the beginning dose the greater the chance to increase it, and still to keep within reasonable limits. Another feature in the administration of the nitrites with which the writer feels he can find fault, is the common custom of combining in a pill or tablet nitroglycerin with

digitalis, and other heart-tonics. This seems to be wholly unscientific and illogical. The effect of the nitrite comes on at once, and may have to be repeated in 2, 3, or 4 hours. The effect of the digitalis cannot be looked for until hours have passed by, and it cannot be repeated at frequent intervals. Again, the nitrite may be alone sufficient to correct the trouble. If it will do so, the physician has escaped the danger of having the digitalis do damage to the cerebral vessels, a danger always present when the arteries are in an atheromatous condition. If the physician can get along without the digitalis he can also get along with smaller doses of the nitrite, for the reason that digitalis always exerts considerable influence in contracting the arteries.

Notes on Chloretone.—Rudolph (*Canadian Practitioner and Review*, June, 1900) publishes the results of an experimental investigation of the physiologic properties of this drug. While he has not specially investigated the local anesthetic effect of chloretone, several casual observations lead him to infer that it is far inferior to cocaine in this respect. In guinea-pigs in which intraperitoneal injections of the saturated warm aqueous solution had been made, the small parietal abdominal wound remained sensitive during the hours that the experiments lasted, although it had been freely bathed with the solution. The antiseptic power of the drug was not tested. It is difficult to test the hypnotic effect on animals, but undoubtedly a certain amount of drowsiness is produced with moderate doses, increasing as the dose is increased, to deep torpor. About .275 gram per kilo of body-weight produces in dogs a perfect anesthesia for experimental purposes. The pulse, respiration and blood-pressure remain good for hours, and the animal is completely insensible to pain, but it does not recover. After many hours, during which the body-temperature has been steadily falling, the pulse and respiration become very slow, the blood-pressure falls and the animal dies of heart-failure. If a dose, even insufficient to produce anesthesia, is given to a dog, the animal exhibits a considerable fall in body-temperature. He is drowsy, and when roused, staggers and falls, and this incoordination lasts for 2 or even 3 days. This last effect would be an objectionable one if the drug were used in medical practice for its general effect. The lowering of the body-temperature was a constant result of the drug's action. The author concludes that chloretone has little or no effect upon the pulse, respiration and blood-pressure for hours, but eventually, if the dose be large enough, these become depressed and the animal dies, the heart stopping before respiration. Chloretone has a profoundly depressing effect upon the body-temperature, lowering this more than any other drug, with the possible exception of alcohol. This depressing effect is evident before the animal is even drowsy, and is in ratio to the dose given. It may be partially prevented by keeping the animal very warm. Any drug which can exert such an effect upon the total heat of the body is one which requires to be used with great caution in medical practice. This is doubly important as the drug is very slowly got rid of, and we know of no antidote, with the exception, perhaps, of external warmth.

Cacodylic Acid.—Grassi (*Gazz. degli. osped.*, March 18, 1900) has studied the action of cacodylic acid in chlorosis and in tuberculous affections. The treatment was continued for long periods, and the drug was administered hypodermically. The strength of the solution was gradually increased, and the injections were given at first every other day and subsequently every day. The injections gave rise to no pain, and were never followed by the phenomena of intoxication. The treatment in chlorosis was always followed by an increase of weight, and by an increase in the elimination of urea, and a diminution in the quantity of urine. It is evident that arsenic decreases the oxidation of hydrocarbons and fats, and increases the decomposition of albuminoids. The drug does not affect the temperature of the body. In tuberculosis the action of the drug on the general condition is more marked than its local effect. Cacodylic acid increases the hemoglobin, but merely to the extent that it increases the number of red cells. Iron, on the other hand, has more effect on the hemoglobin than on the number of cells. The action of arsenic is therefore more cytoplasmic than hemoglobinoplastic. According to the author cacodylic acid, when introduced by the skin, is eliminated in the urine and not in the feces. It is recovered from the urine as cacodylic acid.

Original Articles.

A NEW METHOD FOR THE CLINICAL DETERMINATION OF THE POSITION OF THE CARDIA.*

By G. W. McCASKEY, A.M., M.D.,
of Fort Wayne, Ind.,

Professor of Clinical Medicine and Nervous Diseases in the Fort Wayne College of Medicine.

THE position of the cardia has received scant attention at the hands of investigators. The methods heretofore in vogue have, for the most part, assumed a more or less fixed and constant position for the upper border of the stomach, and have had for their object simply the delimitation of the lower border. This is especially true of Penzoldt's¹ method by the introduction of water and percussion, which, as Riegel remarks, has only to do with the lower border. The method of Punjesz² of introducing a manometer at the end of the tube, the sudden relaxation of pressure upon which indicated the moment of its entrance into the stomach, was exceptional in this regard. The method of Schreiber and that of Rosenbach dealt with inflated rubber bags in which respect they were similar to my own.

FIG. 1.—Cardiometer: for measuring the distance from incisors to cardia and also for defining absolutely the position of the latter with the aid of x-rays. A. Collapsed bag of thin rubber. B. Expanded bag after introduction into stomach. D. Closed bulb for inflating bag.

I have nothing to offer with reference to the determination of the lower border of the stomach, and will therefore limit myself not only to the upper border, but to the single point in it, known as the cardia.

With reference to its precise location, the statements made in current literature are decidedly and surprisingly conflicting. Morris³ says that it is opposite the ninth thoracic spine. Schäfer and Symington⁴ are responsible for the statement that it is at the level of the body of the tenth or eleventh dorsal vertebra; Hemmeter⁵ says that it is opposite the twelfth dorsal vertebra. Viewing it topographically from the ventral aspect, Einhorn⁶ says that it is in the left parasternal line, somewhat above the ensiform process; Van Valzah and Nisbet⁷ say that it is behind the cartilage of the seventh left rib. With reference to its relations to the

diaphragm Boas⁸ says that it lies two to three centimeters below the diaphragm; one author says an inch below the diaphragm, and another that the esophagus, after piercing the diaphragm, expands immediately into the stomach. Gegenbaur⁹ says that the position of the cardia varies with the growth and distention of the stomach and with the length of the esophagus; although in his illustrations he follows Luschka, and figures the cardia behind the seventh left costal cartilage.

It will be seen that the location of the cardia is fixed by different writers from the eighth to the twelfth dorsal vertebra. The explanation is perfectly obvious and is based upon anatomic variations in health and disease. The vertical position of the cardia must vary, as stated by Gegenbaur, with the length of the esophagus, which depends in health upon the embryologic development of the thoracic viscera, and chest-wall; and in addition to this in disease upon the traction of prolapsed viscera.

The question with which I was especially concerned at first was a purely clinical one, viz., the distance of the cardia from the incisors *per vias naturales*. In other words, to know when the stomach-tube or other intragastric instrument had reached or passed this orifice. Turning again to the literature, about the only statement that I could find was that of Van Valzah and Nisbet, that the distance from the incisors to the cardia was about 40 cm. We are even informed by them that the distance from the incisors to the cardia can be ascertained by measuring from the ninth dorsal vertebra along the spine and side of the neck to the front of the teeth. It is needless to comment upon the fallacy of such a method, in view of the data already given. In most cases, perhaps, the entrance of the tube could be approximately determined by the routine methods in vogue which were always inexact and unscientific, and sometimes, in my opinion, very objectionable and even dangerous. I refer especially to cases of severe gastric lesions, more particularly latent ulcer, in which it appears highly important to know how much rubber hose is contained within the stomach, and exactly when the end of the tube passes the cardiac orifice.

To furnish this information after trying various expedients I have adopted the following method, which gives results that I believe are entirely reliable:

In the distal end of a soft Goodrich colon tube I have placed a tightly fitting piece of metal tubing, over which was adjusted a small bag of very thin rubber, the end of which projects about an inch beyond the tube.

The proximal end was attached to a closed rubber bulb. Compression of the rubber bulb would expand the bag which would collapse when the bulb was relaxed. A centimeter scale was placed upon the tube measuring from the distal end, beginning at 30 cm. and extending to 60 cm. The tube with the rubber bag collapsed is introduced into the stomach and expanded by compression of the bulb. It is then withdrawn until the impact of the rubber balloon is felt against the cardiac orifice. The distance is then read off on the scale in centimeters with quiet breathing. This will show with absolute precision the distance of the cardia from the incisors with the respiratory muscles in the comparatively passive state of quiet breathing. The measurements which I have made have been limited for obvious reasons to patients, many of whom had gastroptosis. The results obtained in 12 cases, taken

* Read before the American Gastroenterological Association, Washington, D. C., May 1, 1900.

consecutively, are presented herewith in tabular form, in centimeters:

	Height of patient.	Distance from incisors to cardia.	Approx. comparative distance, incisors to cardia on basis of 175 cm. as height of each patient.
1.....	161	52	55.5
2.....	167	38	30
3.....	173	41	40.5
4.....	178	45	43.5
5.....	163	41	43.5
6.....	160	41	44.
7.....	168	42.5	43.25
8.....	168	51	52.
9.....	174	45	47.
10.....	169	41	41.5
11.....	175	46.5	45.75
12.....	176	45	44.

phragm are overbalanced by the stronger contraction of the abdominal muscles.

The information obtained in this way has been of great value to me in many cases. For instance, a patient was referred to me by a colleague (Dr. W. K. Mitchell, of Ligonier, Ind.), with a history of chronic indigestion, and recently severe pain after eating, and occasional tarry stools. There had been no vomiting. Upon examination, the characteristic tender points of gastric ulcer, both ventral and dorsal, were found to be present. The diagnosis of gastric ulcer was at once predicated upon these symptoms. I was extremely desirous, however, of securing the gastric juice for chemical analysis, and the washings from the fasting stomach for microscopic study.

The patient was of average height—175 cm., and the

FIG. 2.—Radiograph of case of extreme gastroptosis showing cardia several inches below the sternum. A and B. Lead wire placed on costal margin. C. Lower end of gladiolus. D. Stomach-tube. E. Metal olive tip, placed at cardia by previous measurement with cardiometer. F. Accidental blur on plate.

With reference to the measurements given in this table, it should be stated that in every case there was chronic gastric disease severe enough to lead the family physicians to refer the patients for special examination and treatment.

In addition to measuring the distance of the cardia from the incisors in a passive state, the respiratory movements of the former can be very easily demonstrated. Upon deep inspiration, the cardia is found to sink, on an average, about 2 cm. below, while on complete expiration it rises about 1 cm. above the position, which it occupies during quiet breathing. In the act of vomiting, furthermore, it is shown that the cardia rises, evidently because the contractions of the dia-

cardiometer was passed about 38 cm., and the bulb compressed. The resistance showed unmistakably that it was in the esophagus. It was then advanced 1 cm. at a time until the free expansion of the collapsed rubber-bag, as indicated by the disappearance of resistance in the bulb, demonstrated that the tube had entered the stomach. The distance of the cardia was then found in the manner already described to be 46.5 cm. A very soft graduated tube was then introduced, and by exercising great caution, withdrawing it when retching occurred, so that only 1 cm. or 2 cm. of tube projected into the stomach, irrigation was completed with no more important incident than the appearance of numerous bloody flakes of mucus obviously from the margin of

an ulcer. The complete diagnosis, which I cannot give here, furnished strong indications for local treatment, which was at once instituted with due precautions.

The patient was placed on full diet instead of emaciating and exhausting him by a starvation regime, and in three weeks had gained six pounds with corresponding improvement in general strength and symptoms.

In another case of profuse gastric hemorrhage, sent to me by my colleague, Dr. H. A. Deumling, I was encouraged by the precision with which I could use the tube to carry the case on to practical recovery as indicated by a gain of twenty pounds in weight and disappearance of hemorrhage.

With precise information concerning the distance of the incisors from the cardia it is possible in the course of simple lavage to make important and fairly reliable deductions with reference to the vertical measurements of the stomach. For instance, if the measurement shows that the cardia is just 45 cm. from the incisors and the tube has to be introduced 55 or 60 cm. before getting a continuous flow by siphonage, the conclusions are obvious. It is only in cases perhaps where there is marked atony of the stomach-wall that such data may be obtained. Where the stomach contracts actively upon the introduction of fluid the level of the latter would of course be raised far above the lower margin of the stomach in a passive condition. It has frequently happened, however, in my experience in cases of marked atony that the distance from the cardia to the upper level of the fluid as indicated by the continuous siphonage was so great as to positively indicate an exaggerated vertical measurement. With large quantities of fluid the possibility of error by reason of undue traction dragging down the cardia, must be kept in mind.

It is possible by means of this instrument to get some information regarding the caliber of the upper portion of the stomach in certain anomalous cases. For instance, in a recent case the measurements showed the cardia 43 cm. from the incisors. At a distance, however, of about 47 cm. from the incisors the inflated rubber balloon, which can be freely introduced into the deeper portion of the stomach, encountered a slight but marked resistance which was easily overcome until the solid impact against the cardia was distinctly felt, beyond which point it would not pass. This was repeated several times with uniform result. The possibility of diagnosing hourglass stomach in this way has occurred to me. In the case just referred to, the distance of the second resistance from the cardia was rather too small to be considered the contraction of an hourglass stomach besides which the passage of the rubber balloon between the two points gave the impression of a continuously narrow passage.

So far my investigations along these lines had been with exclusive reference to the precise distance of the cardia from the incisors with a special reference to the use of intragastric appliances. At this point it occurred to me that by fixing a piece of metal at the cardia and taking a radiograph with suitable surface landmarks made by the shadows of metal, the precise position of the cardia with reference to the surface of the body could be determined. This proved to be entirely feasible and I present herewith a radiogram demonstrating the result in a case of extreme ptosis. By this means at least one point in the upper border of the stomach can be mapped out on the surface with absolute precision.

CAUSE OF THE DECUSSATION OF THE NERVE-FIBERS
IN THE MEDULLA AND SPINAL CORD.

By D. T. SMITH, M.D.,
of Louisville Ky.

THE forces that have operated to produce the decussation of the axones in the medulla, or the ends that have been subserved thereby, have never been indicated in so far as I am aware, by any anatomist, either in the interest of teleology or evolution. The theory that is here proposed, or rather suggested by me, is not by any means conclusive to my mind, but it meets the logic of the condition to an extent sufficient to justify its setting forth as promisingly helpful to some more ingenious investigator who may have his mind directed to it.

If one attempts to scull a skiff on the water, he finds that the bow of the skiff turns in the same direction in which he moves the paddle of his oar. Again, if we watch fishes swimming in the water, the same character of movement will be observed to take place with them. The head of the fish turns in the same direction in which it moves its tail. If the tail is thrown to the right, the head turns to the right. If the tail is thrown to the left its head turns to the left. In the case of the skiff, the bow turns to the left when the paddle is moved to the left, because the reaction produced thereby pushes the stern to the right, forcing the body of the skiff to rotate on a pivotal point situated somewhere in advance of the stern. The principle involved in the turning of the fish is identical. When the fish's tail is moved, say to the left, some postpivotal point of the body must be moved in the opposite direction from that of the tail, or to the right, in order that the head shall move in the same direction as the tail. This pivotal point appears to be in the tail of the fish just posterior to the body, and embraces the thickest and heaviest part of the tail. The tail fin, with a small portion of the extremity of the tail, is moved in a given direction, and this throws the heaviest part of the tail, and possibly the posterior part of the body, in the opposite direction, and this, in turn, rotates the head in the same direction as the movement of the tail.

Pursuing this complex move a little further than is necessary to the purpose of our argument, we may observe that when the fish has bent its tail slightly, the web of the tail fin begins to slide off of an incline plane, formed of the water against which it presses, and this within certain limits, gives an increased intensity to the rotating movements, since it tends to push the thick part of the tail the more forcibly in the opposite direction.

But if the fish desires to make a rapid run, as it almost invariably does when it makes one of these sharp turns, it simply straightens out the tail, at the same time slightly relaxing the extremity and with it the tail fin. This enables it to go almost straight forward from this stroke; whereas, if the tail were straightened without relaxing the extremity of the tail, and

thus allowing the tail fin to bend, the fish would simply turn itself in the opposite direction instead of being driven nearly straight forward. This involves in an almost perfect way the principle of the turbine which is employed to propel the ocean steamer. Now in order to allow of the character of movement of the pivotal point in the fish just indicated, the muscles on the side or the sections to be thus made convex, must be relaxed, while at the same time those muscles which are to produce a concavity on the opposite side must be contracted. If now it so happened that all the muscles on each side of the fish's body had to be supplied with innervation by neurons on the same side, this would necessitate a situation more or less distant from each other for the respective motor centers controlling, for the time, the two antagonizing sets of muscles.

Therefore, since it is indispensable that the neurons controlling the muscles of the two sides of the body shall work in concert, a more or less extended route of communication would have to be traversed in order to admit of those on one side notifying those on the other of the motion they were about to inspire, and which required the inspiration of a coetaneous counter motion. It must have been then, of manifest advantage to the fish to have axones proceeding from each half of the brain to the muscles of both sides of its body. In this way neighboring neurons could act in quick concert in contracting the muscles on one side of the body, or in special regions of one side, and simultaneously relaxing those on the opposite side.

There is a necessity then, or at all events a distinct and obvious advantage secured to the fish or other such animal, in an arrangement by which part of the motor axones from the cortex pass out on the same side and a part pass onto the other side for distribution to the muscles of locomotion.

And this is what actually occurs. For, while the greater number of the motor fibers pass across at the decussation of the pyramids and make their way into the lateral columns of the opposite side of the cord, forming thus the lateral pyramidal tract, a small bundle of the outermost fibers of each pyramid runs downward in the anterior column of the same side and is known as the anterior pyramidal tract.

However, while there is a plain necessity for a division of the axones proceeding from each side of the brain, neither in the lower animals nor in the higher is it so apparent why the majority of the motor fibers should pass to the opposite side. If, however, for reasons that do not clearly appear, it so happened that in each case the fibers that passed down on the same side were to act as inhibitory fibers and those on the opposite side as contracting fibers, we can see a reason why the former should be gradually diminished, while the latter active contracting fibers increased in numbers in the progress of evolution. This would be the natural result of the requirements of innervation on the two sides. But let us suppose that the energy required to inspire contraction is greater than that required for inhibition of contraction or relaxation, and it will be readily apparent that it would be in the interest of economy for the greater force to take the longer route. If both sides of the body, as we have found, require to be innervated from practically the same center on each side, the one requiring a strong impulse and the other a weaker one, it would be to the advantage of the individual to have the weaker impulse traverse the shorter route, for in this way it could keep time with the

stronger impulse and they could both act in concert. This, then, would account for the fact that the larger proportion of axones pass over to the opposite side, provided these axones are tonic and not inhibitory.

It is highly reasonable to believe that there is a constant current of force, either electrical or capable of inducing electricity, moving along circuits formed by the axones of sensory and motor nerves, and possibly some other intervening tissue, and that this current is indispensable to the preservation of the vitality of the neurones and axones.

If this is true, it necessitates the crossing over of the axones of the sensory nerves in order that their extremities may meet those of the motor nerves, and thus complete the life-conserving circuits, or at least that the proportional distribution of motor and sensory axones shall be conserved whatever the nature of the requirements of that proportionment may be.

However, such a distribution would also meet the requirements of reflex action, since with such an arrangement stimuli acting on the terminal sensory axones could be reflected along the motor axones supplying the same parts.

When the higher order of animals was reached in the progress of evolution the advantage of this plan of nerve-distribution survived. In man it is especially appropriate. Thus, in walking, while the muscles on one side are on the whole being relaxed, those on the other side are on the whole being put to increased tension. It is true that the flexor muscles of the leg that is lifted in walking are made taut in doing so, but the strain on them is probably less, in so acting, than is that even of the corresponding muscles on the side of that leg which for the time supports the body. In the case of the quadrupeds intermediate between fishes and man, this double play of tension and relaxation is also favored by such divided innervation as is found in man and the fishes; probably even more so than in man, for the tendency to swing the arms as we walk may be but a vestige of the corresponding movement of the fore limbs in the lower animal. As a logical inference from the foregoing premises, we might look forward to the discovery of a subsidiary arrangement by reason of which the flexor and extensor muscles of each limb are controlled from common centers, as the same character of advantage would thereby accrue to the individual or the race.

How far down the scale of life the distribution of axones here considered obtains, I am without means of knowing. But if the cause here suggested is the true one, it ought to be found in the lowest animals that are possessed of a cerebrospinal nervous system, if not in all that accomplish locomotion by coordinate movements.

It is indeed a question whether the advantages of bilateral and reciprocal innervation in the effective accomplishment of locomotion, has not been the efficient cause or the determining guide that has resulted in the formation of two hemispheres for the brains of animals.

The exceptional magnitude of the brain in man is, however, most likely due to the fact that man has a larger extent of tactile body-surface than any other animal, notwithstanding the fact that paleontology reveals a progressive increase in the brain mass relative to that of the body in all known specimens of mammalia. In sight, hearing, smell and probably taste, man is surpassed by many animals, but none approaches him in the range of touch, which is the master

sense. And it is doubtless this sense possessed as it is in so exalted a degree, that by its reaction on the brain has caused its enormous development, and placed man so conspicuously at the head of the animal kingdom.

The Surgical Treatment of Congenital and Pathologic Disfigurements of the Face.

By JOHN B. ROBERTS, M.D.

Professor of Surgery in the Philadelphia Polyclinic.

LECTURE VIII.—*The Construction of New Noses.*

(Abstract.)

RHINOPLASTIC operations, for the construction of an entire nose or a portion of that organ, are required to repair the damages of syphilis and lupus and of intentional and accidental mutilations. American and Continental surgeons have very little experience with these operations, except in cases due to syphilis and lupus. English surgeons in India have very many patients with the cartilaginous portion of the nose cut off by sharp instruments. This mutilation is frequently adopted in India as a means of revenge. Keegan states that the number of such mutilations effected in a single year in India is unknown. That it must be large is evident from his statement that in the year 1897 there were 152 rhinoplastic operations performed in that country. In a single evening he saw, while riding through one of the native cities, as many as three or four women with mutilated noses, sitting near their huts. As a consequence of this distribution of rhinoplastic work, American and European surgeons have had much less experience than Indian surgeons. The cases seen outside of India are usually much more difficult to bring to a satisfactory conclusion by operation, because the tissues which remain have been distorted and altered by the syphilitic or tubercular ulceration which has destroyed the nose. In many of these nasal deficiencies, due to disease, the internal bony and cartilaginous structures have been entirely destroyed. In some instances even the nasal bones which support the nose at its bridge are also absent, as the result of the syphilitic necrosis.

Until recent years the technic of total rhinoplasty was somewhat imperfect; and, as a consequence, surgeons undertook the construction of a nose with considerable hesitation. More recent studies and the advantages of aseptic surgery have improved conditions to such an extent that these operations are now undertaken with much more certainty of obtaining an improvement in the patient's appearance. A very great deal can be done when only the soft parts of the external nose have been cut off. Quite a satisfactory gain is possible, even in cases greatly deformed by cicatricial contraction, subsequent to syphilitic ulceration of the hard and soft parts. In the latter cases the main difficulty is to get support to the flaps of skin which are used to make the new nose. Metallic supports and bridges of various sorts have been employed to hold up and give the requisite projection forwards of the flaps of skin which represent the new nose. In some cases these have been worn for a number of years and apparently with satisfaction. In others they have set up irritation, which has finally led to their removal.

Portions of bone have been chiseled, from the nasal bones and from the superior maxillary bones, and displaced in such a way as to hold the integument forward. These osteoplastic operations have been to a

FIG. 1.—Langenbeck and Ollier split the nose vertically, laid the soft parts to each side, and then sawed bony flaps from the edges of the nasal aperture above and below on each side. They then bent these bony flaps forward to give support to the frontal flap or the replaced soft structures.

certain extent satisfactory. Ollier, Koenig and Israel have made interesting suggestions in this connection. Sabine, of New York, constructed a new nose from a finger, which he attached to the sides of the chasm left by the loss of the nose. The finger-nail was removed and the palmar surface of the finger split so as to form lateral flaps. The hand was then applied to the face and the finger stitched to the edges of the nasal cavity. After circulatory connection was established, the finger was amputated from the hand through the first phalanx; and the end of the portion of finger, left attached to the face, was bent at the joint between the first and second phalanx, so as to make the end of the nose and its columella. A number of minor operations were subsequently done to improve the shape of the new nose.

The usual methods of rhinoplasty are the Italian, in which the tissues of the arm are attached to the stump of the nose; the French—sometimes called the German—method, in which the new organ is constructed from flaps taken from the cheeks; and the Indian method, in which the skin of the forehead is utilized in the nasal reconstruction.

FIG. 2.—Diagrams of Serre's method of rhinoplasty.

The Italian method was brought to the notice of surgeons in 1597 by the Latin treatise of Tagliacozzi. Before that time, however, rhinoplastic operations were performed by Sicilian operators. A brief reference is found, it is said, in a publication of Benedictus, dated 1497. Tagliacozzi's method was subsequently modified in various minor particulars, and is sometimes used at the present day. In fact, flaps are taken from the arm at times for reconstructing other portions of the face, such as the lips. Tagliacozzi himself speaks of this application of his method, and gives illustrations of it.

The brachial method, as it may be called, of Taglia-

cozzi, is tedious to the patient and requires a more or less complicated apparatus for holding the arm to the face during the time necessary for adhesion to take place. Hence, either the frontal method used in India from a very early time, or that in which flaps are taken from the cheeks, is more usually adopted.

FIG. 3.—Diagram showing Keegan's outline for the frontal flap in rhinoplasty. When the flap is rotated downward the point A is stitched at A' and B at B'.

Keegan has, as the result of his great experience in India, modified the usually described method of frontal rhinoplasty. He cuts a flap from the forehead, with its pedicle near the supraorbital notch of one eye, extending obliquely upward across the forehead. The upper border of the flap has a projection, from which he constructs the columella of the nose. He first makes a pattern of the flap by using a piece of banana leaf,

FIG. 4.—Diagram of Roberts's method of reconstructing a sunken-in nose. The dotted lines indicate the flaps taken from the cheeks to cover the opening into the nasal chambers left by the detachment and drawing downward of the cartilaginous nose.

which is flexible and supple. Having made this pattern, he cuts from stout brown paper an exact duplicate in shape. This is fixed to the forehead by an adhesive material, so as to render it easy to make a flap,

exactly satisfactory both as to size and shape. The soft tissues over the nasal bones are then converted into two flaps, which are turned downward upon a hinge, as it were, near the inferior border of the nasal bones. This maneuver puts the skin-surface of these flaps inwards towards the nasal cavity. The frontal flap is then cut and, by twisting its pedicle, it is carried downward so as to cover the denuded nasal bones and the raw surface of the turned-down tissues, which previously covered those bones. The columnar portion of the frontal flap is then properly sutured into a groove or bed at the upper part of the superior lip. Sutures are applied to close the frontal wound and fix the edges of the flaps in proper relation. Drainage-tubes are inserted in the newly-formed nostrils. The pedicle at the root of the frontal flap is divided at the end of about ten days.

The object in using the tissue covering the nasal bones to form the internal surface of the nostrils is to prevent contraction of the nostrils. These underlying flaps also give support and strength to the new nose, so that it is less likely to become flattened.

FIG. 5.—The cheek flaps sutured to close the opening.

Portions of noses may be constructed by various rhinoplastic procedures, but they need not be further discussed here. Some of them have been already mentioned in the previous lecture. The tissues of the lips and cheeks may be utilized for the formation of the necessary flaps, which are then displaced, so as to fill the gaps which are the cause of the nasal deformity.

The construction of a portion of the nose in cases of sinking-in, due to syphilitic destruction of the internal cartilaginous and bony supports, is often a difficult problem. In these cases the middle portion of the nose is greatly depressed and the tip of the nose turned upwards so that the nostrils look forward instead of downward. In some cases the nasal bones are destroyed, but they often remain uninvolved by the syphilitic necrosis. I have recently reconstructed such a nose in a very satisfactory manner by a combination of plastic procedures which is, so far as I know, new. The first step was to make a transverse incision in the hollow above the tip and alae of the nose, where the depression due to cicatricial contraction and want of support was the greatest. This enabled me to pull down the lower end of the nose and bring it forward so that the nostrils looked downward and the tip of the nose had its

normal projection forwards. This left a large opening between the cartilaginous nose and the lower end of the nasal bones. This space was covered by lateral flaps cut from the cheeks and turned inward towards the middle line with the skin surfaces towards the nasal chambers. These flaps should be cut in the line of the nasolabial furrow in order that the linear scar may correspond with this line more or less accurately and therefore be comparatively inconspicuous.

FIG. 6.—The dotted lines show the outlines of the two frontonasal flaps.

After these flaps had become united in this position, the irregularity due to the twisting of their pedicles was removed by a small plastic operation on each side. The next major step was to make two diverging incisions from the middle of the forehead, downwards and outwards, in the manner shown in the diagram. Two other incisions were made just above the granulating surface, situated at the point where the cheek-flaps had been united in the middle line. A median vertical

FIG. 7.—The frontonasal flaps sutured on top of the cheek flaps.

incision was made to connect the apices of the inverted V's made by these four incisions. The two flaps thus made over the nasal and frontal bones were then dissected from the underlying tissues and turned down-

ward so that the upper point of the right flap could be attached to the base of the left ala, and the uppermost point of the left flap turned over to the right side of the patient, so as to fit, against the other flap, below the inner canthus of the right eye. The wound left in the forehead was then closed vertically and numerous sutures applied to hold the displaced flaps in their new positions.

This maneuver covered the granulating surface of the cheek flaps that closed the opening in the nose; and gave thickness and solidity in the region where firmness is so essential, in order to maintain the outline of the organ. A number of minor operations were subsequently necessary to get rid of the irregularities produced by the coaptation of so many flaps, but a very satisfactory outcome has resulted. The new nose has a fair degree of prominence and the nostrils and alae are in proper position and of normal shape. The dorsum of the nose, while not beautiful, is free from the marked and disfiguring depression which formerly existed.

In order to make the prominence of the nose and upper lip relatively greater, a portion of the lower lip was removed by a V-shaped incision.

THE EARLY RECOGNITION OF ECTOPIC PREGNANCY.

By DEWITT G. WILCOX, M.D.,

of Buffalo, N. Y.

LIKE other of our recently recognized and better understood pathologic processes, ectopic pregnancy seems of more frequent occurrence than formerly. Whether due to a more accurate recognition, and hence only an apparent increase, or whether the increased frequency of salpingitis is responsible, we are as yet unable to determine.

Of this, however, we are certain: it is a condition which, from its inception to its close, is highly dangerous to both health and life. This danger is greatly increased because the condition gives so little warning of its presence, and the symptoms resulting are so out of proportion to the ever-present danger. Were the patient obliged to take to her bed from the first, because of pain or other symptoms, the danger would be greatly lessened, but the mere fact that she is on her feet and feeling fairly well, keeps the sword of Damocles over her head. A sudden exertion, lifting a piece of furniture, running up-stairs with a child in her arms, or straining at stool, may cause a rupture of the delicate membrane and the patient is dead before help can reach her, or if not so terrible an issue as that, she has started on a long road of invalidism from which she may never recover, save through the aid of the surgeon's knife.

With the details of a number of such cases before me, I am convinced that it is possible to recognize tubal pregnancy in its early stages, even as early as the fourth or fifth week, and before rupture of the tube. Indeed, if it is not recognized before rupture, the danger has been averted only in part.

It seems now settled beyond dispute that impregnation takes place in the tube near the uterine extremity. Bearing this in mind, also, that the ovum both impregnated and unimpregnated, is urged toward the uterus by the cilia lining the tube, and a mild contractive effort on the part of circular fibers, we readily see that

any factor acting as a bar to the ready progress of the ovum facilitates to that extent the possibility of tubal pregnancy. This bar may be an inflammation which has destroyed the cilia or created a partial stricture in the caliber of the tube, not sufficient to prevent the ready passage of the male element of fecundation, but sufficient to prevent the return passage of the fecundated ovum; or again, it may be that the caliber of the tube has been lessened by encroachments upon it from without, by tumors, adhesive bands formed by peritonitis, or torsion of the tubes. Every hour that this ovum is delayed lessens the possibility of its escape into the uterus, because it is steadily increasing in size.

Just what time is required for the passage of the fecundated ovum through the tube is not definitely known, but, according to the best authorities, this passage probably occupies not less than 8 days, and as the ovum has enlarged to about three times its original size, it must of necessity find its way into the uterus very soon thereafter or forever remain without.

It is a well known physiological fact that the uterus undergoes a certain preparation each month for the reception of the ovum. A few days prior to the arrival of the expected guest that organ "cleans house," and adds new interior furnishings; old shreds of membrane are cast off and a new heavy lining of a velvety character, richly supplied with blood-connections, is formed in the upper part of the uterine cavity; this is the decidua. If the ovum arrives as "guest-in-ordinary" (that is unimpregnated) then the new furnishings are torn down and cast off, and form part of the menstrual flow. If, however, the ovum comes as a royal guest (impregnated and developed up to six or eight days) then is the reception made befitting the guest. The doors and windows of the decidua are closed to prevent the untimely escape of the guest or intrusions from without. Richer blood-supply is added and the velvety hangings are materially increased in thickness. One corner of the reception hall is set aside for the guest, where it is permanently stationed and nourishment sumptuously provided. This guest, the ovum, sends out rootlets or villous growths, which ramify into the decidua, and the circulation between uterus and ovum is established.

It is a most entertaining sight to the scientist to watch the conduct of affairs when the host has been assured that a royal guest will soon arrive and the latter fails to keep the appointment. The ovum impregnated in the tube in the usual way, sends couriers announcing its early arrival in the uterus where the usual preparations take place. The eight days expire, but the guest does not appear; ten days and two weeks pass, yet he fails to come; the furnishings and hangings are wrought more elaborately as though that would hasten him. The uterine decidua has attained two or three times the size it would attain were it waiting an unimpregnated ovum; but at the end of four or perhaps five weeks, no guest has appeared and in disgust at such uncivil treatment, the host ruthlessly tears out all evidence of the elaborate preparations and casts them forth. The decidua has been expelled, and in this act we have one of the most positive signs of tubal pregnancy. This decidua may be the size of a placenta in a three months' uterine pregnancy, and the physician, if he is not alert, will be induced to think he is dealing with an ordinary abortion and may search long and carefully for a fetus which comes not.

We now go back to the ovum and see what sort of

treatment it has received at the hands of the tube which has aspired to the dignity of entertaining the royal guest, who had intended making there only a short sojourn on the road. This tube, recognizing that it must prepare a fitting chamber for one of honor, has also, upon short notice, added new furnishings which heretofore were foreign to so humble a house. A tubal decidua has formed about the ovum, which has increased in size as the ovum grew, until at the end of two or three weeks it is able to provide its guest with all the nourishment and necessities that the royal palace of the uterus could provide, only in cramped quarters. But the ambition of the tube has not reckoned with its capacity or powers of endurance, for the royal guest has so increased in size that the walls of the house are full to bursting and impending disaster threatens.

Thus, by fact, and somewhat by analogy, have we considered the pathology of tubal pregnancy. With that in mind, the recognition of the symptoms is comparatively easy. A sign seldom failing is an impression which the patient has, that she is pregnant. Particularly is this present if she has borne children. She will state that she is conscious of the lower pelvis, a peculiar indescribable sensation, which knowledge may be unusual to her; the abdomen is slightly sensitive, there is a pain in ovary or tube upon bowel-movements, there is some increased frequency of urination. She may or may not feel nauseated, but is likely to feel so after four or five weeks have elapsed.

The time comes for her menses, but no flow appears. If her habit be that of prompt regularity, this is almost a positive sign of pregnancy, but not necessarily of tubal pregnancy. In two or three days her anxiety is relieved by discovering a little flow, but this ceases perhaps after 6, 12, or 24 hours. This flow is caused by the uterus in its attempts to get rid of the unnecessary decidua, for be it remembered that the ovum now impregnated in the tube may have been lodged there four weeks previous, at the last menstrual period, and at the present moment, although she has missed but one period by a few days, she may have an ovum of four weeks' development in the tube; hence quite a decidua has formed in the uterus which it is endeavoring to cast off. She may mention that her breasts feel sore and her morning-sickness is increased. This periodic irregular flow of blood is an important sign.

Most of the above symptoms give to the physician a suggestion that the patient is pregnant normally, but this show of blood a week or so after the period is due, should arouse his suspicions that all is not right. He need not wait long for a confirmation of these suspicions: it will come if he is watchful. Next, he is told that there is more flow, which, like the other, lasts a few hours and then ceases, or may appear only when the patient is on her feet. She complains of an unpleasant sensation in the right or left ovary, it has become more sensitive, she avoids sudden movements or jars. About this time the patient may have sudden severe sharp pains in the sensitive side; these may be of a character to make her scream out in agony or fall in a faint upon the floor. These pains may be repeated in a few hours or days or may only come when she makes an exertion, but with each pain she is quite likely to have a little uterine flow. Now, it is not to be understood that this pain means a rupture of the tube, because a single tube cannot rupture every two or three hours or days, but it does mean that the tube has be-

come as full as it will hold with the constantly increasing ovum as a guest, and, because it cannot further stand such internal pressure, its peritoneal covering has begun to tear in places and the pain results. These tears may extend, not only through the peritoneum but through the entire tubal wall, and if they should happen to occur immediately over that portion of the surrounding decidua where the blood-supply is thickest, a very brisk hemorrhage will occur. Each of these tears seems to stimulate the uterus to contract, and hence we have an external show of blood. If a physician sat at the bedside of a patient whom he had never before seen, and she related to him such symptoms as above mentioned, he could not be excused for failing to recognize the true condition; but if he were in doubt he has the means at hand for satisfying himself beyond all question—the discovery, by a bimanual examination, of an enlargement to the right or left of the uterus. This may be as large as a walnut, a lemon, or an orange, or it may be bologna-shaped. It is extremely sensitive and must be handled carefully. It will also be seen by this examination, that the uterus is enlarged almost to the extent of the duration of the suspected pregnancy. The cervix will be soft and may be purple in color like a normal pregnancy. A few days later the physician may be told by the patient that her troubles are over with, as everything has come away and she shows him what appears to be an after-birth. It is so nearly like it he may not detect a difference, but his precaution will induce him to make an examination, whereat he finds that while the uterus is smaller than before, there is still the same lump in the side, just as sensitive, and the patient still has her symptoms of pregnancy. It was the decidua which has come away and not a placenta. Moreover, she will continue to have her agonizing pains, after each one of which she feels faint. She shows clearly now the loss of blood; her lips are pale, her eyes hollow, and she is constantly thirsty.

We will now suppose a period of from six weeks to two months has elapsed since the suspected pregnancy began. An urgent call reaches the physician to come to his patient immediately, she is dying. He finds her pulseless, blanched, breathing softly, cold and clammy. A friend says, "She screamed out with agony, put both hands over her lower abdomen, tried to get up and fell back fainting." We have finally come face to face with an issue which nature has been predicting forcibly, could we but understand her language.

The tube has ruptured from end to end, or such portion of it as contained the fetus. The thousands of little rootlets, which carried blood from the lining of the tube to the tubal decidua, have been torn open and are pouring quantities of blood into the abdominal cavity, or the ovarian artery may have been ruptured also, and thus is the hemorrhage increased. Even yet the patient is alive, hence there is hope of saving her, and it is far better to recognize the true condition and apply the remedy, even at so late an hour, than allow it to go unrecognized and cause death. I need not say that the one remedy is a rapid abdominal section, securing bloodvessels, turning out clots, filling the abdomen with hot saline solution and getting the patient back to bed as quickly as possible, with all means at hand for combating shock. But how infinitely better to have determined the question earlier and to have applied a similar remedy with one hundred chances in favor of success.

All orthodox rules have exceptions, so these rules of

symptoms have theirs, and these we must note most carefully. Our patient may never have been pregnant, hence she will not be able to tell us that she has such symptoms, but she can tell if she has any peculiar sensations low in the pelvis, whether faint or nauseated, with frequent urination, or if her breasts are sore. Again, she may have had an old salpingitis which has caused her much suffering and hence is never free from ovarian pain. But that will not prevent the delayed menstruation, the irregular gushes of blood, the well-defined tumor in the pelvis. We may fail in rare cases to have the delayed menses, but I have never failed to find such menstruation peculiar in some form; either it was exceedingly slight, which fact impressed the patient sufficiently to remember it, or it was so profuse as to be alarming, or it was intermittent. Next, we may not have the severe, sharp pains, due to peritoneal tears of the tubes, because the tube may not tear at all, but in their place we will find a steady, severe ache, never ceasing, and becoming more severe each day, owing to the steadily distending tube.

While the conditions enumerated may vary or fail to appear, there are three cardinal signs which will determine the diagnosis almost positively: First, some slight suggestion of pregnancy, with or without irregular gushes of blood from the uterus. Second, tubal or ovarian pain, either sharp, agonizing and periodic, or severe and continued with daily increase. Third, a lump on the right or left side of the uterus, sensitive, tense, and frequently pulsating. If you consider a moment you will recall that just this set of symptoms seldom accompanies any other one condition. A normal pregnancy seldom causes ovarian pain of a marked character, neither does it cause enlarged tubes that are sensitive and tense.

(To be concluded.)

A METHOD FOR THE GRAPHIC STUDY OF GASTRIC PERISTALSIS.

By CLARENCE QUINAN, M.D.,

Physician to Out-Patient Clinic, Medical Department University of California.

THE importance of ascertaining in any given disease of the stomach the energy of its muscle is generally recognized; it is the purpose of this paper to set forth briefly a method which is believed to throw an interesting sidelight on the problem. A description of the apparatus employed will be found in the *Occidental Medical Times*, San Francisco, November, 1899.

The gastric volumeter consists essentially of three parts: A rubber vesicle capable of being distended within the stomach and accurately filling the cavity, a graduated cylinder of 4,000 cubic centimeters' capacity for measuring the cubic contents of the vesicle after inflation, and lastly a water manometer for recording changes in tension. The apparatus is simple in construction and operation and of clinical application.

The stomach having been fully distended with air and communication established with a manometer, it will be seen that two forces operate to increase the tension of the imprisoned air, (a) descent of the diaphragm and (b) contraction of the stomach-muscle proper. Other more remote causes may effect some degree of increase of tension, as for example rectal spasm; but they may be disregarded: It should be borne in mind that occasionally they introduce a slight error.

The compression of the distended stomach, brought

about by diaphragmatic excursions, varies, as might be predicted, with the position of the trunk. It is most pronounced in the sitting position, the body bent forward. Here the stomach is evenly supported by the intestines, which block the lower portion of the abdominal cylinder; additional support being afforded by the

FIG. 1.—A new apparatus for determining the volume of the stomach and the contractile energy of its muscular walls. A. Recording cylinder graduated from zero to 4,000 cc. B. Wooden support with water or mercury manometer attached. C. Pressure bottle. E. Stomach-tube, soft rubber. G. Pressure-tube carrying vesicle. H. At extremity. I. Tube communicating with aspirator. K. Communicating at L with recording apparatus.

infolding of the anterior abdominal wall. It is somewhat less pronounced in the upright sitting, and is often nearly absent in the recumbent position.

The peristaltic wave will also be found to be affected by position, and it is probable that an uncomplicated wave is only obtainable when the subject is horizontal.

At the outset, it was assumed, that the stomach is rarely quite air-tight; it was therefore considered a wise precaution to take all measurements directly from the interior vesicle. One of the earliest and most surprising observations made, was that when inflated through an ordinary soft rubber stomach-tube, the stomach is quite air-tight and maintains for a long time constant tension.

The tracings here shown were made directly from the stomach without the intervention of a secondary membrane.

Method: One hour after a test-meal evacuate contents by aspiration without adding water; the fluid obtained is first measured, then brought into the filter; funnel at once for chemical examination.

FIG. 3.

Wash out with warm water, never using over 500 cc. at one time, repeat several times, always remove completely the water previously introduced before repeating operation. Now detach the stomach-tube from aspirating bulb and attach to the manometer; this connection should be made through the medium of a long rubber tube carrying a glass T-tube at its extremity, the remaining open arm of the T-serving for the attachment of a Davidson syringe.

The area of gastric resonance should be percussed out and mapped, before proceeding with inflation.

Inflation: Pinch off with the fingers of one hand the connection with the manometer and force air into the stomach till patient complains of pain or discomfort.

FIG. 2.—Norma stomach tracing. Patient sitting and inclined forward.

Not infrequently, however, cases present themselves which can only receive satisfactory investigation through the employment of the vesicle, otherwise air passes rapidly out of the stomach through the pylorus with a peculiar sizzling sound, and constant tension is only attained when the entire abdomen is quite tense.

This will very rarely occur before the manometer records a pressure of two inches or more. The fact that a pressure of two inches is easily borne has led to the adoption of this as the regular working-tension.

A very buoyant glass float, carrying a simple tracing-

device serves to record on the drum of the kymograph the excursions of the water-column.

CASE 1.—*Chronic Mucous Gastritis with Motor Insufficiency*, occurring in a man aged 41 years, a teamster, native of Sweden. His family history is negative; there is no transmitted neurotic taint, and his habits are temperate. His health

by movement. The attack lasted three weeks. Previous to the attack his bowel-habit had always been regular, but was variable ever since, constipation being the rule.

The present trouble began with pain in the epigastrium several hours after eating, loss of weight during the last year from 190 pounds to 150 pounds. He has occasional headache, excessive appetite, and constipation, but says he

FIG. 4.

FIG. 5.

was good in early life and manhood, but he had gonorrhea 5 years ago, and twice since. He denies lues. He has had constipation since the fall of 1892. He has always been an immoderate eater.

At present he complains of a feeling of weight and uneasiness in the epigastrium some hours after eating, exaggerated by dietary excesses, but rarely painful in degree. He has a bad taste in the mouth, headache, lassitude, insomnia, chronic constipation, occasional nausea, but rarely vomiting.

Examination—The patient is of the neurasthenic type, thin, but with good color, the pupils are equal and react to light; there is symmetric development; the abdomen is depressed, and the umbilicus everted.

The heart is negative to examination, the arteries soft, the pulse regular, with moderate tension. The blood-counts two hours after eating showed erythrocytes, 3,620,000; leukocytes, 7,400; hemoglobin, 80%.

The liver and spleen were normal; the abdomen was tender to pressure under the xiphoid cartilage, but negative elsewhere. The urine is pale, clear, with a specific gravity of 1.020; there is no albumin and no sugar, but a heavy phosphate cloud on heating; one or two hyalin casts were found. The superficial reflexes were intact, and the knee-jerks lively. A few enlarged glands were seen in the inguinal group. The stomach-contents were withdrawn one hour after a test-meal to the extent of 150 cc. There was some odor and much mucus, and free hydrochloric acid present; the filtered juice-digests coagulated white of egg freely and reduced Fehling's copper solution instantly. The position of the stomach before and after inflation is shown at A and B, Fig. 3. A tracing in the sitting position, inclined forward, is shown in Fig. 4, and a tracing in the horizontal position in Fig. 5.

The experiment was conducted quietly, the patient being under no mental or physical excitement.

CASE 2.—*Dilation with Loss of Motility, Arteriosclerosis, Contracted Kidney*.—The patient was a man, aged 42 years, boiler-maker, and a native of Ireland. His family history was negative and he was of temperate habits. He had been healthy as a child, but had gonorrhea at 18 years, and once since; he had syphilis in 1893 and had taken three months' treatment. In February, 1899, while in perfect health, he was seized with severe pain in region of umbilicus. The onset was sudden, and he had frequent bowel movements accompanied with pain and tenesmus; there was much blood in stools, and pain at the umbilicus always relieved

sleeps well and never vomits. Pain is always relieved by raising the contents of the abdomen upward and backward by pressure from below. The patient is fairly nourished, muscular, and has a good color; the pupils are equal and react to light; the tongue is fairly clean, there is symmetric development of thorax and abdomen, but distended

FIG. 6.

venules on the free costal border on both sides. The hands are cold, purple, and there is a fine tremor in the right. The abdomen is prominent. On examination of the heart no visible impulse was disclosed; the apex-beat was in the mid-mammillary line, one inch below the nipple, the dullness increased slightly to the left. There is an accentuation and reduplication of the second pulmonic sound, and marked

accentuation of the second aortic. The radial and brachial arteries are hard and tortuous, the pulse shows somewhat high tension, but is regular and synchronous. Blood-count two hours after eating shows erythrocytes, 5,160,000; leukocytes, 8,600; hemoglobin, 80%. The liver is enlarged, the lower border smooth, and palpable one inch below the costal margin. The spleen is normal. The glands are enlarged in

sterility was the cause. At the present day, however, no such statistics can be given because wilful prevention of conception has, among a portion of the community, almost become the fashion. Dr. Woods Hutchinson, in "The Gospel According to Darwin,"¹ a small book which I urge you most strongly to read,

FIG. 7.

FIG. 8.

the inguinal region, on both sides and in both posterior cervical triangles. The superficial reflexes are intact, the cremasteric slight, and the kneejerks are lively. The urine is clear, dark in color, with a specific gravity of 1.032, a faint trace of albumin, no sugar; hyaline and finely granular casts exist in large numbers. The stomach-contents were 300 ccm. in amount, faintly acid in reaction, but with no free hydrochloric acid; it reduces Fehling's copper-solution at once. The filtered gastric juice digests coagulated egg-albumen after an addition of dilute hydrochloric acid.

The position of the stomach before and after inflation is shown by A and B in Fig. 6.

A tracing in the recumbent position is given in Fig. 7, and a tracing in the sitting position, inclined forward, in Fig. 8.

Inspection of the tracing from the normal stomach shows it to be double, an abrupt, frequent diaphragmatic wave being superimposed on one much slower and of longer duration. This last is considered to be of peristaltic origin, the ratio between the waves in the normal tracing is nearly as 18 to 1. In the tracing of Fig. 3 the ratio is evidently altered, while in Fig. 6 it is quite atypic, some diaphragmatic influence being evident.

The average time-interval for each tracing was 2 minutes and 30 seconds.

It is suggested that the height of the peristaltic wave measured from base line to apex gives in terms of a water-column a direct measure of motility. Data now available show this to vary between $\frac{3}{4}$ and $1\frac{1}{2}$ inches in health.

ARE CONSANGUINEOUS MARRIAGES INJURIOUS TO THE RACE?*

By LAWRENCE IRWELL, M.A., B.C.L.,
of Buffalo, N. Y.

(Concluded from page 132.)

SANSON says the influence of consanguineous marriages is to raise heredity to its highest power, and according to Lacassagne, it is not, in a word, the consanguinity in itself which is healthy or morbid, but the ground upon which it is exercised. I refrain from wasting your time in attempting to discuss this point any further. The 3 authorities I have quoted, probably gave accurate statistics of childless marriages in which

says, "The latest and most extraordinary development from the theory of the sinfulness of sex, is that which is, in these latter days, brayed into our ears from every 'suffragist' platform—that child-bearing, instead of being a factor in woman's development, is absolutely a hindrance to her higher education, a clog upon her freedom, and a mortal enemy of 'culture.' In fact, as a 'club woman' tersely expressed it to a friend of mine a few months ago, 'Only fools bear children.' There is only one thing which need be said in regard to this delusion, and that is, that it has its uses. It prevents the continuation of the breed. Neither the 'emancipated' woman at one end of the scale nor the prostitute at the other, propagate their kind, and society has reason to be thankful in both cases."

The percentage of unfruitful marriages, whether you take consanguineous unions or not, is dependent upon the country under investigation, upon the particular period selected for inquiry, and upon the class of the community to which the statistician devotes his attention.

Bearing in mind the lamentable fact that barrenness is no longer the only cause of the absence of children, I feel that the most any cautious investigator can assert is that sterility as a consequence of the marriage of blood-relatives has not been proved.

Breeders of stock frequently breed "in-and-in" for some years, not only with impunity, but with marked benefit. But this fact, while going to prove that it is not the mere blood relationship of the parents which induces the degenerate conditions so often found among the children of consanguineous unions, can very seldom be advanced as an argument in support of the marriage of near kin. The farmer only permits the more perfect members of his flocks and herds to continue their kind, and for this reason the "in-and-in" breeding is innocuous, unless continued so long that dwarfing followed by sterility occurs, which appears to be the case with some animals. Under like conditions a limited amount of in-breeding among ourselves would be harmless. But where are we to look for the perfect human family? At the present day such families are very rare indeed. The laws of evolution have been so strained and perverted by our so-called "civilization" that almost every family has a defect of some kind, and as all such imperfections are transmitted and increased by intermarriage such unions should be discountenanced.

* My original intention was to read this paper before the Sociological Section of the American Association for the Advancement of Science. Its length, however, made that course impolitic, if not impossible.

The neo-Lamarckian school of biology, which believes that "acquired characteristics" are usually passed on from one generation to another, admits that noncongenital characters of a pathologic nature are liable to disappear when the individual bearing such characters chooses a partner free from similar defects. This admission is of the nature of a concession to neo-Darwinism. The natural tendency, say the followers of Mr. Spencer and the late Professor Eimer, is for the offspring to revert to the normal type, so that, unless the defect is very deeply impressed upon one parental organism, it may not reappear in the offspring. It is necessary to remember, however, that certain disorders, such as gout and hemophilia, generally descend in the male line, allowing the females as a rule to escape. The former disorder is said by Sir William Roberts² to be an example of an acquired pathologic characteristic which is hereditary, a claim which has not yet been made for an abnormal tendency to bleed. Leaving controversial questions on one side, it may safely be asserted that when both parents are possessed of a physiologic or pathologic congenital characteristic, that characteristic is almost certain to be repeated in an aggravated form in the offspring.

If there be any congenital taint in a family, each member will have inherited more or less of it from the common ancestor. Take the case of cousins, the descendants of a common grandparent who was insane, and of an insane stock. Here the cousins are certain to have inherited more or less of the insane diathesis. Even if the taint had been largely diluted in their case by the wise, or more likely fortunate, marriages of their blood-related parents, yet they will have inherited a certain tendency to nervous disorders, and if they marry near relatives they must not be surprised if that taint appear in the form of serious disease in their descendants. Some of the children of such parents are usually idiotic or epileptic, and the relatives wonder where the imperfection came from. It may have happened, in some instances, that neither the parents nor the grandparents of the children have shown any outward signs of the tendency to the disorder which they have inherited and have handed down, and not looking further back, the bold assertion is made that insanity and epilepsy are unknown in their family. The truth is that very few of us are in possession of any accurate information concerning our ancestors further back than our grandparents, and a family history of less than four generations has only a limited value.

The popular impression of the heredity of disease is that a specific malady is passed on from one generation to another. The following quotations from recognized authorities will show that this idea is erroneous: Moreau, of Tours, in his "Psychologie Morbide," says, "It shows an incorrect conception of the law of heredity to look for a return of identical phenomena in each new generation." Morel, the author of "Traité des Dégénérescences," writes, "We do not mean exclusively by heredity the very complaint of the parents transmitted to the children, with the identical symptoms, both physical and moral, observed in the progenitors. By the term heredity we understand the transmission of organic dispositions from parents to children."

While anxious to avoid any argument which might partake of an *a particulari ad universale* character, I venture to mention three families in which intermarriage has been quite common. The present ruler of Great Britain, Queen Victoria, is the daughter of

cousins; she married a cousin and has a large family of sons and daughters, most of whom, as well as her grandchildren, are unquestionably normal. There have, of course, been marriages outside of the family. As the blood of the Guelphs has never been absolutely of the best, considering the amount of intermarriage that has taken place, it is surprising that the signs of degeneracy are not markedly conspicuous.

The family of the English Earl of Derby has intermarried very frequently since its foundation about five hundred and fifty years ago. The fourteenth earl, the son of first cousins, was prime minister. Of his three children, the eldest was a statesman of quite the first rank. The present holder of the title, his brother, has been secretary for war and governor-general of Canada. The third is Lady Emma Talbot.

The Rothschilds, the world-renowned bankers, have usually married cousins, and marriages outside the family have been the exception. In spite of this the decay of these hereditary financiers appears to be very far distant. If one is of an orthodox turn of mind, the escape of the Rothschilds from idiocy, insanity, and deaf-mutism may be attributed to the fact that they belong to "the chosen race."

In consanguineous marriages the real danger is in the strong probability that both parents bear some distinct taint of degeneration, which is liable to be increased in their children, but which might possibly disappear if each married a person not bearing the same or some closely allied character. The blood-relationship in itself is not to blame; it is the double tendency to disease which brings the injury to the children. The marriage of two individuals of the phthisical type, whose families were strangers to each other, would be as productive of evil as the marriage of first cousins who were phthisically inclined.

It will not be out of place here to refer to the similarity of temperament produced by a common environment, which is a potent factor in the production of pathologic phenomena. Persons living under similar and unhygienic conditions, working at the same unhealthy occupations, or indulging in the same dissipations, appear to acquire like disorders. Hence it happens that individuals who are not related by blood are of identical temperament. What I propose to call "identity of environment" has been a cause of decay in the aristocracies of Europe, although acquired disorders are not, in my opinion, "hereditary" in the true sense of the term. I have frequently pointed out, however, that any mode of life which debilitates the soma (to use Weismann's terminology), must react upon the germ-plasm, just as the starvation of a host will injure a parasite living upon it. This condition may be called "pseudo-heredity" for want of a better name, and it explains to some extent the manner in which "identity of environment" acts injuriously upon the race. The important part which it plays, both positively and negatively, is well illustrated in the case of the portion of the community to which I have the honor by birth to belong—the Jews. The intermarriage of blood-relations has taken place from the earliest times, without, as far as I can judge, any harmful results. Indeed, for centuries the Jews have maintained a physical and intellectual standard well up to the average, if not above it, in spite of frequent oppression. It must be admitted, however, that until a few decades ago "identity of environment" was absent. The Jew was for centuries a wanderer upon the face of the

earth; a veritable rolling stone, though differing from the proverbial rolling stone in its one great characteristic. For many years he was without a country, consequently without patriotism, and was comparatively seldom a soldier. But, except upon the battlefield, there was no spot on the earth's surface where riches and honor were obtainable that the Jew was not to be found. In the past he has had few ties and has loved one country little better than another, two facts which account for his roaming all over the world in search of wealth. This incessant wandering produced such diverse temperaments that anything approaching the identity of character, to which I have referred, was impossible. Within the past sixty years, however, the Jewish mode of life has materially changed. Having abandoned our nomadic habits, we have become Englishmen, Americans, Germans, or Frenchmen, and we have already acquired some of the vices and some of the diseases, as well as a few of the virtues, of the various nations to which we have attached ourselves. For example, *tuberculosis pulmonalis*—sometimes called "the great white plague"—which is responsible for from one-fourth to one-seventh of all the deaths in the civilized world during any year, appears to attack us more frequently than it formerly did, although phthisical Jews are still far from numerous. To put the facts in another way—the roaming of the Semites of old, aided by frugality, appears to have prevented the acquisition of the tuberculous diathesis, a predisposition which every sufferer from pulmonary tuberculosis inherits or acquires prior to the attack of the Koch bacillus. Again, Jewish drunkards have been very uncommon in the past, the late Dr. Norman Kerr, in his book upon "Narcomania," relating that he has been consulted for inebriety by only one Jew, although his advice for this curious disease has been sought by a great many persons. Unfortunately, conditions have changed, and excessive indulgence in alcoholic drinks, often in quantity conversationally called moderate, is no longer as great a rarity among well-to-do Jews as it used to be, a result, in my opinion, of the environment with which we have now surrounded ourselves. If we Jews have a sincere desire to live in posterity, in addition to shunning the various environments, which have been a productive source of disease and decay among so many of the civilized peoples of the world, we must marry no later than our thirtieth birthdays, otherwise the large families, so frequent among the Jews of early times, are not likely to be continued. Without asserting that any advantage will accrue from the preservation of pure Semitic families, I would urge that their blood is more often free from taint than is that of any other people; and that, when such is the case, and where the temperaments of the contracting parties are unlike, close relationship need not be regarded as a bar to marriage. While the Jewish character, as indicated by the type of face, may appear to the casual observer to be permanently fixed, there can be no reasonable doubt that, after a few generations of intermarriage with persons not of Jewish blood, the distinctive characters, both physical and mental, would disappear.

The English Jews marry their first cousins to the extent of 7.5% of all marriages,³ against a proportion of between 2% and 3%⁴ for England generally. If, therefore, unions of cousins tend towards sterility, that tendency ought to be apparent among the Hebrews of the United Kingdom. Statistics upon this point are quite unnecessary, since large families among the Eng-

lish Jews are recognized as the rule, not the exception. It is a remarkable fact that marriages between Jews and non-Jews are somewhat infertile. In Prussia these marriages have been separately registered since 1895, and between that year and 1881 there was an average birth of 1.65 to a marriage, whereas, during the same period pure Jewish marriages resulted in an average of 4.41, or very nearly three times as many. In Bavaria, between 1876 and 1880, the numbers were only 1.1 per marriage against 4.7 to purely Jewish marriages. Whether this conspicuous infertility implies greater sterility I cannot say. But Mr. Joseph Jacobs⁵ investigated 71 marriages between Jewish cousins and found that 5.4% of them were childless, while in 56 cases of mixed marriages 9, that is, 18%, were nonproductive. There is, it is true, a possibility that the comparative infertility of unions between Jews and non-Jews may be due to the higher age at which such marriages generally take place. There is a feeling against them among all strict Jews, which is only likely to be overcome after independence of thought has been reached. I cannot convince myself, however, that this attempted explanation is of much value. We must not assume, of course, that the crossing of any two races has the same results as the crossing of Jewish and non Jewish Europeans may seem to have.

In spite of what I have said in reference to the Jews, consanguineous marriages must, as a rule, be dangerous in civilized communities like those of this country and Great Britain. Where the process of Natural Selection has been so markedly modified, they should not be entered upon. But we must admit that just as we can cultivate by "in-and-in breeding" pathologic or degenerate characters, such as the insane, tubercular or uric-acid diatheses, so it is possible, by means of the intermarriage of those belonging to a family noted for some physical or intellectual excellence, to fix that good character in the family. Thus the marriage of cousins in whom mechanical or artistic talent is prominent will, in all probability, produce children in whom the particular talent of the parents will be still more strongly marked. A good example of this may be found in the numerous family of Bachs, the musicians, who freely intermarried, and elevated their talent, possessed to all, to the level of genius in some of their members.

In this manner many characteristics which have been congenital with both parents may be transmitted, possibly deepened with each transmission, and perhaps fixed as a constant character in the family. Moreover, as congenital variations—what may be called "accidental characters"—are undoubtedly transmitted in many instances, especially the father's peculiarities to his sons and the mother's to her daughters, these may be, to some extent, fixed in a family. This is constantly done by breeders of our domestic animals. But I am unable to find any satisfactory evidence that man can pass on to the next or some future generation any quality that he acquires during his lifetime, although I have very carefully studied the cases cited by the late Professor Eimer and Mr. Herbert Spencer.⁶ We know, of course, that if a parent injures his constitution by "riotous living" his children will suffer. But this is not true heredity, and is merely an instance of pseudo-heredity.

Supernumerary fingers and toes have been a common deformity in the human species since the days of David, when "Jonathan, the son of Shimei, the brother of David," killed in battle the Philistine of great stature,

who "had on every hand six fingers, and upon every foot six toes, four-and-twenty in number." Concerning this variation, Lawrence, in his lectures on "The Natural History of Man," says: "If the six-fingered and six-toed could be matched together, and the breed could be preserved pure by excluding all who had not these additional members, there is no doubt that a permanent race might be formed, constantly possessing this number of fingers and toes." This assertion is by no means extravagant, for congenital peculiarities in one animal are often taken advantage of by cattle-breeders in order to reproduce and fix them as constant characters that are desired. The best example that I can recall is the Ancon or Otter sheep. The peculiarity of this variety of the sheep family, which became very popular, but which has now been allowed to become extinct, first appeared in a somewhat deformed lamb, born of ordinary parents, in Massachusetts, in 1791. The animal was of curious structure, and his offspring in many instances had the same characteristics as he had, which were shortness of the limbs, and great length of the body in proportion to the legs. The joints were exceptionally long and the forelegs crooked. The principal reason for the propagation of this variety of sheep was the inability of the animal to jump over fences.

Although consanguineous marriages might be used to develop desirable characters in some families, such attempted cultivation of genius is seldom to be advocated for the following reason: Few families are perfect; most of them possess, at least, some pathologic tendency, and while the desired character was being deepened and fixed by successive consanguineous unions, in the majority of instances some very undesirable character would be simultaneously built up. The latter would increase as surely as the former, and on reaching the necessarily fatal degree sterility would make its appearance. For this reason, if there were no other, family consanguinity should generally be avoided in marriage, although there may be exceptions to the rule.

From time immemorial it has been known that "the introduction of new blood" has a beneficial influence upon the family or the race, and proof of the truth of this old-time doctrine is to be had on every hand, both in the human family and among the lower animals. I have been informed that the ladies of the German capital, Berlin, who are most noted for their beauty and their intellectuality, are the descendants of French ancestors who married into Prussian families. In Ireland, however, there is positive evidence of the beneficial effect of "crossing." In the counties of Tipperary and Limerick, where great numbers of Cromwell's English soldiers settled, the people are noted for their splendid physical development and their courage, though not for their wisdom or discretion. In Ulster, where the lowland Scots placed there by James I of England have blended with the Celt, the present inhabitants are physically superior to the people of any other part of the United Kingdom, while in energy and mental capacity they have few superiors. I think I may safely assert that the superiority of mixed races is almost always evident to the traveler in Ireland, if he is a careful observer of the human species. Pritchard, in his "Researches into the Physical History of Mankind," says, "In some parts of Ireland, where the Celtic population of that island is nearly unmixed, they are, in general, a people of short stature, small limbs and features; where they are mixed with English settlers, or with lowlanders

of Scotland, the people are remarkable for fine figures, tall stature and great physical energy."

Now as to the lesson which I venture to draw from such evidence as I have presented. We learn in the first place that consanguineous unions are, in the great majority of cases, undesirable, not because they originate diseases *de novo*, but because they intensify existing disorders or diatheses, from which very few families are exempt. With our incessant efforts to counteract the process of natural selection, such marriages are becoming more and more dangerous every year, and, as a general rule, they should be discountenanced, even in the most healthy families, for there is always a possibility that such unions may wake up some dyscrasia which has been latent for several generations.

Secondly, consanguineous marriages should not even be thought of in any family in which idiocy, insanity, epilepsy, congenital deaf-mutism, hare-lip, cleft-palate, the phthisical or lithemic diatheses have occurred, for all of these diseases or tendencies towards disease may be handed down from one generation to another. Permit me to urge, however, that neither identical disorders nor identical symptoms need be expected, for the transmutation of pathologic conditions is an everyday occurrence.

As it is not improbable that cancer is a microorganic malady, which only attacks those persons who have a proclivity towards it, families in which cancer has appeared, no matter how far back, should avoid consanguineous unions.

Finally, I would urge that frequent marriages of persons whose environment has been very similar is injurious to the race, and that extreme exclusiveness in marriage is not commendable. If the supreme desire of the aristocrats of this republic is to perpetuate their name, they must oxidize their "blue" blood to arterial red by marrying into families which have not been exposed for three generations to the enervating influences of city life.

And if the diseased and the degenerate insist upon marrying—as they certainly do—it is their duty to consider the next generation. I implore them in the name of science and in the interest of humanity to mitigate their innate unfitness by the selection of suitable consorts. Let the feeble marry the robust, let the neurotic espouse the level-headed, and brave the anger of the blind god Cupid.

In this paper I have used the term "deaf-mutism" in the manner in which it is usually used by the medical profession. I must add, however, that it appears to me—I am not a physician—to be in every instance a symptom and not a disease.

Bone-Abscess Due to the Typhoid Bacillus.—Paul Bush and J. O. Symes (*Practitioner*, April, 1900) conclude that scattered foci of suppuration arise as follows: the typhoid bacillus passes from the bowel into the portal system, is carried to the liver and enters the bile-channels and finally the gallbladder, when suppurative cholecystitis will form. Or a general blood-infection may take place and local foci of suppuration are excited either by the lodgment of the bacteria in tissues of low vitality, or by masses blocking minute vessels. [M. B. VOL. VI, No. 5

AUGUST 4, 1900

\$3.00 PER ANNUM

The Medical Service in South Africa.—The British public is having the same kind of disagreeable sensation that the American people had after the Spanish War. Some one has come home from South Africa and has pitched right and left into the medical service of the war. The critic is Mr. Burdett-Coutts, who has the advantage of having a seat in Parliament from which he can make himself heard. In a recent speech (June 27) he distinctly stated that grave abuses have existed, especially with reference to the distribution of medical stores, and as to the prevention of enteric fever. As we understand, Mr. Burdett-Coutts does not attack the *personnel* of the Army Medical Corps, but on the contrary, speaks highly of the devotion to duty of both surgeons and nurses. It is the organization and administration of the service that are especially criticised by him, and we take it, his criticism indirectly applies to the staff and line officers for not taking more council with the medical authorities. This is possibly only another phase of the nasty personal feeling that exists between the general and the medical staff in the British Army. This feeling has grown largely out of the fact that the English Army has been made the exclusive preserve of the privileged and wealthy classes, who affect a caste superiority over noncombatant officers (as they call their surgeons). As many of the disasters of the British Army in the South African War are attributed to the incapacity of these social favorites, it is to be hoped that, if these men are also, even indirectly, responsible for mismanagement and abuses in the medical service, Mr. Burdett-Coutts will succeed in holding them up to the public gaze. If a supercilious disregard for medical and sanitary science is to be added to their other shortcomings, they will, indeed, appear in a most unfavorable light. Unfortunately this attack by Mr. Burdett-Coutts is open to the suspicion of being actuated by partisan spirit—just as such attacks are too apt to be in the United States. We trust, however, that if there is anything in his critical grist, it will be threshed out; and for this purpose the whole subject has been referred by the British Government to a commission of eminent citizens.

Medical Colleges Should Live Up to Their Announced Requirements.—An earnest young physician of high scientific attainments, having been recently appointed to a teaching position in a certain medical

college in an inland city, made this remark to a professional friend: "I am ashamed for my college and myself when I come to examine the papers that my students present. The lack of a proper education in English is so apparent that I feel certain half of our students could not pass a rigid examination for entrance into a good high school." Yet the college with which he is connected professes to live up to the requirements of the Association of Medical Colleges. A great deal of the professional education given therein is quite up to modern standards,—but some of it does not come up to what it professes to be. Faculties and professors need not imagine that the students themselves are blind to the inefficiency of methods that characterizes some of the colleges. The young men realize their own shortcomings and the shortcomings of their instructors only too vividly. But some of them become impressed with the fact (?) that it is all right to mislead each other and also the public, and from this class the quacks of the future will be recruited. Charlatan professors make charlatan graduates. Ignorance begets ignorance. That "professor" who feels that he must, in the spirit of loyalty to his college, supply at least three students each year, even if he recruits all his barber, drug clerk, or coachmen acquaintances, is doing a woful injustice to the whole profession. Let the schools cast out such men from the ranks of the faculties. And if the casting-out process is so extensive as to result in the final disintegration of a few faculties or the disappearance of a few schools which find it practical to "amalgamate" so that one college will eventually do the work now performed by three, the mourning will be neither very deep nor very long continued.

Mendicancy and Vagrancy.—Men and women are not beggars and tramps by choice, and careful, systematic inquiry would often disclose some fundamental reason for deviations from the normal in this respect. At a recent meeting of the Association of German Alienists Bonhoeffer (*Wiener medicinische Wochenschrift*, 1900, No. 27, p. 1333) reported the results of a study of 400 mendicants that came under his observation as prison-physician in Breslau. The large proportion that were ineligible for military service (70%) and the barrenness of the marriages (half of the marriages were sterile, 120 children being born as a result of 100 marriages) were especially marked features. Half of those

examined presented hereditary defects (9% actual psychoses, 12% epilepsy, 29% alcoholism), taking into consideration only recent ancestors. The intellectual level was extremely low. Not less than 22% could be considered imbeciles. The first penal offence was generally theft; after this in frequency followed offences attributable to alcoholism (crimes against person, etc.). Acquired psychoses were present in 6%. Eighty-seven per cent. were habitual drunkards, the alcoholism being of degenerative origin in the majority and acquiring independent significance in not more than one-fifth. The first offence was committed principally between the fifteenth and the twentieth year (beginning of the period of self-support), next between the twenty-fifth and the thirtieth year (period of greatest competition) and then between the thirty-fifth and the fortieth year (alcoholic ruin). In accordance with the period at which criminality begins two groups of cases can be distinguished. In the one, socially the more dangerous, imbeciles and epileptics play the most important part; in the other alcoholism and acquired psychoses. The fertility of the latter is twice as great as that of the former.

The Title Doctor.—Mr. Jasper, Borough Superintendent of Schools in New York, deserves the thanks of the medical doctors, and as he is getting anything but thanks from the philosophic variety we should not be slow with our gratitude. He became tired of the degree-possessing doctors, who savagely claimed their titles, and of those whose meekness in accepting them was equalled by their undesert, and he cut the difficulty by commanding that without exception all should be plain Misters. It is so easy now to get any sort of a degree from our modern colleges that our professional title was in grave peril of being taken from us. In view of the invasion of pothouse politicians, stock-brokers, and the rest, among the LL.D.'s, of the tremendous growth of Doctors of Philosophy, Divinity, Osteopathy, Christian Science, etc., etc., it was fast becoming impossible for one to know whether a person addressed as Doctor was learned in medicine, in anything, in everything, or in nothing; whether he had inherited or bought a degree, or had carelessly assumed it; whether he practised, or only preached. Some are born erudite, some achieve erudition, and some, we suppose, do have it thrust upon them. Plainly, the only thing left for the poor medical man, if he would be differentiated at all, was to accept the Western colloquial degree of Doc. Certainly none more aristocratic than ourselves would consent to be called Doc. And yet we have in English a strange and pressing need for a general term wherewith to address strangers. In all other nations one can address a man or a woman by a general term appropriate and polite. The taciturn Englishman, when his language was making, felt no such a need. The friendly and democratic American does

feel the need and most acutely,—“Mister” and “Lady” have been devised by the waiter. The ingenious aristocratic American, it would seem, has determined upon a partial solution of the great problem. He first tried Colonel, but peace is against that; Senator would have done nicely, but the number admissible to the Senate is limited and not everybody can be a rich politician. Everybody, however, can be learned or can so easily be certified as learned, and hence we may safely address any self-important man hereafter as Doctor.

The Cost of Publishing a Medical Journal.—We sometimes receive letters implying that the publishers and editors of medical journals must be “making a mint” of money; asking why we do not discontinue advertisements; and criticising the financial management in general, very general, terms. We wish such critics would weigh the public statement of the trustees of the American Medical Association read at the last meeting and since published in the *Journal* of the Association. Including the figures for the two preceding years we find the

	1897.	1898.	1899.
Expenditure of Journal office . . .	\$45,637.67	\$58,202.21	\$77,041.01
Subscriptions, and membership fees, and sales	{ not differentiated.	{ 42,931.41	{ 55,513.25
Balance			
Advertisements		\$15,268.10	\$22,127.76
		23,629.91	33,760.82
Profits		\$8,361.61	\$11,633.06

These figures illustrate how close is the margin of profit in a journal with a printing plant worth \$21,000, whose subscription price is \$5 a year, and which has the tremendous advantage of the Association behind it,—each member being a subscriber.

When we come to examine in detail the reason for this we find it to consist principally in the nonpayment of subscriptions, and the need of a large number of free copies. Thus, according to the trustees' report, we find that the membership and registration fees and dues were in 1899 as follows:

Registration fees at Columbus Meeting	\$ 6,125.00
Membership fees one year	32,840.00
Subscription fees one year	9,488.00
Total	\$48,453.00
Divided by 5	9,690.

as the actual number of paying subscribers or members for 1899.

According to the report the weekly average of copies printed was:	13,672
From which deduct	9,690
Leaves copies unpaid for each week average	3,982

To learn what portion of these 4,000 unpaid for copies are unpaid subscriptions and what portion are used as sample copies we quote again from the report, the “Count of Mailing List:”

	1899.	1900.
Copies to members and subscribers on Jan. 1	10,450	13,078
Per issue, an average for the year of		11,754
Weekly average of copies printed		13,672
Weekly average for free distribution		1,908

In round numbers, therefore, 2,000 subscribers do not pay cash for their subscription, and 2,000 copies are used as sample copies to get new subscribers.

In another way the financial profits of the whole history of the Association viewed as a business investment may be summarized as follows :

Cash on hand, January 1, 1900	\$ 4,131.36
Invested in loan and U. S. bonds	13,812.50
Recapitulation of inventory	\$21,031.50
Less unpaid on same	5,935.00
	15,096.50
Total, half century profits	\$33,040.16

It is plain that as an investment a capitalist would not look upon this showing as very alluring. Of course we are most keenly aware that the Association was never meant to be viewed in that way, as it is actuated by other ideals than financial ones. We reproduce the figures merely to remind physicians to pay their subscription accounts and to endeavor to set right a few physicians who have false ideas of medical journalism and its methods. Success in it can only be attained by a large income from advertisements. Without that \$33,760.82, derived from its advertisers last year, it is painfully evident that the *Journal* of the Association would have been ruined in a year.

If this is so as regards our most esteemed contemporary, with a subscription price of \$5 and with a paying list of annual subscribers presented without commission or seeking, how true it must be with a journal like our own published at \$3 a year, without a printing-office plant, and compelled to hunt up its subscribers! We infer from the trustees' figures that each copy of the *Journal* sent to the 9,690 paying subscribers last year cost to make and mail over eight cents each, or over \$4 annually. As the PHILADELPHIA MEDICAL JOURNAL is published by a solvent company each copy is produced at less than six cents, and by the year at less than \$3. We are glad there is such a professional journal as that of our honored colleague freed from the commercial slaveries that bind the rest of us. Were it not against command we should envy him this and many other blessings. Not the least would be the \$90 above the salaries allotted him each week by the generous trustees for editorials. If we were only competent, if we could hope to reach the standard,—we would speedily apply for a humble place on the editorial staff!

Recrudescence of Epidemics of Infectious Diseases.—It is now well recognized that diphtheria may persist in latent form for many months, and that persons may carry virulent diphtheria-bacilli in their throats or elsewhere for a long time, and be a constant menace to those with whom they come in contact so long as the bacilli persist. It is also well known that typhoid bacilli may persist in some of the tissues for more than a decade, and that consequently persons who have had typhoid fever may be capable for a long series of years of infecting their surroundings. Such observations have thrown a new and strong light upon the mode of infection in many cases which previously seemed in this regard to be absolutely inexplicable.

The fact that diphtheria and typhoid bacilli, as well as certain other organisms which are readily recognizable, may persist in virulent form in a person who has had these diseases has been demonstrated with relative ease, because the organisms causing the diseases are well known. Some important observations bearing upon the question of the spread of infectious diseases of more obscure etiology are described by Lippmann (*Deutsche med. Woch.*, June 7, 1900) and they are of much importance in leading to an understanding of the frequent recrudescence of epidemics of infectious diseases, particularly in institutions. The most striking case was that of a boy who had a typical attack of scarlet fever in which the tonsils and glands of the neck were much enlarged. The glands remained large after the attack had passed, but he apparently recovered entirely after normal desquamation. Some weeks afterward hot applications were made over the glands in the attempt to reduce the swelling. The glands did decrease in size, but there was at once another outbreak of scarlet fever with typical symptoms, course, and desquamation. One could scarcely escape the impression that the glands had contained the organisms which cause the disease, and that with their rapid reduction in size these organisms reached the circulation again and caused a new attack. Lippmann describes a number of other cases in which there was apparently a persistence for years of latent scarlet fever associated with enlargement of the glands; attacks more or less closely resembling scarlet fever appearing repeatedly after a typical attack of this disease and persistently recurring for years until the glands were removed, or until the swelling of the glands had disappeared. He also mentions analogous occurrences in other diseases, particularly directing attention to similar recurrences of erysipelas, and states very properly that we must always suspect that recurrences of infectious diseases may be seen or that the disease may be transmitted to others so long as there are evident remnants of the disease in the form of glandular enlargements or other macroscopic changes. Probably there is often the same danger even when macroscopic changes are not apparent. While the observations do not contain an essentially new idea they do furnish new evidence that the danger of transference of infection is by no means past when the ordinary evidences of the disease have disappeared, and that we must strive to discover more satisfactory methods of getting rid of the remnants of infections and of learning when danger is past.

Medical Sermonets, No. 21. A Plea for the Humanities in Nursing.—The nursing profession has yet to find its historian, and when he (or she?) shall commence his work he can hardly do so with a later reference than to the story of Adam and Eve, in Genesis. Nursing must have begun with the first labor, or at least with the first baby. To nurse is to nourish, and the etymology of the word shows that the professional use sprang from the most primal of

needs and the most sacred of affections. In the earliest historic times, and in those prehistoric days echoed by folklore, sacred writings, legends, and poetry, we find that suffering and illness rarely failed to call forth that tender helpfulness from which has come the modern nursing profession itself. In the Arthurian legends this function of women was so well-recognized and fulfilled that we find it constantly alluded to in all the writings. How instructive and spontaneous it has been, and how clearly it sprang from religion and love in our Puritan ancestors is manifested by the following quotation:

"But that which was most sadd & lamentable was, that in 2. or 3. months time halfe of their company dyed, espetyally in Jan: & February, being y^e depth of winter, and wanting houses & other comforts; being infected with y^e scurvie & other diseases, which this long voyage and their inacomodate condition had brought upon them; so as ther dyed some times 2 or 3. of a day, in y^e foresaid time; that of 100. & odd persons, scarce 50. remained. And of these in y^e time of most distress, ther was but 6 or 7. sound persons, who, to their great commendations be it spoken, spared no pains, night nor day, but with abundance of toyle and hazard of their owne health, fetched them woode, made them fires, drest them meat, made their beads, washed their lothsome cloaths, clothed and unclothed them; in a word did all y^e homely and necessarie offices for them w^{ch} dainty & quesiie stomacks cannot endure to hear named; and all this willingly and cherfully, without any grudging in y^e least, shewing herein their true love unto their friends & bretheren. A rare example & worthy to be remembered. Tow of these 7. were Mr William Brewster, ther reverend Elder, & Miles Standish, ther Captein & military comander, unto whom my selfe, & many others, were much beholden in our lowe & sicke condition. And yet the Lord so upheld these persons, as in this general calamity they were not at all infected either with sickness, or lamnes. And what I have said of these, I may say of many others who dyed in this generall visitation, & others yet living, that whilst they had health, yea, or any strength continuing, they were not wanting to any that had need of them. And I doute not but their recompence is with y^e Lord."—*The Bradford History of the Plymouth Plantation.*

In our reminiscent moments, when we dwell upon the great advances medicine and surgery have made in the last few decades, we often lay too much stress upon our "science" and upon the remarkable labors of our colleagues, and too little upon some less obtrusive colaborers who are never heard in public urging their claims for personal recognition and priority, and yet without whose efficient collaboration the wheels of progress would have been sadly retarded if not stopped altogether.

Chief of these helpers are the nurses. They save the lives of many doctors every day by assuming responsibilities unknown to their predecessors, and so robbing the work of its harassing wear and tear. And who can calculate how many patients' lives are saved by the alert trained mind ready to recognize danger in its uttermost outposts and so able to summon timely aid. And yet for this very reason because we are so dependent upon these noble helpers in our work we should utter a warning and enter a plea for still higher and nobler ideals in their work.

The trouble with the rank and file of our nurses is that they are spoiled in their training, for the one great dominant impulse of the true nurse, old-fashioned as well as new and trained, should be the tender love of the sick and suffering, a sense of having a mission in the world only rightly fulfilled when with warm heart and skilled hands lifting some little bit of the world's weight of woe.

We have often thought that each training school should have a chair on the humanities, continually emphasizing to

the nurse the emotional, humane, and religious side of her calling. So true is this that we verily believe that without this dominant impulse no woman has a right to enter the sickroom, any more than an unconverted man has a right to enter the pulpit, or a blind man to be a painter. All the scientific superstructure which can be piled on cannot make up for this awful deficiency in their foundation.

And yet a chair, a formal lectureship, would never make up the lack of it, for one cannot have a professor to inspire affection any more than one can buy affection in the market. It rests after all in the head of the scholar; she is the woman by force of daily example, by precept and practice, to see that this tenderness is in the women she selects for the course, and to see that no lines of training are followed which will tend to repress this essential element.

It is the testimony of a great surgeon that we see too much science (so-called) and too little regard for the divine calling in almost all our training-schools. "When I come to seek for nurses in my private practice, I find the woman with a true calling is rare indeed." Our training schools, some of them, are arctic in their temperature and their influence, and the influence of chief nurses seems too frequently to look to the murder of a girl's natural affection and tenderness. But the fault not seldom lies at our own profession's door. All praise, then, is due to the model hospital in Waltham, Mass., where humanity is made the chief issue, where the woman first gains her training among the poor in private practice and has every inducement to develop the affection in a sympathetic personal relationship thus established before entering the hospital mill.

Let us have science and let us have humanity, but let us not have science without humanity—i. e., the love and devotion which filled Florence Nightingale's heart and without which there can be no true and successful nurse.

Aneurysm—Ligation and the Tufnell Treatment.—E. R. Edson (*University Medical Magazine*, April, 1900) reports a case of aneurysm of the left carotid in a negro man 32 years of age. The carotid was ligated about the aneurysm, about 2 months after the first symptoms appeared. The symptoms were ameliorated, but pulsation continued, the aneurysm evidently extending toward the aorta. About 3 months after the ligation, the patient was put upon the Tufnell treatment. This was continued for 75 days, the tumor gradually growing smaller, and finally disappeared altogether. Almost a year later there was still no visible trace of aneurysm, but a nonpulsatile, thoracic bulging had developed. This was 2½ inches in diameter, and on a level with the second rib. It had pressed upon the left phrenic nerve, paralyzing the left vocal cord. Vertigo and dizziness followed the ligation, and still persist. [M.B.T.]

Amputation of the Leg by Cocainizing the Spinal Cord.—William E. Lower (*Cleveland Journal of Medicine*, March, 1900) reports the amputation of a leg without general anesthesia, but by cocainizing the spinal cord. The patient was a man, 64 years of age, and suffering from diabetic gangrene. With a long needle attached to an aspirating syringe 2 drams of a one-fifth of 1% solution of cocain were injected into the spinal canal in the space between the last dorsal and first lumbar vertebra. In 3 minutes there was complete anesthesia of both feet and legs. The amputation was performed immediately and the patient felt no pain. In 20 minutes sensation was restored. At no time was motor power completely lost. There was no shock, as all afferent impulses were abolished. The pulse varied from 68 to 72 during the time of anesthesia. The patient suffered from headache and a tendency to fever and delirium the next day after the operation. After that the patient made an uninterrupted recovery. [M.B.T.]

Reviews.

Twenty-third Annual Report of the Board of Health of the State of New Jersey and Report of the Bureau of Vital Statistics. 1899. Trenton, N. J.: MacCrellish & Quigley, 1900.

This volume contains much that is of local and not a little that is of general interest. It would be impossible to discuss all of the subjects with which it deals, although many are of no slight importance. The report shows that the New Jersey State Board of Health has not relaxed its vigilance in all that pertains to the prevention and the eradication of disease.

Home Nursing: Modern Scientific Methods for the Care of the Sick. By EVELEEN HARRISON. 8vo, pp. xi, 235. New York: The Macmillan Co., 1900. Price, \$1.00.

The subject-matter of this serviceable little volume is considered in 10 chapters, to which is added an appendix dealing with diet in disease and in convalescence, and recipes for invalid cooking. The book has been prepared especially for domestic use, although even trained nurses will find in it much desirable information, set down in an interesting manner. Binding and printing are neat and attractive.

Transactions of the American Pediatric Society, Eleventh Session, Held at Deer Park, June 27, 28, and 29, 1899. Edited by FLOYD M. CRANDALL, M.D. Vol. XI, pp. 252. Reprinted from the *Archives of Pediatrics*, 1899.

It would be difficult to make a selection from among the 28 papers contained in this volume for brief review. Quite all of them contain something of interest and instruction, and all have previously been published. The President's address on "Methods of Instruction in Pediatrics" illustrates the somewhat stepmotherly treatment that pediatrics has received in the medical schools, a branch of knowledge in which the recent graduate should be especially qualified.

The Annual of Eclectic Medicine and Surgery. Edited by JOHN V. STEVENS, M.D. Vol. 8, Embracing the Papers and Proceedings of the Various State Eclectic Medical Societies for the Years 1897 and 1898. 8vo, 533 pages. Cincinnati, O.: The Scudder Brothers Company, 1900. Cloth, Price, \$2.00.

This volume contains a selection of "the good and valuable papers" presented before the meetings of the various Eclectic State Societies during the period that it covers. As may be understood, the essays vary widely in all inherent qualities and it would be invidious to select any one or several for consideration. Even superficial scrutiny, however, discloses a willingness, if not a desire, to eliminate sectarian distinctions that bodes well for the future. Sectarianism is incompatible with science, and the true medical man will avail himself of any therapeutic measure that is capable of subserving his purposes of prevention, cure, or alleviation as related to disease.

Transactions of the Chicago Pathological Society, From May, 1897, to June, 1899. Vol. 3, pp. 553. Chicago: American Medical Association Press, 1900.

This volume is an indication of the really good work that a serious minded medical society can do. There is, further, such a charm in the demonstrative character of the proceedings of a society devoted to pathology that interest never lacks, and although the practitioner may miss from the communications presented formulas and directions for treatment he can easily appreciate that he is the better clinician for being familiar with the conditions responsible for aberrations in function that he is called upon to relieve and whose progress toward recovery it is his duty to aid.

The papers in this volume are arranged in accordance with their relations to anatomic and physiologic systems, and the volume makes a satisfactory and valuable publication. It is, however, a fair question whether a better purpose were not subserved by more frequent and more prompt publication in small fasciculi as is the custom with at least two important medical societies.

The Ophthalmic Patient. A Manual of Therapeutics and Nursing in Eye-Diseases. By PERCY FRIEDENBERG, M.D., of New York. New York: The Macmillan Co., 1900. Price, \$1.50.

In these 312 pages the author treats in a very interesting way of the various procedures and appliances of ophthalmic nursing, the technic of operative assistance, and the nature and use of remedies used in the treatment of eye-diseases. The style is somewhat heavy for nurses who have little or no occasion to know what meiotics (spelling entirely new) and cyclotonics are. Also, the scientific spelling is not in line with modern ideas, but these are minor points. The volume is full of excellent hints to internes and beginners in ophthalmology, and this will probably be the field in which it will find its greatest usefulness. It must in all justice be said that no skilled ophthalmologist could fail to profit by careful reading of the book, but as we have said, its greatest service will be to the ophthalmic student and perhaps to nurses who contemplate giving themselves up to nursing "the ophthalmic patient."

International Clinics. A Quarterly of Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession throughout the World. Edited by HENRY W. CATTELL, A.M., M.D., Philadelphia, U. S. A., with the Collaboration of JOHN ASHHURST, JR., M.D., LL.D., and CHARLES H. REED, M.D., and JAMES T. WHITTAKER, M.D. Volume I. Tenth series, 1900. Philadelphia: J. B. Lippincott Company, 1900.

This volume contains 4 papers on disease in the Philippines and camp-sanitation, 4 on therapeutics, 4 on medicine, 1 on neurology, 3 on surgery, 1 on pathology, 1 each on diseases of the eye and ear, together with a review of progress in the various departments of medicine during the year 1899. It will be seen there is something of interest for all medical men. Some of the articles are most timely and of especial value, and to this end the illustrations contribute in no small degree.

A Practical Treatise on Materia Medica and Therapeutics. By ROBERTS BARTHOLOW, M.A., M.D., LL.D., Professor Emeritus of Materia Medica, General Therapeutics and Hygiene, in the Jefferson Medical College of Philadelphia, etc. Tenth edition, revised and enlarged. 8vo, pp. xxxii, 866. New York: D. Appleton & Co., 1899.

Bartholow's Therapeutics has so long been a standard publication that an extended review of it is unnecessary. Instead of being pushed aside by newer works upon the subject, it has maintained its place in the confidence and regard of the medical profession. The present edition, the tenth, differs chiefly from the eighth and ninth by the incorporation of new matter which the progress in pharmacology has made necessary. Most of the newer remedies are synthetic products which manufacturing chemists have introduced, often with extravagant claims. The author selects for description those he considers the more important and useful. His discussion of their therapeutics is in the main satisfactory, though the volume has been increased in size by only 45 pages. Those who examine this last edition will find in it the best of that which is old and, for the most part, also the best of the newer remedies, the value of which is not so well established.

Forty Years in the Medical Profession: 1858-1898. By JOHN JANVIER BLACK, M.D., Fellow of the College of Physicians of Philadelphia; Member of the Delaware State Medical Society, etc. 8vo, pp. 498. Philadelphia: J. B. Lippincott Company, 1900.

The 40 years included in the period covered by the narrative in this autobiographic sketch have witnessed many changes in the science and art of medicine and to the more important of these some brief reference at least is made. No life is wholly free from noteworthy events, but that of any medical man will contain enough to furnish, in suitable hands, material for stories really more strange than fiction. Dr. Black has woven together an interesting account of many things that have transpired in the course of his professional career, and his hope that it will help to while away pleasantly a leisure hour will easily be realized.

Injuries to the Eye in Their Medicolegal Aspect.

By S. BAUDRY, M.D., University of Lille, France. English Edition Revised and Edited by CHARLES A. OLIVER, A.M., M.D. 161 pages. Philadelphia: The F. A. Davis Company, 1900.

This monograph on the medicolegal aspect of ocular injuries shows that there are many fields for medicoliterary venture as yet unexplored. There is nothing just like the above work so far as we know. And it is timely, for, with the tremendous multiplication of corporations, there has sprung up in the mind of the average citizen the idea that injury in any of the public corporate or municipal services means the recovery of damages often out of all proportion to the injury. The volume before us cannot but help as an authority to lend weight to the medical expert's testimony and thus conduce to an equitable adjustment of such cases. The subject is exhaustively treated and covers almost all possible eye-accidents and their consequences. The work of the translator has been well done, while the adaptation of the "Chapter on Medicolegal Testimony" to the Courts of the United States will greatly add to the value of the volume. This chapter alone is well worth the price of the book and might, with profit, be practically committed to memory by any specialist about to be called as a medical expert.

Diseases of Children. By ASHBY and WRIGHT. Fourth Edition. Edited for American Students by W. P. NORTHRUP, M.D. Publishers: Longmans, Green & Co., London, England.

This excellent treatise on the diseases of childhood has been before the medical public since 1889, and in its various editions has enjoyed an increasing and well-deserved popularity. The book is unique in being written by a medical man and a surgeon. The subjects treated of are chiefly medical, but whenever there is an opportunity of viewing them from a surgical standpoint, this has been done and well done. There is also, especially in this fourth edition, a somewhat complete consideration of certain surgical subjects, some of which, to judge from the illustrations, are those of adults, and scarcely pertinent, but the whole constitutes a most suggestive and useful book for practical consultation. There is displayed throughout the work a large measure of research, and in a larger degree eminently practical clinical observations. The illustrations are numerous and very good, and many new ones have been recently added, chiefly skiagraphs. Among the abundant excellencies of the book it is difficult to find anything to criticise, especially since the additions by the American editor furnish some important data on laboratory milk mixtures, and many references to the work of American observers, and quite an extensive appendix containing suggestions as to food and medicines, quite important for the American reader, who is accustomed to a much better presentation of therapeutic measures than is ordinarily to be had in foreign books, especially English. The chapter on diseases of the kidneys leaves something to be desired, and is by no means as complete and modern as other portions of the work. This is especially obvious in the description of urinalysis. The

book is eminently symmetrical and valuable, and to be highly recommended as a working manual. Certain subjects could well receive some larger elaboration, and it would be possible to spare the mention of certain others, especially of a surgical nature, which might better be in a separate volume and treated of more at length.

Diseases of the Intestines. By MAX EINHORN, M.D. New York: William Wood Co., 1900.

Several valuable contributions upon diseases of the intestines have been made to Systems and Encyclopedias of Medicine, but Einhorn's book is the only monograph on the subject published in America that has come to our hands. This work consists of 12 chapters; the first of which treats of the Anatomy and Physiology of the Intestines in a complete manner and numerous good illustrations embellish this portion of the book. In the second chapter a pleasing prominence is given to "Examination of the Feces," a matter that receives too little attention at the hands of the majority of practitioners.

In speaking of methods of treatment artificial alimentation is said to be carried out in two different ways, rectal and subcutaneous; for use beneath the skin olive oil and saline solution are the only substances recommended as of practical value.

The consideration of chronic intestinal catarrh is very practical and it is with regret that we notice the omission of some important matters under the etiology of the affection, for instance, the oft-repeated functional failure that results from an overwrought nervous system and in time may lead to structural defect; also the overtaxation of the intestine caused by the condition of the stomach described by Einhorn as *Achyilia Gastrica*. It would emphasize these points to include them under this heading. The fourth chapter is devoted to Dysentery, and its amebic origin is particularly dwelt upon. The disease is considered as an entity, with amebae the cause in all cases of whatever variety; thus a departure is taken from the common method of separating amebic from other forms of dysentery. This is simply a question as to the point of view regarding what should, or should not, be considered dysentery.

In the consideration of duodenal ulcer the etiology of the affection is given quite fully, but does not include the neurotrophic phase that, after all, is the probable initial cause of so-called peptic ulcer of the stomach and duodenum. The other varieties of intestinal ulcer are fully dwelt upon. A very practical chapter upon hemorrhoids contains some new prescriptions and the surgical treatment is discussed at considerable length.

The chapter upon appendicitis is most commendable, being thorough, scientific, and up to date. The diagnosis of appendicitis that has spread to the tissues surrounding the appendix and has there given rise to a purulent peritonitis, is aided greatly by finding a leukocytosis, but Dr. Einhorn makes no mention of that point. A review is not the place to enter upon a discussion of appendicitis, but we certainly have been guided toward prompt operation, in cases exhibiting only mild symptoms, by the discovery of a decided leukocytosis, and the results of the operation proved that they were timely. Exact directions for medical treatment of appendicitis are given, and opium is recommended as the remedy *par excellence*. The surgical treatment of the disease is debated in an interesting manner and makes clear the fact that the author is not in favor of too early or hasty operative interference at the first suggestion of appendicular trouble.

Intestinal obstruction is exhaustively treated and an interesting account of the "Nervous Affections of the Intestines" follows, in which they are classified into (1) motor, (2) sensory, and (3) secretory neuroses. Constipation is here classed and is considered in an admirable manner; much stress being laid upon mechanical measures in its treatment.

The much discussed disease, Membranous Enteritis, is considered in an excellent manner and the work ends with a chapter upon intestinal parasites.

It is a book deserving of high praise and will be of great value to all internists.

The publishers have done very good work, and the volume is convenient in size.

Special Article.

THE SURGEON IN THE NINETEENTH CENTURY.¹

Address in Surgery at the Annual Meeting of the British Medical Association at Ipswich, August, 1900.

By FREDERICK TREVES, F.R.C.S.

Surgeon-Extraordinary to H.M. the Queen; Surgeon-in-Ordinary to H.R.H. the Duke of York; Consulting Surgeon to the London Hospital.

This century has been without a parallel in the history of human culture, and so far as the art of surgery is concerned has embodied an advance in principle and in practice which has been no other than revolutionary. I do not propose to attempt a review of the progress of surgery during the last hundred years. That work has been already done by abler hands. I would venture rather to deal with the progress of the surgeon himself during this period, and with the advancement of the individual as an exponent of a grave profession.

There is little difficulty in fashioning a picture of England as it was 100 years ago. A sympathetic literature has left us with ample records of the men and women of the time and of the scenes they moved among. These records are rich with the littleness of personal affairs and are made living by the very gossip and petty commentaries of those who constituted society when the century was young. The life in England then was largely life spent in the country, in sleepy villages, and in sober, self esteeming county towns. The conditions were yet immature which led men to herd together in ever-extending cities and to swarm around oases of blackened chimneys and restless furnaces.

Education among the masses of the people was a matter of little account, and was to a great extent actually nonexistent. The average man of the middle class was quite content with a degree of learning which would do little more than satisfy the demands of a modern School Board.

As to the surgeon in those days, he was but a sorry element in social life. In the great towns and cities there were esteemed practitioners of surgery who were eminent by reason of their scientific work and their successful practice, but their numbers were few. At the commencement of the period under notice London was the center of surgical activity, and the prominent exponents of the art at that time were John Abernethy, Henry Cline, Sir William Blizard, Sir Everard Home, Sir Astley Cooper, William Lawrence, and Charles Aston Key. The great John Hunter had died in 1793, having accomplished a work which marks an epoch in British surgery. In the provinces the most conspicuous surgeons were Edward Alanson, of Liverpool, and William Hey, of Leeds, while in Edinburgh the position of the leading operator was held for many years by John Bell. A little later in the century we find among the names of prominent men in England those of Sir Charles Bell, Sir Benjamin Brodie, and the ingenious and learned Benjamin Travers.

At the beginning of the century, surgery on the Continent was represented by such men as Sabatier, Deschamps, Boyer, and Larrey in France, Scarpa in Italy, Langenbeck, Cnelius, and Diefenbach in Germany, and Warren and Physick in America.

The surgeon or common practitioner in the village and town in these early days has been depicted by many writers. Possibly the most precise of these was Smollet, who was himself in turn an apprentice, an assistant, a surgeon's mate, a practitioner, and a graduate in medicine. Smollet died in 1771. The account he has furnished of the leech of his time is tolerably discouraging. We find him an ignorant, illiterate, sordid creature, not above the allurements of money-grabbing, and not without suspicion of dishonest practices and of a leaning towards the bottle. He was to a large extent a mere retailer of physic, and in the public eye he ranked with the quacks and nostrum-sellers with whom he competed. There was probably some excuse for a writer who, in a discourse in the *New Monthly Magazine* for 1828, speaks of the general body of surgeons as a "cringing pulse-feeling race." Smollet's description could not have been true of all his brethren, and there is no doubt he wrote with the bitterness of an unfortunate experience. Still, there can be little question that

Launcelot Crab represented a type not yet extinct when the century began, and he must be taken as the forerunner of the cultured and esteemed general practitioner of the present day.

1.—THE SURGEON AS AN ADVISER.

In noting the advances made by the surgeon during the century, the first matter which may be dealt with concerns his position as an adviser to his patient. In reviewing this subject, one cannot fail to be immediately impressed by the paramount influence which exact knowledge—or a *fortiori* the want of exact knowledge—has had upon the attitude of the medical profession.

It is obvious that the progress of any science is to be measured by the amount of absolute truths which may have been accumulated at a given time. The lack of knowledge, the mass of things unknown, represent only a void to be filled. In the development of the science of medicine the element of the unknown has not remained so negative a factor, but has, on the contrary, proved to be a stimulus for a very luxuriant invention, the products of which have been tabulated as facts.

There is no science outside our own in which there has been, during the stages of development, such an extreme disproportion between the amount of knowledge professed and the amount proved ultimately to be exact and sound. As an example of this may be cited the "humoral" system of pathology which, in spite of its ancient origin and its more or less obvious foolishness, held a position in Medicine for centuries, and struggled on, as a distorted and dying creed, even into modern times. This system, in its barest features, asserted that four cardinal humors occupied the human body, and that practically all diseases, and certainly all tumors, were due to disorders of certain of these fluids. The pathology of this system was precise, dogmatic, elaborately classified, and full of detail. Upon it all treatment was founded, and yet the whole of this precious system was a daring fiction, an ingenious fancy, the product of an impudent and unscrupulous imagery.

The reason of all this lies more with the sick man than with the man of medicine. The sick man requires absolute and exact knowledge from his doctor. He will accept neither possibilities nor doubts nor confessions of ignorance. He will accept such from his lawyer and from his man of business, but not from the man who attends him in illness.

It is no matter of wonder that in the past the physician has made good by fiction what he lacked in fact. The demands of the patient have been hopelessly beyond any powers of supply, and the deficiency has been furnished by the products of invention. It would seem that the less the man of medicine knew the more he invented, and the more diligently he hid his little light under the bushel of a ceremonious and mystery-making treatment. The judicial wig, the academic ruff, the gold-headed cane, the reflective snuff box, and the Socratic air all made an effective covering for the few poor bones which formed the skeleton of his knowledge.

It thus happens that a good deal of the pretense and humbug with which medical practice has been associated in the past has been forced upon the practitioner by the demands of unreasoning people. With such people the surgeon, in the early part of the century, had more largely to deal than he has to do at the present day, and yet his stock of knowledge could seldom meet the demands even of the reasonable. Hereby it came to pass that the puzzled man of medicine had to repudiate his ignorance, had to concoct such explanations and to construct such pathologies as could meet the sick man's inquisitiveness, and at the same time give a semblance of reason to an empirical and tawdry system of therapeutics. His utterances were tangled and confused by conceits of his own invention. A false attitude towards his patient was unconsciously forced upon him, and the folly of his pretense to an unattainable learning was apparent to all but the simplest. As an adviser, therefore, he spoke not as one having authority, and his position intellectually is well illustrated by the endless lampoons and caricatures to which he was publicly subjected.

The surgeon of the present day, as an adviser, is in a position which is so greatly improved that it could hardly have been imagined by his forebears of 100 years ago. He has in the first place to deal with a more enlightened public, with patients whose education to a large extent enables them to

¹ Published from advance sheets by courtesy of the British Medical Journal.

appreciate the nature of scientific problems, and with whom it is possible to discuss difficulties, and to own to lapses of information.

In the second place, the additions made to surgical lore have been so substantial that in many departments surgery has reached to the status of an exact science. There is indeed no longer need to call upon invention to supply such gaps as still indicate the unknown. An intelligent patient is satisfied with the assurance that practically nothing at present is known of the nature and causes of cancer. Such assurance is at least as valuable as the information provided at the beginning of the century, when the inquirer would have been told that cancer was "a diseased hardness," or a "scirrhous degeneration."

We have perhaps not quite shaken off the poor vestments of mummery with which ignorance was clad, nor rid ourselves of forms of speech which still pass current for sense, but which are little more than sounding brass and tinkling cymbal. We speak assuredly of the "constitution" and of "states of the system" and of the "supporting of the system." We sanction such terms as "poverty of blood," "diminished vitality," and "sympathetic inflammation." We propose to believe in "tonics," in medicines the swallowing of which will give strength, in "galactagogues," in "alteratives," in "astringents," and in "cooling physics." We profess, moreover, to "strengthen the lungs" and give "tone to the stomach."

The modern surgeon can well afford to dispense with all this empty verbiage, since he can base his opinion upon demonstrated facts and can express it in plain words, free from any of the embellishments of a literary masquerade. For many reasons this is well.

2.—THE SURGEON AS A MAN OF LEARNING.

The surgeon at the commencement of the century appears to have lacked most of what we now consider to be the essentials of the art, and we can only view with amazement the scantiness of his learning and the poverty of his equipment. He knew little more of inflammation than that it was represented by swelling, heat, redness, and pain. His knowledge of the causes of inflammation and of those dangers which follow upon open wounds was scarcely in advance of that professed in the days of Hippocrates. He had no glimmer of the possibilities of aësepsis. He had no anæsthetic, no hypodermic syringe, no clinical thermometer, and no practical means of investigation in clinical chemistry. The very name bacteriology did not exist, and the treatment of diseases by prepared serums would have appeared to him as wild as the wildest therapeutic dream of ancient days. Although vaccination had been introduced in the last year of the eighteenth century, the magnitude and nature of the principle it involved had not been appreciated.

The microscope as an aid to diagnosis played no part in the equipment of the surgeon. He had neither laryngoscope nor ophthalmoscope, and his acquaintance with otology, skin affections, and the diseases of women, was at the best rudimentary and indistinct. He had only rude medieval orthopedic appliances, and he knew nothing of the lithotrite nor of the array of instruments which are now in daily use in connection with ophthalmic, laryngeal, cranial, and abdominal surgery. It would seem, indeed, that there was little for him to do but to open abscesses and sow the seeds of chronic septicæmia, to excise tumors of the structure of which he talked much and knew little, to amputate limbs for diseases he could not mend, and to draw blood whenever doubt existed as to what was best to be done.

Conservative surgery was not understood, and was certainly not practised, and plastic methods of operation had no place in treatment.

Lord Thurlow, in speaking against the Surgeons' Bill in the House of Lords in 1797, declared, with some basis of truth, that "surgeons in this country are not respectable men, their pretensions are unjust and illegal, because they are not a scientific body."

In 1800 a man could practise as a doctor without passing an examination of any kind. Indeed, one itinerant practitioner is reported to have assumed the title of assistant surgeon on the ground that he had served an apprenticeship to the crutch-maker of a hospital. The examination for the diploma of the Royal College of Surgeons was by *ritu voce* only. There was no examination of patients, and no dissection of the subject.

Candidates were required to produce evidences of apprenticeship, of attendance upon anatomical and chiralurgical lectures, of having performed dissections, and of having attended the practice of a recognized hospital for a period of six months.

In 1813 the period of compulsory attendance at a hospital was raised to one year. The standard of knowledge, however, does not appear to have risen in corresponding proportion, for in 1822 the then president, Sir William Blizard, felt called upon to address the Court of Examiners on certain "tokens of remissness in teachers, and of inattention in students," which had been forced upon his notice. He regrets that candidates are commonly ignorant of the situation of nerves and bloodvessels, of the disposition of the muscular fibers of the heart, gullet and stomach, and of the diameters of the intestine. He further adds that "the deficiency of candidates in physiological information is far more remarkable," and enters into such detail as the following: "Often do we find them," says the president, "ignorant of the reasons why the ribs in inspiration are, from their figure and muscular connection, moved upwards and outwards, of the systole and diastole of the heart, of the process and intention of respiration, of the nature and distinction of the pulse, of the distinct offices of divers muscles, of the figure of the lens and uses of the humors of the eye in vision."

He concludes by deploring that there is a "correspondent darkness of mind relating to the symptoms, seat, causes, and rational treatment of diseases and injuries," and furnishes a catalog of items with which candidates do not appear to have been commonly conversant, although the list presents such matters as the signs of fractures and dislocations, the symptoms of compression and of inflammation of the brain, the consequences of fractured rib, and the rationale of the symptoms of hernia.

At the commencement of the century there was, indeed, no systematized medical education. The training of the surgeon was paltry, casual, and inefficient. His preliminary education was miserably meager. It was necessary that he should be able to read and write and pretend to some smattering of Latin. He became an apprentice, and, in that menial capacity, gleaned what he might from his master and from attendance upon sundry lectures. So far as hospital practice was concerned, his attitude as a learner was well expressed by the phrase, "He walked the hospital." The institutions which he thus attended for a period of six months were in a state of rude squalor as regards administration, sanitary arrangements, and nursing, and well deserved the abuse which was lavished upon them.

3.—THE SURGEON AS AN OPERATOR.

During the nineteenth century the surgeon, as an operator, passed through a rapid metamorphosis, and has now reached at least the level of the unexpected. It may have been supposed that there is little to be learned in the way of using a knife which had not been learned during a period of over eighteen hundred years, for there were surgeons before the Christian era. Yet time has shown that even in 1800 there was a technic in operating which was as little like the technic of to-day as are the slashes of a cutlass when compared with the studied movements of a foil. It may have been surmised that twenty centuries would have exhausted the methods by which a limb could be cut off. Yet in 1800 modes of amputation were in vogue which are now regarded as uncouth. It cannot even be said that the commencement of the century saw in use a ready and efficient means of checking bleeding, although that measure represents the most elementary of the surgeon's duties.

The operator of olden times certainly possessed many qualities which are now falling into abeyance, and which cannot pass away quite unregretted. The success of his craft depended largely upon his daring, upon the alertness of his eye, the steadiness of his nerve, and the rapidity of his movements. He stepped into the arena of the operating theater as a matador strides into the ring. Around him was a gaping audience and before him a conscious victim, quivering, terror-stricken, and palsied with expectation. His knife was thrust through living flesh and acutely-feeling tissues, and the sole kindness of his mission was to be quick. In spite of moans for mercy from gagged lips the knife had to move on its way steadily, and, undeterred by struggles and bursts of hemorrhage, the blade must needs pass without faltering or sign of hesitancy.

There is less need for such qualities now. The dramatic element in surgery has gone with the men who unconsciously fostered it. The operating theater of the present day has lost its horrors, and has changed from a shambles to a chamber of sleep. The surgeon's hand can move with leisurely precision, and theatrical passes of the knife are favored only by those who have not yet learned that mere brilliancy is no measure of success.

It may be that the present-day surgeon is a loser in that he has less need for those dashing qualities which were essential to the operator before the days of anesthetics; but, on the other hand, he has gained much in the direction of the sympathetic handling of his patient and in the culture of gentleness.

It is little wonder if the older surgeon became rough and stern, if his sense of feeling became dulled, and if the sympathetic side of his nature suffered some suppression. Indeed, contemporary accounts are apt to represent the operator of preanesthetic times as rough almost to brutality, and as coarse both in his conduct and in his utterances. His language, it would appear, savored of the cockpit, and the hasty flourishing of his knife led occasionally to unintended mutilations.

Within the compass of some thirty years the whole state of affairs has changed. Consideration for the patient and for the patient's sensibilities have become a matter of the first moment, and the operator has learned that his work is best done if done with gentleness and tact, and that haste and bluster, coarseness and coarse handling are out of place around the operating table. A striving after effect at any cost has ceased to be an element in the surgeon's work. Success is no longer to be measured by the number of minutes occupied in the amputation of a limb, but by the state of the patient many days after the measure has been completed. The triumph of the older surgeon was immediate and scarcely reached beyond the arena of the theater. The triumph of the modern surgeon is deferred, and is found in the operation ward and in the convalescent home.

Still, the fact remains that it is easier to be a surgeon of some degree at the end of the century than it was at the commencement, since in the earlier days the qualities needed for success in operating were rare and of a kind not readily to be acquired.

On passing more into detail, one notices that beyond these general changes in the attitude of the operator there have been others which owe their existence to special advances in the surgeon's art. Prominent among these may be named: (1) An improved knowledge of anatomy; (2) a readier method of arresting hemorrhage; (3) the employment of anesthetics; and (4) the introduction of anti-septic measures.

1. *An Improved Knowledge of Anatomy.*—Among the surgeons of the early part of the century there were many competent anatomists, and not a few who could lay claim to be deeply versed in that science. Among the latter were such men as Astley Cooper and William Lawrence. Still, in the education of the average surgeon the study of anatomy did not play a prominent part. Anatomy was largely taught by means of public demonstrations. The teacher dissected and the student looked on, much as he did in the days when Rembrandt's great picture of Nicolaus Tulp and his pupils was painted. The knowledge required was scant and superficial and had little practical basis, and no methods of teaching existed which can in any way compare with those in vogue at the present day. The science of anatomy was well advanced at the commencement of the century, but it was not taught to the common student. *Quain's Anatomy*, first published in 1828, contained a very sound account of the human body, although the whole work was then represented by a single small volume of 700 pages which was without illustrations.

The facilities for acquiring a practical knowledge of anatomy were not only few, but were hampered by many sordid difficulties. Anatomical schools were regarded with disfavor and were actively discouraged. They were viewed with unconcealed suspicion by the public, and were surrounded by a ghoulish romance in which rifled graves and unseemly dealings with the hangman played a pungent part. Indeed, the teacher in an anatomical school found himself involved in a squalid and disreputable traffic, very ungenial to any earnest man of science.

Among the many qualifications needed for success in

operating, a practical knowledge of anatomy as acquired by repeated dissection, is conspicuous. Such knowledge as the surgeon needs is to be learned not from books but from the patient use of the scalpel and forceps. The dissecting room is the surgeon's nursery. The tissues of the body are the material with which he works, and he must needs know them as the sculptor knows the marble he chisels and the potter the clay he moulds.

It is no matter of surprise that the older surgeon often lacked confidence in operating, that he failed in initiative, and clung only to formulated methods, and that a departure from accepted lines was attended with fear and hesitancy. Ignorance encouraged in the rash heroic passages of the knife and in the timid an overcautious and dangerous fumbling. And as to this it is probable that in preantiseptic days as much ill attended the nervous fingers which were creeping clumsily into the unknown as followed the reckless operator who essayed to draw his bow at a venture.

2. *A Readier Method of Arresting Hemorrhage.*—At the commencement of the century the means employed for the control of bleeding were numerous, and were represented by such familiar measures as the ligature, the suture, styptics of many kinds, and the actual cautery. In applying the ligature the vessel was picked up by forceps and tied as at the present day. The instruments used were those of Dieffenbach, Assilini, and Liston. The older types of instruments were not readily applied, or at least required time in their adjustment. The bleeding from the vessel was not necessarily controlled by the forceps when in position. The general rule in amputation was to apply a tourniquet and to ligature the individual arteries after the limb had been removed. In the excision of tumors the practice was recommended of securing each vessel as it was divided.

When it is remembered that operations were carried out without anesthetics, it will be understood that the older surgeon had an absolute terror of bleeding, and was driven to undesirable shifts to avoid the need of facing it. He was indeed a coward where hemorrhage was concerned, and there was reason for alarm when a conscious patient was struggling and showing signs of exhaustion, and when the means for staying the stream of blood were slow of application.

We find, then, that hemorrhage was expected, and that a liberal loss of blood was considered to be a necessary adjunct to every major operation. Tourniquets were employed freely and with considerable harshness. Raw surfaces were bathed with styptic solutions which were often destructive in their action or at least opposed to primary healing. The actual cautery with which to sear the bleeding area was in some request, and every well equipped operating theater kept its stove and its cautery irons in constant readiness.

The least pleasant evidence of the surgeon's dread of hemorrhage and of his inability to deal with it was afforded by the treatment of certain nevi in infants and children. These growths were strangled by ligatures which slowly cut their way through the skin and the neoplasm, assisted by a benevolent process of suppuration. A painful ingenuity was expended upon amplifications of this measure, the cruelty of which was but little mitigated by the introduction of chloroform.

Allied to this procedure was the *écraseur* of later date. Its invention was due to Chassaignac, and it was freely used in England until quite recent times. It was employed for the removal of growths of various kinds, but its most baneful employment was as a means of excising the tongue. It is scarcely to be believed that within the period of the introduction of anesthetics the tongue has been torn out of the mouth by means of a loop of hemp or wire which strangled it as its root.

The *écraseur* will remain in the archives of surgery as the insignium of the incompetent and the timorous, and will stand out as a blot in an otherwise bright period of progress and enlightenment. The shadow of this medieval instrument has been slow to fade, and as the ovarian clamp and the *sérénau*, it clung about the confines of reasonable surgery and hindered the development of the operations of ovariectomy and excision of the uterus.

At the present day the surgeon has little dread of hemorrhage, and the confidence he possesses is based upon good grounds.

In the first place, he makes larger use of the precautionary ligature of vessels. It has become a commoner practice to

apply a temporary or permanent ligature to a main artery before a part supplied by that vessel is excised. This is carried out frequently in dealing with large and vascular tumors. In removal of the tongue, moreover, an excellent method is that in which a preliminary ligature of both linguals in the neck is carried out. In removing the uterus through an abdominal incision the question of hemorrhage is disposed of by an early ligature of the ovarian and uterine vessels. A further example of this mode of anticipating bleeding is afforded by that method of hip amputation which is known as the anterior racket. Here the main vessels and even the main branches are secured before the flaps are cut, whereas by the older plan the vessels were severed with the flaps and were tied after the limb had been removed.

In the second place, the latter-day surgeon is operating upon an anesthetized patient and can proceed with slowness and deliberation. The importance of this fact in connection with the present subject cannot be overstated. In the instances which have been just cited an excision of the tongue in a conscious patient would be greatly extended by the twofold operation in the neck, and whereas the amputation of the hip by transfixation occupied in able hands but a minute or so, the operation by the anterior racket is tedious and involves relatively much expenditure of time.

Thirdly, the treatment of hemorrhage has been to a remarkable extent simplified, if not indeed rendered complete, by the introduction of the pressure forceps of Sir Spencer Wells. These little instruments represent the most valuable addition which has ever been made to the surgeon's appliances. It is not uncommon in operations of a certain type to have 10 or more pairs of pressure forceps applied to the surface of the wound at one time. This represents a degree of possible bleeding which in the old days when every vessel had to be separately tied, would have been replaced by actual bleeding of a fatal type. No instrument has brought with it so great an assurance of security or has done more to extend the area of safe operation.

3. *The Employment of Anesthetics.*—The value of the anesthetic and the radical and beneficent transformation it has effected in surgical practice call for no comment in this place. The changes that the discovery has wrought in the personality of the surgeon, in his bearing, in his methods, and in his capabilities are as wondrous as the discovery itself. The operator is undisturbed by the harass of alarms and the misery of giving pain. He can afford to be leisurely without fear of being regarded as timorous. To the older surgeon every tick of the clock upon the wall was a mandate for haste, every groan of the patient a call for hurried action, and he alone did best who had the quickest fingers and the hardest heart. Time now counts for little, and success is no longer to be measured by the beatings of a watch. The mask of the anesthetist has blotted out the anguished face of the patient, and the horror of a vivisection on a fellow-man has passed away. Thus it happens that the surgeon has gained dignity, calmness, confidence, and, not least of all, the gentle hand.

Anesthetics have, moreover, greatly extended the domain of surgery by rendering possible operations which before could have been only dreamt about, and by allowing elaborate measures to be carried out step by step.

The introduction of anesthetics has not only developed surgery, but it has engendered surgeons. It has opened up the craft to the many, for in the preanesthetic days the qualities required for success in operating were qualities to be expected only in the few.

In the technic of established operations chloroform and its allies have led to advantageous changes. This is well seen in the case of amputations. In the olden days that method of removing a limb was best which was the most speedy. A prominent position was, on this account, given to the cutting of flaps by transfixion, a long narrow blade being used for the purpose. This rapier-like instrument required great skill in handling, and in the grasp of the feeble it was a fearsome weapon. Muscles were sliced through in such a way that the widest possible section of their substance was often made. Vessels and nerves were, in like manner, cut almost in the direction of their long axes, and the resulting incision gave the maximum area of wounding. At the present day transfixion is abandoned, and the murderous amputating knife has found its way into the museums of the curious. Muscles can now be severed at right angles to their length, or in such

a way as to secure the smallest possible surface of section. Vessels and nerves are cleanly divided in the same manner, and the resulting area of the wound is reduced to a minimum. This difference in methods is vividly illustrated by amputation at the hip-joint.

4 *The Introduction of Antiseptic Measures.*—Of the great work of Lister, and of the introducing of the antiseptic treatment, there is no call to speak at this time. When the century was young the touch of the operator was the touch of a tainted hand; the brain he poured into the wound was poisoned, and he himself undid the good his science strained to effect. It is sad to think that behind the earnest man with the ready knife there stood a shadow which rendered hopeless his kindest effort, and which only too often proved to be the veritable shadow of death.

The change has been great, and its greatness lies in its littleness, for it is bound up with no more than this: that the surgeon has learned to be clean.

The operator of days gone by would have turned with some petulance from the grand simplicity of the counsel to be clean. He ever sought some means of mighty bearing to rid him of the incubus of failure, and, like Naaman of old, he would have hesitated to dip in the Jordan of antisepticism to be free of his leprosy.

The surgeon has not only learned to be clean, but he has become aware of the potency of little things. The demands of the antiseptic treatment have made him minutely careful, distrustful of any aid that he cannot control, and suspicious of any semblance of error.

It is possible that the abandonment of the old easy order of things has been followed by a too slavish devotion to mere ceremonial. The remarkable and extravagant preparations with which some surgeons now approach an operation, the cleansings and the washings which precede the laying on of hands, smack a little of fetish worship, and foster the cult of the surgical Pharisee. On the other hand these performances, this "making clean of the outside of the cup and platter," seem to give assurance, and to render the devotee thankful that he is not as other men.

THE SURGEON IN THE FUTURE.

Circumstances in the tendencies of today foreshadow to some extent what may lie buried in the future. The changes which have swept over the world of surgery have extended the possibilities of the art, and have, at the same time, added a host to the ranks of those who practise it. Some thirty years ago the roll of such as could claim to be accomplished operators was very small. The greater deeds of surgery were limited to cities and the larger towns. The general practitioner seldom took up the scalpel except in minor necessities. Even in London the list of consulting surgeons was meagre. In the hospitals of the metropolis the number of operations performed in the year would be less than is now the quorum for a month.

But here at the close of the century the disposition of affairs is wholly altered. Where there was one surgeon there are now ten, and throughout the breadth of the land and to its utmost limits the work of the operator has extended. The more ambitious performances of surgery are no longer restricted to the great centers, but are carried out in the little town, in the cottage hospital, and even in the cottage itself. The general practitioner is laying claim to operate upon his own patients, and is carrying out his intention in no hesitating manner. The days of the great operator, of the one man to whom all came who could, are rapidly passing away. Indeed, the practice of pure surgery, which was at one time limited to the prominent few, is now becoming common to the many. The man who excels conspicuously as an operator will always attain such eminence as his ability deserves, but the exclusiveness of the practice of operative surgery is quietly vanishing with the century. This change is well. It is a change that is inevitable. The democratic movement is the active power of the day, and that an oligarchy in the community of surgeons should be replaced by an earnest democracy is precisely in accord with the spirit of the times.

In every great change there must—at first, at least—be some undesirable developments, and it is impossible to deny that the wider distribution of the practice of operative surgery may lead to the occasional performance of major operations by men who are not justified, either by experience or by training, in undertaking them. Furthermore, there is,

among the signs of the times, some evidence that the reaction in the matter of operative surgery is to some degree extreme, and that we are in danger of passing from the policy of doing too little to the policy of doing too much. Operations we know were too few in the past, but there is some foundation for the impression that they are occasionally too frequent in the present.

One other matter which looms out of the future will suffice to bring this subject to a close. So many have been the artificial aids to clinical investigation which recent science has introduced that it comes to be a question whether the natural acumen of the surgeon will not deteriorate in proportion as he fails to encourage that particular learning which clings to the finger-tips of all great diagnosticians. That there will be such a decadence is beyond doubt. The loss is to be deplored, for if there be one point of excellence which stands before all in the qualifications of the perfect surgeon, it is bound up in that refined sensibility, that critical perception, that inestimable cunning which lies in the surgeon's touch.

Examples of the direction in which this loss will be felt come readily to mind. A considerable amount of skill, for example, is demanded in the examination of complex fracture, of lesions of deep-seated bones, and of injuries about joints. What was to be learned of these troubles had to be acquired by a tedious manipulation demanding considerable refinement. The surgeon who has now to deal with such conditions can afford to dispense with a prolix examination, and can submit the inquiry to a demonstrator of the Röntgen-rays. The skiagraph, although its value is much exaggerated, embodies substantial gain, but it is to be discounted by the loss of the great element in education which it is slowly replacing.

An obscure tumor—to take another instance—presents itself, and no longer is the surgeon compelled to trust to the acuteness of his inquiry and his patient review of all the physical details of the mass. For what his ready fingers may have learnt can be substituted the findings of the exploratory incision, the trocar, and the aspirator. Here once more an advantage is minimized by a loss.

Or, again, an abdominal swelling is brought under notice. Its features are obscure, but much of the uncertainty of outline can be dissipated by a cultured hand which, with infinite patience and repetition, has learned to construct a reality out of a shadow. It may be said that it is needless to persist in bringing this much-elaborated means of inquiry to further perfection since the problem is at once to be solved by an exploratory laparotomy. By such little operation a great advantage is gained, but an opportunity to add to one of the most refined forms of learning is lost. The value of the exploratory incision is beyond question, but among the signs of the times it is impossible not to notice a tendency to resort too readily to this means of solution. The Gordian knot, according to the legend, was ultimately cut, and it is a question whether the sum of human ingenuity would not have been substantially increased if attempts to untie the noose had been more diligently persisted in.

In another example, let it be supposed that a suspicious ulcer presents itself for diagnosis. In such case it is well to devote time to a precise and tedious inspection of its edges and to a careful tactile examination of its base, and to check what is discovered by results laboriously gained from like inquiries? Is it not simpler to take a scraping of the affected surface and to submit it to a microscopist, and to thus be spared a method of examination which, although it may not give final results, yet represents an opportunity of furthering a priceless accomplishment?

Finally, there are cases which present symptoms hard to interpret at any superficial inquiry. Is it worth while in such to undertake an exhaustive critical research and to submit the whole to a trained judgment? The quest would no doubt develop habits of observation and powers of weighing evidence; but the process is slow, and an inquiry carried out in a bacteriological laboratory will clear up all doubts, and at the same time dispense with the efforts of a cultured sense.

Those, therefore, who are concerned with the education of the surgeon of the future would do well to still cherish this ancient power, and to foster a memory of the fact that surgery is, in its very essence, a handicraft, and that in all that he does the surgeon's great endeavor should be to make his own hands self-sufficing.

It is sad to think that this hardly-acquired faculty dies with the possessor of it, and never was this more vividly presented than it has been by the loss which surgery has sustained in the death of Sir James Paget. One can picture the great surgeon composed in his last sleep, and can see the once busy fingers lying lifeless on the white sheet, and then comes the wonder at the wealth of learning, at the exquisite cunning, at the refined sense which lay dead in the dead hand. No written book can hold a tithe of the dainty knowledge which had been mastered by those subtle fingers, and no record, however labored or however loving, can tell of the power which once rested in that magic touch.

An individual loss does not, however, hinder the general tide of progress. Advance in such a work as ours depends upon the uneventful work of the whole body and is only accentuated by the achievements of the prominent few. The movement is the movement of a multitude in which individuality is, at a distance of time, little to be distinguished and in which personal eminence contributes a smaller factor than the present is ready to acknowledge. Those who stand forth as the leaders of the advance are merely the elect of the common body and the representatives of a wide intellectual franchise. Even he who startles the world as a discoverer has often done little more than give expression to what was already nascent in the multitude. So as one great surgeon after another drops out of the ranks his place is rapidly and imperceptibly filled, and the advancing line moves on with still the same solid and unbroken front.

The continuity of progress is undisturbed by the uncertainties of human life, and, as one writer has well expressed it:

"No work begun shall ever pause for death."

The Plague.—George Adami (*Montreal Medical Journal*, April, 1900) contributes an interesting article upon the plague, entitling it "A Prospect and a Retrospect." He reviews the history of the disease through modern times, laying particular stress upon the remarkable diversity of symptoms. The one feature of bubonic enlargements has existed, however, in all epidemics. He enjoins particular investigation and care in all cases of nonvenereal bubo, especially if accompanied by slight fever and white-coated tongue, red at the tip and edges. It is a curious fact that the known danger of handling rats dead of the disease extends at most 24 hours; thus it is indicated that the infection is by means of parasites on the rat's body, deserting these bodies after death. The primary seat of infection is, in the majority of cases, unrecognizable; the glands of the groin and of the axilla are by far the commonest seats of primary bubo. [M.B.T.]

Transscapular Amputations.—N. Senn (*Denver Medical Times*, May, 1900) believes that a distinct line should be drawn in performing serious operations between cases in which it is absolutely necessary to remove the entire scapula and a part of the clavicle and those in which a radical operation may be performed by resorting to transscapular amputation. He details 2 cases, one of periosteal sarcoma involving the upper portion of the humerus, for which exarticulation was performed 12 years before. In this case he made a V-shaped flap, sawed the neck of the scapula through, reflecting the tissue outside the incision to the axillary space; the axillary artery was then secured, the nerve severed and tumor removed. Thorough drainage was established at the most dependent portion of the amputation wound, which healed very kindly by primary intention. The second case was one of periosteal sarcoma originating at the site of a fracture of the upper portion of the humerus, forming in place of the normal bony callus. This was operated upon in the same way as the first case, but slightly modified. The first incision was anterior through the pectoral muscle and the vessels were ligated through this incision; the second incision, posteriorly, circumscribed the tumor, and the scapula was divided through the neck through this incision. The patient suffered very little shock and the wound healed by primary intention. [M.B.T.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Anthrax has again made its appearance at Falls Creek, a suburb of Dubois, Pa. The origin of the disease has been traced to a tannery.

State Board Examination.—The results of the June examination were made known July 30. Of the 360 applicants for licenses to practise medicine only 44 were rejected.

W. W. Keen, F. R. C. S.—The Royal College of Surgeons, England, at the recent centennial exercises, made Professor W. W. Keen, of Jefferson Medical College, Philadelphia, a Fellow. The honor could scarcely have been bestowed more worthily.

Lived Three Weeks with Broken Neck.—Lewis T. Vogel, who had been in the Samaritan Hospital for 3 weeks with a broken neck, died July 25. He was conscious until within an hour of his death. He fell from a tree and fractured the fourth cervical vertebra. He retained consciousness, but sensation below the fracture was lost. He gained slight control over his left arm, and was capable of feeling in the upper part of his chest.

Western Pennsylvania Medical College.—The following changes have been made in the teaching force of the Western Pennsylvania Medical College, to take effect at the coming session. Dr. T. M. T. McKennan changed from the chair of anatomy to that of nervous and mental diseases; Dr. T. L. Hazzard from physiology to that of diseases of the rectum; Dr. E. S. Montgomery has been made professor of practical anatomy, Dr. James Witherspoon professor of descriptive anatomy, Dr. S. C. Milligan professor of physiology, Julius A. Koch professor of pharmacy in the Pittsburg College of Pharmacy, professor of chemistry, and A. F. Judd demonstrator of pharmacy.

Vital Statistics of Philadelphia for the week ended July 28, 1900:

Disease.	Cases.	Deaths.
Total mortality	511	
Inflammation of appendix 6, bladder 2, brain 15, bronchi 3, kidneys 15, heart 1, liver 1, lungs 24, pericardium 1, peritonæum 10, pleura 2, stomach and bowels 27, uterus 1		169
Cholera infantum		75
Inanition 13, marasmus 31, debility 3		47
Lungs—tuberculosis of 42, abscess of 2, congestion of 1		45
Heart—disease of 26, neuralgia of 2		28
Sunstroke		26
Sarcoma of hip 1, carcinoma of pylorus 1, bowels 1, breast 1, colon 1, liver 4, stomach 9, uterus 1		19
Convulsions 17, puerperal 1		18
Apoplexy 13, paralysis 4		17
Old age		17
Bright's disease 9, uremia 3, diabetes 1		13
Brain—disease of 1, dropsy of 2, tumor of 1, congestion of 2, softening of 4, concussion of 2		12
Typhoid fever	49	12
Measles		9
Diphtheria	46	8
Cirrhosis of liver		5
Casualties		5
Drowned		4
Suicide—carbolic acid 2, drowned 2		1
Erysipelas		1
Diarrhea		3
Dropsy		2
Scarlet fever	17	1
Abscess of jaw 1, alcoholism 2, asthma 2, burns and scalds 2, cerebrospinal meningitis 1, carbuncle 1, childbirth 1, membranous croup 1, abdominal dropsy 1, epilepsy 1, gangrene of foot 2, whooping-cough 1, traumatism 1, tetanus 1, tubercular mesenterica 1, syphilis 1, septicæmia 2, surgical shock 2, carbolic acid poisoning 1, obstruction of bowels 2, locomotor ataxia 1, indigestion 1, hernia 2, hemorrhage of uterus 1		32

New Dental College for Philadelphia.—By the settlement of the will of the late Dr. Thomas W. Evans, who was Paris' American millionaire dentist, \$3 000,000 will go to found a dental institute in Philadelphia. Work will begin shortly on the new college.

Centenarian Recovers from Operation.—Harold Beyer, of Philadelphia, in his one-hundredth year, was recently operated upon for strangulated hernia at the Presbyterian Hospital by Dr. DeForrest Willard. Despite his great age his recovery was rapid.

Sources of Pollution of Schuylkill.—The sources of pollution of the waters of the Schuylkill have occupied the attention of members of the State Board of Health for some time past. In June these officials made a trip along the Upper Schuylkill and inspected the large industrial establishments in and near Reading, the surface drainage of which runs into the river, and they have succeeded in having a number of nuisances of this character abated. Recently the same officials visited Norristown, where they made an inspection of the sewerage system of that place, and, if necessary, suits will be instituted to compel the abatement of many nuisances of this character which are known to exist there.

Decisions Rendered in Oleo Cases.—The Superior Court recently rendered 2 important decisions in oleomargarine cases. In the first, that of M. M. Diefenbocker, who was convicted in the Quarter Sessions Court of Erie County of selling oleomargarine contrary to law, the court decided that a civil suit to recover the penalty for the violation of the oleo law does not bar a criminal prosecution. In the case of Owen McCann against the Commonwealth an appeal from Common Pleas Court No. 3, of Allegheny County, in which the constitutionality of the act of May 5, 1899, was attacked, the court sustained the act by affirming the decision of the lower court, in which McCann was convicted and judgment entered against him by an alderman in a suit for a penalty for selling oleomargarine in imitation of yellow butter.

NEW YORK.

The New York School of Clinical Medicine has not been discontinued, as reported some time ago, although some members of the teaching staff have retired.

The American Society for the Prevention of Premature Burial, with principal offices in New York City, has filed articles of incorporation with the Secretary of State.

Troy City Hospital.—It is announced that arrangements are being made for the celebration of the fiftieth anniversary of the founding of the Troy City Hospital, August 15.

Physician Nominated for Governor.—At the Prohibition State Convention held at Utica, N. Y., Dr. William T. Wardwell was nominated for Governor. He is president of the Red Cross Hospital in New York.

Dr. Pilcher Honored.—The Board of Regents of the University of Michigan conferred the honorary degree of LL.D. at the commencement exercises held June 21 upon Lewis S. F. Pilcher, Brooklyn, N. Y., professor of surgery in Long Island College Hospital and editor of the *Annals of Surgery*.

Forests for Consumptives.—The State Forestry Commission, of New York, will purchase 40,000 acres of land at the head waters of each of the 3 principal rivers of the State, in order to rear forests. This is looking forward to the future State care of tuberculous individuals and also for out-door recreation for other invalids.

State Hospital for Tuberculous Patients.—The trustees of the New York State Hospital for the treatment of tuberculosis met at Raquette Lake July 26 and elected the following officers: President—Howard Townsend, of New York; secretary—John R. Pryor, M.D., of Buffalo; treasurer—Frank E. Kendall, of Saranac Lake. It is understood that a site will be shortly selected, and that the erection of the hospital will begin soon.

Typhoid Epidemic in Watertown.—In Watertown, N. Y., 50 cases of typhoid are said to be in charge of the physicians. At least 6 deaths have resulted in the last fortnight. The cause is ascribed by physicians to impure wells and the decayed fruits and vegetables sold in the market. Many wells have been closed up by the authorities.

The City and the Homeopathic Hospital Debt.—The Board of Estimate and Apportionment of New York at a meeting, July 26, completed arrangements for the transfer of the Brooklyn Homeopathic Hospital property to the city. When the details came up for settlement there were \$70,000 debts on the hospital, which the city was called upon to assume.

Jersey City Pupils' Poor Eyes.—At the request of the Jersey City School Board, the eyes of 351 school-children were examined by Dr. Walter Pyle. Of these only 69 had perfect eyesight and 71 not only had imperfect vision but were in danger of becoming permanently affected. There were many children who would be benefited by wearing glasses, but who do not wear them.

Physicians Refuse Certificate.—Andrew Jaffrey died in New York, July 24, from diphtheria. Dr. John E. Harrity, who last attended the boy, refused a death-certificate because he had not been in attendance for 24 hours before the death, and Dr. Annie S. Daniels, of the New York Infirmary Dispensary, refused a certificate because she had not attended the boy at the time of death. The Board of Health was notified by Dr. Harrity. The body was sent to the Morgue and an investigation will be made.

Albany Medical College.—Some changes have been made in the faculty for the session of 1900-01. Dr. A. Macfarlane, formerly clinical professor of physical diagnosis and lecturer on medical jurisprudence, has been promoted to the adjunct professorship in this department. Dr. A. G. Root, formerly lecturer on diseases of the throat and nose, has been made clinical professor. Dr. J. M. Mosher has been made lecturer on insanity, neurology, and electrotherapeutics. Dr. H. Judson Lipps was promoted to lecturer on obstetrics.

Decrease in Blindness.—A great reduction in the number of inmates of the Institution for the Blind in New York is attributed to the better care of the eyes of children in the homes of the poor and in the charitable institutions of the metropolitan district. This explanation is given by the Committee on the Blind of the State Board of Charities, who found only 127 pupils in this Institution—about half the number reported a year ago. The State School at Batavia, on the other hand, is overcrowded, and must reject many applications for admission.

NEW ENGLAND.

Smallpox at Lowell.—An epidemic of smallpox, which began last May, has been revived in Lowell, Mass. There were 13 patients at the contagious disease hospital on July 27, and one death is reported.

Faith Curist's Mail Stopped.—The Post Office Department has issued a fraud order against Francis Truth and the Francis Truth Institute of Divine Healing, Boston, Mass. Truth was recently convicted of fraudulent use of the mails. The Post Office in Boston has held up a large amount of mail, and it will be returned to the senders under the rules obtaining in such cases.

Boston Board of Health and Sanitary Product Company.—The Boston Board of Health, July 27, brought a bill in equity in the Supreme Court against the New England Sanitary Product Company to restrain the defendant from occupying or using the garbage plant at Cow Pasture, Dorchester district, and from carrying on the trade of treating garbage there; and also to have ordered to remove any garbage that may be in or about the scows and buildings. The grounds of the bill are that the defendant has never asked for, nor has it been granted, an assignment by the Board of Health of a location to carry on its trade or business of rendering garbage; that its plant and buildings, by reason of offensive and hurtful smells and exhalations issuing from them when in operation, are a nuisance, and that the business

itself, as conducted by the defendant, is an offensive trade and occupation, and is being illegally carried on without the written consent of the Mayor and aldermen having first been obtained.

CHICAGO AND WESTERN STATES.

The Protestant Episcopal Hospital of Cincinnati received \$3,000 by the will of the late T. H. C. Allen.

Scarlet fever again prevails at Plainfield, Wis. In the spring the epidemic was severe and all danger was supposed to have passed.

Smallpox in California.—An epidemic of smallpox has visited Rio Vista, on the Sacramento River. There are 8 cases reported. Later reports state that the epidemic is past the danger line. No new cases have occurred recently, and a pest house has been established away from the town.

Saloon Keepers and W. C. T. U.—The Chicago saloon keepers have joined hands with the Woman's Christian Temperance Union in an effort to suppress the importation into this country of absinthe. This queer anomaly is explained by the saloon men to be due to the fact that there is no profit in selling this drink.

Smallpox Among the Cherokees.—A coach occupied by a company of Italians was left on the siding near Adair, I. T., July 23, as soon as a case of smallpox was discovered on board. Guards have been placed around the car and it will be converted into a pest-house to prevent spread among the Cherokee Indians living near.

Milk Dumped Into Sewers.—Health-Officer Chalmers, of San Francisco, had 6 inspectors out early July 22 to hold up the milkmen, and the result was that 309 gallons of impure milk was dumped into the sewers. Dr. Chalmers asserts that over 1,000 gallons would have gone the same way if he had been permitted to employ enough men to cover the territory. In nearly every instance the milk was found to be far below the standard.

Confession of Dowie.—The Zion boss has made a frank confession in his "Leaves of Healing" recently of his money-making intentions in his alleged faith healing schemes, but says the plans are of divine origin, and that the cause cannot be carried on without money. He holds nearly \$2,000,000 in his own name, contributed by his deluded followers. Dowie is contemplating moving his purposed Zion city a few miles farther north of Benton, Ill., to Winthrop Harbor.

Treated by Christian Science.—Mrs. Thomas E. Scantlin, of Lafayette, Ind., who has been treated by her husband according to Christian Science methods since the 8th of last June, had an operation performed in the St. Elizabeth Hospital, July 27, for strangulated hernia. Most of the five physicians present thought her case had gone so far that nothing could be done to save her life, but the operation was performed and the patient rallied so that there are slight hopes for her recovery.

New Hospital in St. Louis.—A resolution was recently offered at a meeting of the City Council of St. Louis, requesting the Board of Public Improvements to prepare and submit to the Council the draft of an ordinance authorizing immediate action to provide a city hospital for the indigent sick and insane. The text of the resolution implies that the present hospital fund of \$258,340.76 be utilized as a beginning, and the annual income of about \$50,000, or 1% of the entire municipal revenue set apart to the hospital fund, be utilized from year to year. The resolution was adopted.

Chicago Pure Food Law Offenders.—The law which went into effect July 1, specifies that butterine and oleomargarine must be labeled clearly. The butter men have complained that while the law has been in effect nearly a month and that just as much oleomargarine is now sold for pure butter as before, there have been no prosecutions by the pure food commissioner. Commissioner Jones reports that inspectors have been at work since the law became effective, and have found a number of places where oleomargarine was being sold as butter. The chemical analyses of the samples will be completed and warrants issued soon.

Chicago's Death Rate.—The latest bulletin of Chicago's health department shows that the death-rate from 1880 to 1897 greatly decreased. From 1880 to 1884 it was 21.9 to 1,000 population, from 1885 to 1889 it was 19.2. From 1890 to 1894 the rate was 17.9 and from 1895 to 1899 it was 14.9. "This shows," as the bulletin remarks, "a reduction in the last period from the death-rate of the first period of more than 35%—an improvement unequalled in any other large city of the world." The year of lowest mortality was 1897 when the rate was 13.46, since then the rate has increased. This increase is said to be due to the recent sanitary neglect of the city, although this may be in some measure offset by the neglect of sewers, street cleaning, and garbage collection.

Lane Medical Lectures.—The fifth course of the Lane Medical Lectures, inaugurated in Cooper Medical College in 1896, will be given in 1900 by Sir Michael Foster, professor of physiology, University of Cambridge, England.

These lectures will be given on the days and hours as follows:

August 20, 11 A.M., Vesalius, his Forerunners and Followers; the Beginning of Modern Physiology.

August 20, 8 P.M., Harvey and the Circulation of the Blood, The Lacteals and Lymphatics.

August 21, 11 A.M., Borelli and the Influence of the New Physics.

August 21, 8 P.M., Malpighi and the Physiology of Glands and Tissues.

August 22, 11 A.M., van Helmont and the Rise of Chemical Physiology.

August 22, 8 P.M., The Physiology of Sylvius and his Pupils, Digestion in the Seventeenth Century.

August 23, 11 A.M., The English School. The Physiology of Respiration in the Seventeenth Century.

August 24, 8 P.M., Haller and the Physiology of the Nervous System.

SOUTHERN STATES.

Smallpox in Jackson.—A death from smallpox occurred at Jackson, Miss., July 18, and 5 cases have recently developed; these were contracted before quarantine was adopted.

Health Officer for District of Columbia.—At a meeting of the Board of District Commissioners, July 26, Dr. William C. Woodward was reappointed health officer for the district for a term of 3 years from August 1, 1900.

Cattle Disease Attacks Stockmen.—Charbon has spread to an alarming extent among the cattle of Edwards County, Tex. Thousands of the animals have died and the disease has attacked the families of stockmen, causing a number of deaths. A rigid quarantine is being enforced against the infected county, and all possible precautions are being taken to prevent a further spread of the disease.

The American Association of Obstetricians and Gynecologists will hold its thirteenth annual meeting at the Galt House, Louisville, Ky., September 18, 19, and 20, 1900. The following papers among others have been offered: Diagnosis of ectopic pregnancy before rupture, based on 10 cases, J. F. Baldwin, Columbus; The private hospital, Joseph Price, Philadelphia; Extirpation of the rectum and sigmoid per vaginam, John B. Murphy, Chicago; A satisfactory method for suspension of the uterus, Robert T. Morris, New York.

Baltimore Hospitals Refuse County Patients.—The Baltimore County Commissioners communicated with the Maryland University Hospital in Baltimore regarding its refusal to take accident patients from Baltimore county. County Chief of Police appeared before the Commissioners and reported that he experienced great difficulty in arranging for the care and treatment of persons injured by accidents upon the railroads and otherwise in the county. Some of the hospital authorities of Baltimore object to receiving persons who sustain injuries outside of the city limits, and recently it was reported that the Maryland University Hos-

pital positively would receive no more such cases from the county.

Quarantine Conflict.—The first quarantine conflict of the season is reported between Louisiana and Alabama. Both States have quarantine inspectors at the several Central and South American ports, who report whenever cases of yellow fever occur there. The Louisiana inspector reported one case of yellow fever and several suspicious cases at Puerto Cortez, Costa Rica, and the Louisiana Board of Health proclaimed quarantine against that country. The quarantine inspector of the Alabama Board of Health did not agree with Dr. Wood in the diagnosis of the disease in Puerto Cortez, and refused to report it as yellow fever. Alabama, therefore, refused to quarantine against Costa Rica. The action of the Louisiana Board of Health has had the effect of turning the fruit trade temporarily from New Orleans to Mobile.

MISCELLANY.

A Peculiar Disease in Alaska.—It is reported that a disease resembling la grippe, and said to be very fatal, prevails on the seal islands in Behring Sea.

Yellow Fever Among Soldiers in Cuba.—At Pinar del Rio 11 deaths are reported while 8 cases and 11 suspects are under observation. The disease obtained headway before positive diagnosis. Cases are also reported among the troops at Matanzas.

More Medical Officers Needed.—General Sternberg says that 100 additional medical officers are wanted for duty in the Philippines and China. He says that only graduates of reputable medical colleges, with some experience, and under 40 years of age, will be accepted.

Food for Starving India.—The State Department has received word from the United States consul at Bombay, India, reporting the arrival at that port on June 25 of the steamship *Quito*, with 5,000 tons of corn, contributed by the people of America for the relief of the famine sufferers in India.

Hobson to Consult an Oculist.—The *Coptic*, which has just arrived at San Francisco, had Lieut. Hobson as a passenger from Hong Kong for San Francisco, but he was obliged to leave the vessel at Yokohama for medical treatment. He is afflicted with retinitis and will go from Yokohama to Tokio to consult a Japanese specialist.

For Ninth Regiment Wounded.—The Hospital Ship *Maine* Committee has received a donation of \$5,000 from Mrs. Alfred Corning Clark, of New York, with a request that it be devoted to the aid of the Ninth United States Infantry wounded. Another subscription of \$1,000 from an anonymous source brings the total since July 12 to about \$7,000.

The "Arethusa" to Carry Surgical Supplies to China.—Surgeon-General Van Reypen, of the Navy, has arranged to send direct to our ships at Taku a quantity of surgical supplies and dressings on the *Arethusa*, which sails shortly by way of Suez. To meet any possible necessities 6 additional assistant surgeons were sent out to the Asiatic station some time ago. From the standpoint of the Navy the situation, so far as the medical corps is concerned, is considered to be well in hand.

Medical Supplies for Troops.—Surgeon-General Sternberg has made every arrangement for the care of the sick and wounded soldiers on Chinese soil. Provision has been made by the Quartermaster's Department for the immediate transportation of an abundance of medical stores and supplies. The nature of the situation precludes the establishment of a general hospital. It has been decided to confine present efforts to the establishment of a suitable field hospital in the immediate vicinity of military operations.

Hebrew Charities.—The report of the United Hebrew Charities for the month of June shows that the total number of applications received and dealt with during the month reached 3,417, representing about 11,390 individuals. Regular monthly allowances were given in 385 cases not included in the number of applications here given. Transportation to

different parts of the country and Europe was supplied to 85 persons. To homeless men and women 40 nights lodgings and 141 meals were furnished. The nurses of the institution made 900 visits to 57 cases, and 57 persons were supplied with nourishing food.

Expert in Mental Diseases to be Sent to the Philippines.—Surgeon-General Sternberg has decided to station an expert in mental disease at Manila, to have charge of insane patients prior to their embarkation for this country. For this purpose he has given a contract as acting assistant surgeon to Dr. Charles H. Latimer, who has been a member of the staff of the Government insane asylum at Washington for the past 12 years. He takes with him as assistants 2 attendants from the Government asylum for the insane, who have each had more than 10 years' experience in handling such cases.

Obituary.—J. LEONARD, of Chicago, July 21, aged 46.—GEORGE W. LEWIS, of Buffalo, July 24.—THOMAS J. BOYLE, of Houston, Texas, July 22, aged 50.—JOHN D. CARPENTER, of Rolla, Mo., July 23, aged 50.—D. L. SHEA, of New York, July 24, aged 35.—HENRY T. HEROLD, of Newark, July 25, aged 38.—EMMANUEL A. GRIVEAUD, of St. Louis, July 26.—SAMUEL A. H. McKIN, of Washington, D. C., July 26, aged 74.—RICHMOND J. SOUTHWORTH, of Georgetown Heights, July 27, aged 59. J. B. WELCH, in Wilmington, Del., July 27, aged 72.—WILLIAM J. WOODRUFF, of Providence, R. I., July 28.—T. LOUIS BROWN, of Cincinnati, July 23, aged 65.—GEORGE L. LIDDELL, of Toronto, July 5, aged 32.

Separation of Xiphopagus Twins.—On May 30 of this year, Dr. Chapot Prevost, of Brazil, separated the twins which have been the subject of much medical discussion during the past year. They were not united by a single band as were the Siamese twins, but their abdominal cavities were connected by a large opening, practically forming one cavity, and the thoracic cavities were also implicated, while the livers were united in nearly their whole extent. They had been under observation at the hospital at Rio de Janeiro since last October. One had an attack of grip with corresponding temperature and pulse, while the other remained well. This led to the belief that no psychological conditions forbid their separation. On the seventh day after the operation one of the twins died, the other continues to improve without any drawback. An autopsy revealed a state of inflammation of the pleura and pericardium with exudation, while the liver was completely healed.

Smallpox at Nome.—Captain Tuttle, of the revenue cutter *Bear*, in a report says: "The situation along the whole coast I regard as very serious. It is estimated that at present there are within a radius (taking the United States Post Office as a center) of 10 miles 25,000 people. Most of them are living in tents either on the beach or tundra. The sanitary condition of the portion of the city where houses have been erected is simply frightful. Typhoid fever is raging and smallpox steadily gaining. All possible efforts are being made to stamp out the smallpox, but with so many thousands of tents, scattered over miles of territory, it is impossible for the health authorities to keep track of all cases. As nearly as can be traced, the disease was introduced from the steamer *Oregon*. Afterward the steamers *Ohio* and *Santa Anna* were found to be infected, and were placed in quarantine. The *Oregon* had left before her cases were discovered."

Possible Peril for Army Nurses.—China is not a party to the Geneva Red Cross Convention, by which the signatory powers bound themselves in time of war to respect the Red Cross and to treat surgeons and nurses belonging to the armies of the enemy as noncombatants. China is, in fact, the only one of the great powers of the world which has not joined in this convention which assures the safety of those on errands of mercy on the battlefield. It is reported that this fact may deter the War Department from permitting any of the women nurses who are being sent to the Far East from landing in China for duty there. There are 19 female nurses on the transport *Grant* with General Chaffee. They were destined for the Philippines, but might be landed in China if conditions were such that they could be useful and not put into unnecessary peril. There are also 5 nurses on the *Sumner*. There are now 145 army nurses, practically all

of whom are either in the Philippines stationed at the hospitals of the various garrisons throughout the archipelago, or on their way there.

Honorary Fellowships.—The centenary meeting of the Royal College of Surgeons this afternoon was the occasion for the presentation of diplomas of honorary fellowship to a large number of distinguished personages from all parts of the world, including Lord Salisbury, Lord Rosebery, Dr. W. S. Halsted, of Baltimore; Dr. W. W. Keen, of Philadelphia; Dr. R. E. Weir, of New York; Dr. J. C. Warren, of Harvard; Dr. I. H. Cameron, of Toronto; Sir W. H. Hings-ton, and T. G. Roddick, of Montreal; Edward Albert, of Vienna; Charles Bent Ball, of Dublin; Eduardo Bassini, of Padua; Edward Hallaran Bennett, of Dublin; John Wilhelm Berg, of Stockholm; Oscar Thorwald Block, of Copenhagen; Enrico Bottini, of Pavia; Dr. Salvador Fernandez Cardenal of Barcelona; Antonito D'Antora, of Naples; S. Exc. Prof. Dr. Ernst von Bergmann, of Berlin; Francesco Dorante, of Rome; S. Exc. Prof. Dr. Friedrich von Esmarch, of Kiel; Surgeon-General James Jamieson, of the Army Medical Service; Theodor Kocher, of Bern; Franz König, of Berlin; Ernst Georg Ferdinand Küster, of Marburg; Elie Lambotte, of Brussels; Odilon Marc Lannelongue, of Paris; Karl Gustaf Lennander, of Upsala; William MacEwen, of Glasgow; Col. Kenneth MacLeod, of Netley; Julius Nicolaysen, of Christiania; Sir Henry Frederick, of the Royal Navy; Léopold Ollier, of Lyons; Victor Pachoutine, of St. Petersburg; Samuel Pizzi, of Paris; Col. Daniel Charles O'Connell Raye, of the Indian Medical Service; Frederico Rubioy Gali, of Madrid; Nicolas Wassilievitch Sklifossovsky, of St. Petersburg; Paul Tillaux, of Paris; Nicolas Weliaminoff, of St. Petersburg.

Text of German Meat Laws.—A copy of the German meat inspection law, which has been vigorously denounced by the antiagrarian members of the German Reichstag and has been the subject of diplomatic interchanges of opinion between the American and German Governments, has been received. Proprietors of packing houses in the United States believe that the bill will end a great portion of our growing export of meat to Germany. One of the provisions practically puts an end to the importation of sausage or other chopped meat into Germany, and another, due evidently in part to the agitation about the use of preservatives on meat sent to the army in Cuba in 1898, prohibits the importation into the Zollverein of meat on which preservatives harmful to human health have been used. The fact that any preservatives used are harmless must be instantly ascertainable. Fresh meats must be imported in whole carcasses or in halves and with most of the organs attached to the carcass, that the healthfulness of the meat may be better judged. Meat that has had preservatives applied to it, but from which their traces can readily be dissipated, may be imported under the terms accorded fresh meat. All of these regulations are to be in effect until January 1, 1904. Horse meat may be imported as such and may be sold in licensed establishments which advertise the fact that horse flesh is for sale. Cattle on the hoof may be imported into Germany and slaughtered there under local regulations that provide strictly against the unhealthy meats getting into the market. Severe penalties are provided for infraction of the law and the use of any unhealthful ingredient in the packing of meat is strictly prohibited.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended July 26, 1900:

Changes in the Medical Corps of the U. S. Army
for the week ended July 28, 1900:

PLUMMER, GEORGE R., acting assistant surgeon, is relieved from the duty at Columbia Barracks, Cuba, and will join his former station, Battery No. 3, artillery defences of Havana, Cuba.

COOKE, ROBERT P., acting assistant surgeon, is assigned to duty at Pinar del Rio Barracks, Cuba.

DUCKER, MAJOR ORLANDO, surgeon, is relieved, and Major Rafael Echeverria, surgeon, is announced as military sanitary officer of the municipality of Marianao in his stead.

KEAN, MAJOR J. R., surgeon, is granted leave for 1 month, with permission to go beyond the limits of the division of Cuba.

HAYWARD, EDWARD P., acting assistant surgeon, is assigned to duty at the U. S. General Hospital, Presidio.

RICHARDSON, GEORGE H., acting assistant surgeon, is relieved from duty at the U. S. General Hospital, Presidio, and assigned to temporary duty on the U. S. transport "Sumner," to relieve Acting Assistant Surgeon George E. Maurer.

MAURER, GEORGE E., acting assistant surgeon, will proceed to New York City and report by letter to the Surgeon-General of the Army for annulment of contract at his own request, his contract having expired.

USHER, First Lieutenant F. M. C., assistant surgeon, is relieved from further duty with the garrison of Matanzas, Cuba, and will report to the commanding officer of the first battalion of the Tenth Infantry, for duty with the battalion while en route to Santiago de Cuba. Upon arrival at Santiago de Cuba Lieutenant Usher will report to the commanding officer of the Fifth Infantry, for duty with that regiment while en route to New York, and on arrival at the latter place will report by telegraph to the Adjutant-General of the Army for further instructions.

SHELBY, W. D., acting assistant surgeon, is relieved from further duty with the garrison of Matanzas, Cuba, and will report to the commanding officer, Tenth Infantry, for duty with the command while en route to Cienfuegos, Cuba, and upon arrival at the latter place will report to the commanding officer, Second Infantry, for duty with, and to accompany the regiment to the United States.

LAWRENCE, W. P., acting assistant surgeon, is relieved from further duty at Saneti Spiritus, Cuba, and will proceed to Cienfuegos, Cuba, reporting to the commanding officer, Second Infantry,

for duty with, and to accompany that regiment to the United States.

HUGHES, L. S., acting assistant surgeon, is relieved from further duty at Caibarien, Cuba, and will proceed to Cienfuegos, Cuba, reporting to the commanding officer, Second Infantry, for duty with, and to accompany that regiment to the United States.

CORRISIER, HAROLD D., acting assistant surgeon, will report for duty to the commanding officer, Fifteenth Infantry.

AMADOR, RAOU L. A., acting assistant surgeon, will report to the chief sanitary officer of the city of Havana, for duty at the Las Animas Hospital.

POLHEMUS, CAPTAIN ADRIAN S., assistant surgeon, will proceed from Fort Leavenworth to Fort Robinson, for the purpose of accompanying troops A and C, First Cavalry, from the latter post to Seattle, Wash. After arrival of the troops at Seattle, Captain Polhemus will return to his proper station, Fort Leavenworth.

WILCOX, CAPTAIN CHARLES, assistant surgeon, will proceed to San Francisco, Cal., and report to the commanding general, department of California, for duty with the Ninth Cavalry, en route to Manila, P. I.

DE LOFFRE, SAMUEL M., acting assistant surgeon, will proceed from Washington, D. C., to Omaha, Neb., and report to the commanding general, department of the Missouri, for duty to accompany the First Cavalry from that department to the Philippine Islands, and upon arrival at Manila will report to the commanding general, division of the Philippines, for assignment to duty.

CHAPMAN, W. EARLE, acting assistant surgeon, will proceed from Sheboygan, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

MANY, HARRY C., acting assistant surgeon, will proceed from Honesdale, Pa., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

NEWTON, RALPH W., acting assistant surgeon, will proceed from Barre, Vt., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

RENO, WM. W., acting assistant surgeon, will proceed from Detroit, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

ROWE, MICHAEL J., acting assistant surgeon, will proceed from Bridgeport, Conn., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

SPAETH, LOUIS A., acting assistant surgeon, will proceed from Jersey City, N. J., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

STREET, LIONEL A. B., acting assistant surgeon, will proceed from Brookline, Mass., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

UNOER, ISIDOR M., acting assistant surgeon, will proceed from New York City, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

LAMKIN, EDWARD E., acting assistant surgeon, will proceed from St. Louis, Mo., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

LEMEN, HARRY R., acting assistant surgeon, will proceed from Upper Alton, Ill., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

WETHERILL, First Lieutenant HENRY E., assistant surgeon, will report to the commanding general, department of California, for assignment to duty with the First Cavalry en route to Manila, P. I.

BYRNE, MAJOR CHARLES B., surgeon, is relieved from further duty at Plattsburg Barracks, and will proceed to San Juan, Puerto Rico, and report to the commanding general, department of Puerto Rico, for assignment to duty as chief surgeon of that department.

HOFF, MAJOR JOHN VAN R., surgeon, is relieved from further duty as chief surgeon, department of Puerto Rico, and will proceed to Washington, D. C., and report to the Surgeon-General of the Army, for instructions.

IVES, MAJOR FRANK J., surgeon, is relieved from further duty as chief surgeon, department of Matanzas and Santa Clara, and will proceed to New York City and report by telegraph to the Surgeon-General of the Army, for instructions.

MUNSON, CAPTAIN EDWARD L., assistant surgeon, in addition to his present duties, is assigned to the command of the U. S. General Hospital, Washington Barracks, during the absence of Captain William C. Borden.

BECKMAN, PETER W., acting assistant surgeon, will proceed from Alton, Ill., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

LAMB, DRYDEN H., acting assistant surgeon, will proceed from Owosso, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

CHASE, ALPHA M., acting assistant surgeon, will proceed from Denver, Colo., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

GIBRONEY, STUART G., hospital steward, office of the chief surgeon, department of Western Cuba, will be sent from Matanzas, Cuba, via New Orleans, La., to San Francisco, Cal., for transportation to China.

Changes in the U. S. Marine-Hospital Service, for the week ended July 26, 1900:

MAGRUDER, G. M., surgeon, is granted leave of absence for 14 days.
WERTENBAKER, C. P., passed assistant surgeon, to rejoin station at Wilmington, N. C., and upon being relieved by Surgeon T. B. Perry, proceed to New Orleans, La., and assume command of the service, relieving Assistant Surgeon J. W. Schereschewsky.
SCHERESCHESKY, J. W., assistant surgeon, is relieved from temporary charge of the service at New Orleans, La., and upon arrival of Passed Assistant Surgeon C. P. Wertenbaker directed to report to him for duty.
BAILEY, C. W., acting assistant surgeon, is granted leave of absence for 3 days.
FISCHER, A. W., acting assistant surgeon, is granted leave of absence for 15 days during the month of July.
STEARNS, W. L., hospital steward, is granted leave of absence for 23 days from August 6.
HOLSENDORF, B. E., hospital steward, is granted leave of absence for 30 days.
HOLSENDORF, B. E., junior hospital steward, promoted and appointed junior hospital steward.

Changes in the Medical Corps of the U. S. Navy, for the week ended July 28, 1900:

RUSSELL, A. C. H., surgeon, detached from the "Newark," and ordered to the Naval Hospital, Yokohama, Japan, for treatment.
KENNEDY, R. M., passed assistant surgeon, detached from the "Yorktown," and ordered to the "Newark."
GRUNWELL, A. G., assistant surgeon, detached from the "Brooklyn," and ordered to the "Monocacy."
GATES, M. F., surgeon, commissioned surgeon from July 7, 1900.
ROTHGANGER, G., surgeon, commissioned surgeon from July 7, 1900.
SPEAR, R., passed assistant surgeon, commissioned passed assistant surgeon from June 22, 1900.
ELMER, M. K., assistant surgeon, commissioned assistant surgeon from July 18, 1900.

Foreign News and Notes.

GREAT BRITAIN.

London Hospital for Sick Children.—John H. Morgan, on resigning the position of senior surgeon, has been unanimously elected consulting surgeon.

The Order and Insignia of the Medjidieh of the Second Class has been received by Dr. M. Armand Ruffer, president of the Sanitary, Maritime, and Quarantine Board of Egypt, from the Sultan of Turkey.

The Prince of Wales is now a Fellow of the Royal College of Surgeons. The president of the college, Sir William MacCormac, headed a deputation that presented him with the diploma, at Marlborough House, July 24.

Edinburgh Obstetrical Society.—On the recommendation of the Council of the Edinburgh Obstetrical Society, Professor Säuger, of Prague, and Professor Fehling, of Halle, were, after a ballot of the Fellows, unanimously elected Honorary Fellows.

Hertford British Hospital.—An address will be presented to Alan Herbert, physician to the Hertford British Hospital, by the former and present officers of the hospital, numbering 20, at the forthcoming International Medical Congress. The date of presentation is not fixed.

The Heath Scholarship, value £200, which is awarded every 2 years by the University of Durham, has this year been awarded to Dr. Nathan Raw, of Liverpool, and Major J. R. Dodd, R.A.M.C. The subject of the essay was, "The Urinary Tract, its Injuries and Surgical Diseases, their Pathology and Treatment."

The South African Hospitals Inquiry.—On July 17, Mr. Balfour was able to announce the names of the two additional members of the committee. Lord Roberts's two men of sound common sense have been found in Sir David Richmond, ex-Lord Provost of Glasgow, and Mr. Harrison, General Manager of the London and Northwestern Railway. The names of Lord Justice Romer, Dr. Church, and Professor Cunningham were previously announced.

French Hospital Appointment.—Dr. George Ogilvie has been appointed full physician to the French Hospital in the room of Dr. Keser, who has resigned owing to ill-health. Dr. Ogilvie has done the work of Dr. Keser at the hospital for more than a year. It may be mentioned that a necessary condition for tenure of the post is a colloquial mastery of the French language.

Purification of Sewage of Leicester.—Hitherto the sewage of nearly the whole of the city of Leicester has been treated, after passing through a settling tank of about 126,000 cubic feet capacity, by broad irrigation on about 1,355 acres of stiff clay land. Owing to the increase of population and other causes this land has become greatly overtaxed, and it has become imperative either to purchase a much larger quantity of land for the sewage farm, or to adopt some method of purification of the sewage before applying it to the land.

London's Spectacle Mission.—In London there is an odd philanthropic enterprise called the Spectacle Mission. It was founded by Dr. E. J. Warner over 10 years ago, and provides spectacles for poor working people suffering from defective sight. Last year over a thousand spectacles were given away by the mission. A subscriber of five shillings receives 4 spectacle cards for distribution; a ten-shilling subscriber 10 cards, and so on. The eyes of each applicant are carefully tested, and the spectacles are new, of good glass, with steel frames. Many a poor working man and woman has been enabled by this mission to retain employment.

Water Carriage.—At a recent meeting of the Manchester City Council an alderman proposed the following motion: "That in considering the plans of new buildings the Improvement and Buildings Committee be instructed not to insist upon the provision of water-closet accommodation, unless special circumstances render it desirable." His idea was that water should be carefully used until the laying of the second pipe from Thirlmere is completed, which will take 3 years. It was stated, however, that the effect of the present water-closet system on the water-supply was not appreciable. The motion was rejected.

The Undermanning of the Army Medical Service.—The following is the distribution of the active list of the Army Medical Service and Royal Army Medical Corps, according to the monthly Army list for July, 1900. The total strength increased during the month from 882 to 889. The home strength has decreased by 10 or including the 7 lieutenants gazetted by 17, which represents the increase of the South African establishment from 411 to 428. The numbers at other foreign stations show a decrease of 4, namely from 369 to 365. There are 120 retired officers employed, of whom 5 are in South Africa.

Retired Army Medical Officers.—There are 93 medical officers liable to recall; of these 18 are holding permanent appointments for officers on retired pay. The services of 25 others who volunteered to return to the service have been accepted, and they have been employed at home and abroad; none have been recalled by compulsion. Four officers are employed in South Africa on hospital ships. The 18 who are holding permanent appointments are officers of high rank, and it is thought better to employ in South Africa young civilian doctors who have more recent experience of hospital work.

Antityphoid Inoculation.—The Under Secretary of State for War has been asked whether his attention had been called to a report from Dr. Conan Doyle on the Lugman Hospital, South African Field force, Bloemfontein, in which he stated that there had been no death from enteric fever up to June 5 from among the inoculated; whether the War Office had yet any official statistics on the results of inoculation; and whether any further efforts were being made to increase the number inoculated in the men now going out to South Africa and China. Mr. Wyndham replied that the statistics at present available were not sufficient to enable him to give a reply to the first and second paragraphs of the question. Inoculation is offered to all men embarking from home for a country such as South Africa or China where enteric fever is prevalent, but such inoculation is purely voluntary.

Women Surgeons.—An interesting speech was made, says the *London News*, at the annual meeting of the new Hospital for Women, London—of which all the physicians, surgeons, and students, are women—by the eminent surgeon Sir Henry Smith. He stated that he had lately been present at a number of most serious operations performed by women surgeons, and had come to the conclusion that the small hands and delicate touch of women are particularly suitable for surgical work. The same tactile skill that makes a good needlewoman, he intimated, is of the highest use in modern "conservative" surgery; and he added that the results gained in that hospital would compare favorably with those recorded anywhere else.

Society for Relief of Widows and Orphans of Medical Men.—At a meeting of the Society in London, July 11, 1 new member was elected, the deaths of 3 members reported, and 3 persons had ceased to be members since April. The death of a widow who had received £35 a year since 1886 was announced. An application for grants for herself and 7 children was read from a widow, and grants at the rate of £100 a year were made. The husband, who met with a fatal accident in Australia, had only been elected a member in 1891, and had paid 18 guineas in subscriptions. A sum of £1,197 was voted for distribution among 48 widows, 14 orphans, and 6 recipients from the Copeland Fund. The expenses of the quarter were £44.12s.

The New Medical Bill.—A new bill to amend the Medical Acts 1858 to 1886, was introduced into the House of Commons by Sir Richard Jebb recently and was read a first time. The general objects of the bill are as follows: To enable the General Medical Council to suspend a medical man, guilty of misconduct, from practice for a limited period only; whereas, at present, he must be suspended, if at all, permanently. To strengthen the powers possessed by authorities granting diplomas to withdraw such diplomas from persons who have been already removed from the Register of Medical Practitioners. If a medical man, charged with violating the Medical Acts or one of them, is brought before a metropolitan police magistrate, and is fined, the fine goes to the Receiver of Police. The bill proposes that in such a case the fine shall be paid to the general medical council, and applied to the cost of enforcing the medical acts.

Housing and Improvement Association.—According to the *Lancet*, a conference was held recently in Hulme, "to consider the housing question as affected by the past clearance of low-rented houses and the threatened closing by the Sanitary Committee of the Manchester Corporation of many more, because of their alleged unfitness for human habitation." It was attended by many representative people. Resolutions were passed appreciating the action of the City Council in declining to sanction the further closing of houses in Hulme till provision has been made for those displaced, and yet assuring the Sanitary Committee of its support if they will only build as they pull down. The landlord of some of the condemned property brought forward a very familiar argument that there had been no infectious disease in that property for 20 years, and said that "there was too much of this pulling houses down." Such statements are always made where the death-rate is highest. The conference was constituted a permanent Housing and Improvement Association, and may, it is hoped, do useful work.

The Water-supply of Belfast has been the subject of much discussion. Many believe that the contamination of the catchment area is the cause of the present outbreak of typhoid fever. The present catchment areas—Woodburn and Stoneford, which have cost £700,000—give 11,500,000 gallons daily all the year round, and just now 13,000,000 gallons are the daily consumption. The present wet summer saved matters this year, but another summer cannot be faced without an additional supply, and if the city of Belfast increases as it has done since 1894 in 7 years hence 17,000,000 gallons daily will be needed. It is hoped that between April and July from 2,000,000 to 3,000,000 gallons daily may be obtained from the rivers at Kilkel, and during the other 8 months 10,000,000 gallons daily. Whether the water will be quite clear of sediment or peat remains to be seen. The Public Health Committee who was appointed to consider the question of the health of the city and how it could be im-

proved, with special reference to typhoid fever, recommends that the sewers and drains be more efficiently cleansed, ventilated, and flushed; that old courts, alleys, and drains be flushed out; that sewer atmosphere generated in the main drains be prevented from rising to the main levels of the city; that the milk-supply of the city be more effectively controlled; that the sale of shellfish from Belfast Lough be prohibited within the city; that a sufficient number of officers be provided for drain-testing; that the domestic scavenging of Belfast be improved; and that pollution of streams in the city be prevented. These precautions, it is thought, will keep down the normal rate of typhoid fever.

CONTINENTAL EUROPE.

Hydrotherapy.—An official chair of hydrotherapy is about to be established at Berlin. A hydrotherapeutic department in the Charité Hospital will be opened in the autumn under the direction of Professor Brieger.

Foreign University Intelligence.—Friedrich Schultz has been promoted to an extraordinary professorship of physiological chemistry at Jena. Dr. Axenfeld, of Rostock has been offered the chair of ophthalmology at Marburg. Dr. Bose has been appointed to the chair of physiological anatomy at Montpellier. Gustav Braun von Fernwald, of Vienna, is about to retire.

Pollution of the Seine.—The river Seine is not only teeming with filth of all kinds, but fish are dying by millions because the Paris Municipal Council has broken faith with the public and once again turned the city sewage into the river. So fearful has the stench been recently that nearly all the summer residents have been obliged to leave their villas. This applies to every place from the capital to Mantes. The sewage farm at Achères is entirely too small and the surplus matter must be got rid of in some other way.

The Medical Profession in Italy.—The statistics of the medical profession in Italy present something of the same state of overcrowding as elsewhere in the world. In 1876-7 there were 2,035 students of medicine, in 1891-7 there were 6,922. But it is puzzling to note that while the number of practising physicians in 1878 was 18,044, their number was only 20,000 in 1899. About 900 men leave the universities yearly, but only about 500 physicians are reported as dying in the same limit. In Italy there are some 9,000 *medici-condotti* or town-physicians (or health-officers), of these about 5,000 have a yearly salary, which in only 500 cases exceeds 3,000 *lire* a year. Some of the others, however, receive small stipends from the richer families of their districts.

MISCELLANY.

Famine Expenditures.—The Indian Government has spent in the last two years £13,000,000 on account of the famine and is prepared to spend £3,000,000 more in famine relief.

Plague.—The total number of cases of plague at Sydney to May 12 is 216 of whom 73 have died; 1,242 contacts have been isolated, of whom 153 still remain in quarantine. Among contacts 7 cases have occurred.

Obituary.—JAMES STEVENSON FORRESTER, on board the *Dunra*, June 18, aged 48.—DR. MOUCOT, Member of the French Chamber of Deputies.—DR. T. BECO, President of the Belgian Medical Commission.—NICHOLAS SMITH GLAZEBROCK, of Liverpool, July 14, aged 87.—FRANCIS RAWORTH HEYCOCK, of Hounslow, July 9, aged 58.—W. WELLINGTON LAKE, at Bloemfontein, July 13, aged 46.

The Antimalarial Expedition.—Dr. L. Sambon and Dr. Low, the two medical men intrusted by the British Government with the task of testing the possibility of guarding against malarial infection in the Roman Campagna, have found a favorable place for their purpose. They are about two miles from Ostia on the edge of a swamp. Their hut stands close to a canal containing a luxuriant growth of algae and other aquatic plants. The few dwellings near are infested by mosquitos of the anopheles variety and are inhabited by peasants who constantly suffer from malaria.

This spot offers ideal conditions for experiment. King Humbert manifested much interest in their trial, and had assisted them in many ways.

Japanese Medical Graduates.—A Japanese paper laments the fact that medical students in Europe graduate at 22 or 23 years of age while in Japan the age is over 26. The paper points out that Japanese mature and age earlier than Europeans, and that as the period of usefulness in life in Japan is over at 50 the period of active practice is short. In Europe a man is usually at his best at 50 and even at 60 or 70.

A Bountiful Benefactor.—M. Crevat-Durant, of Fontainebleau, who recently died, has bequeathed \$30,000 to the Pasteur Institute of Paris, \$80,000 to the *Ceuvre des Enfants Tuberculeux* of Ormesson, \$80,000 to the Society for the Protection of Children, and \$30,000 to the town of Fontainebleau for the enlargement of its hospital accommodation, besides large sums for many other charitable purposes connected with Fontainebleau.

The Prevalence of Venereal Diseases in Prussia.—With the object of obtaining accurate information as to the prevalence of venereal diseases in Prussia the Cultus-Minister, with the cooperation of the Medical Councils, has sent a circular to all medical practitioners asking them to state the number of patients coming to them for treatment between April 1 and 30 for gonorrhea and its sequels, for soft sores, and for syphilis, primary, secondary, or tertiary.

Inspection of Parisian Schools.—According to the *Lancet* the Minister of Public Instruction has just appointed a commission for the consideration of questions of health and sanitation in schools (*lycées*). This commission will advise on all matters relating to the care of the pupils, especially in boarding-schools, as well as to the sanitary condition of the school premises. The commission will inspect the *lycées* of the Department of the Seine at least once a year, and will hold special inspections whenever circumstances require them. The members of the commission may also be sent to inspect other schools. After each inspection, at which the medical attendant of the school has to be present, the commissioners will submit their observations to the Minister in a written report and will specify the improvements which they consider necessary.

China's Bad Water.—One of the greatest dangers to be encountered in campaigning in China is lack of water. The country has been so thickly populated for so many centuries that it is one vast graveyard. Then, too, there is no system of sewerage or drainage, except into cesspools, which often stand almost alongside the wells that supply the various communities. The water, therefore, is always reeking with the germs of typhus, typhoid, and that fearful oriental dysentery that makes living skeletons out of the strongest men in a few weeks. The Chinese manage to escape these epidemics by boiling all their water and drinking it hot. Quarantine is unknown in China, and it is common to see men all broken out with smallpox lying along the streets. The Chinese regard smallpox much as we do chickenpox—as something that everybody must have; in fact, among them measles is much more feared. The method of fertilizing the fields and gardens is such that all green things are poisoned with the same germs that taint the waters. As a rule vegetables and fruits are safe to eat in China only after they have been thoroughly cooked.

Rapid Diagnosis of Rabies in the Dog.—According to the *Lancet*, at the meeting of the Academy of Medicine, held on April 10, Professor Cornil read for M. Babès, of Bucharest, a short paper showing the possibility of making a rapid diagnosis of rabies by an examination of the medulla oblongata and spinal cord of a dog which had inflicted a bite. The process was as follows: 1. A small piece of the brain of the dog was inserted into the brain of a rabbit. 2. A slice of the medulla oblongata of the same dog was hardened in alcohol containing formal. At the end of 24 hours sections were cut from it and stained with carbolized fuchsin, methylene-blue, or polychrome. The sections were then dried, mounted, and examined with a low power. If *nodules embryonnaires* were found in the grey substance, together with a perivascular or general *état embryonnaire* and chromatolysis

of the nerve elements, this amounted to evidence that the dog was rabid. In all cases in which these bulbar lesions were observed it was found that the animals inoculated with brain-substance from the dog developed symptoms of rabies, while, on the contrary, such symptoms never appeared in rabbits inoculated with brain-substance from dogs the medulla oblongata of which did not present any of the above-mentioned alterations.

Oxygen in the Treatment of Seasickness.—According to the *Lancet*, on April 17 M. Dutremblay read a paper before the Academy of Medicine upon the treatment of seasickness by inhalations of pure oxygen under pressure. The first trials of this method were carried out with success by Dr. Dubois, professor at the Faculty of Sciences of Lyons, who considered that the principal cause of seasickness lay in the incomplete respiratory exchange which occurs in the lungs. The amount of residual air is thus increased. M. Dutremblay, assisted by Dr. Perdrilat, a medical officer in the service of the Compagnie Générale Transatlantique, made a trial of the remedy upon a number of seasick passengers. In his view the disturbances in position of the viscera and the contraction of the diaphragm bring about the secondary manifestations of seasickness, such as migraine, vomiting, chilliness, and the like. Under such conditions the use of oxygen is quite justified. The result of a great many trials was that rapid relief was obtained, the nausea and sickness disappeared, the patient felt quite comfortable, and to this there succeeded an interval of quiet and refreshing sleep. The shallow and rapid respiration became more regular, the pulse improved, and the headache disappeared. The patient must take deep and regular inspirations; from 30 to 40 liters are enough to begin with, but this dose may be repeated if necessary. The gas should be inspired through the mouth, the nostrils being kept firmly closed.

Cystin in Water-supplies.—At a recent meeting of the French Academy of Sciences, according to the *Lancet*, M. Armand Gautier presented a memoir by M. Causse, of Lyons, pointing out the significance of the occurrence of cystin in drinking water as an indication of the presence of germs of typhoid fever, and describing a method of determining its presence by a reagent which produces with it an orange-yellow color proportionate in its intensity to the amount of cystin contained in the water. By means of this reaction M. Causse has succeeded in estimating cystin quantitatively and is following out the varying proportions in which it exists in water. All the samples of water collected in houses where undoubted cases of typhoid fever had occurred, at La Guillotière, at Les Brotteaux, or in the central part of Lyons, acquired an orange tint throughout the whole mass of liquid. The depth of color, which was in a direct ratio to the proportion of cystin, seemed also to have a relation to the severity of the disease. The coloration of the water from the well of a house in the Avenue des Ponts, where 3 fatal cases of typhoid fever had occurred, was the deepest which M. Causse had obtained; the proportion of cystin was the highest which he had met with, the average being 3 centigrams per liter during the warm weather. The proportion of cystin varied very distinctly with the season of the year. Frequently repeated experiments showed that the intensity of the coloration, and therefore the amount of cystin contained in the contaminated water, was greatest in September and October; from October onward it diminished gradually, falling to the lowest point in February and March; it then increased, returning to its maximum at the end of the hot weather. The same remarks were applicable to the water of the Rhone as distributed by the water company. Compared with the wells at La Guillotière and Les Brotteaux, the amount of cystin in the water of the Rhone was estimated at about one-tenth part, but when the river overflowed its banks the proportion of cystin increased and in time of flood it became equal to, or sometimes even greater than, that contained in the worst well at La Guillotière; these fluctuations correspond with the fluctuations exhibited by typhoid fever, as is shown by statistics. Cystin in water was not only variable in amount, but it might almost completely disappear from certain waters, leaving only ammonia, sulphureted hydrogen and organic compounds to show that it had been there.

1.—Osler said if the license to practise meant the completion of his education how sad it would be for the doctor, how distressing to his patient! More clearly than any other, the physician should illustrate the truth of Plato's saying, that education is a life-long process. In the United States many special schools have been organized, and, perhaps, more systematic attention has been paid to **post-graduate study** than anywhere else, except in Germany. He had just finished a 6 weeks' course of clinical instruction to a class of about 30 general practitioners, and to meet these good, earnest students from all parts of the country, some of whom have been in practice 15 or 20 years, stimulates one's optimism as to the outlook in the profession. Mr. Jonathan Hutchinson bears a strong likeness to the immortal Hunter. No individual contributor in this country has made so many careful observations among so many diseases. There are two great types of practitioners—the routinist and the rationalist. No men among us need refreshment and renovation more frequently than those occupying positions in our schools of learning. The most hopeful feature is a restless discontent which, he hopes, may not be allayed until the revolution is complete in all respects. Meanwhile, to students who wish to have the best that the world offers, he suggests that the lines of intellectual progress are veering strongly to the West. He predicted that in the twentieth century the young English physician will find his keenest inspiration in the land of the setting sun. [A B C.]

2.—Doran found in the same subject acute and chronic **torsion of the ovarian pedicle**. On making the incision of the abdomen a cluster of cysts came into view. He passed his hand behind them and turned out the whole tumor; the pedicle was firmly twisted two turns, very edematous, and enlarged with blood. There were no adhesions, nor was there any free fluid in the abdomen. He untwisted the pedicle, ligated and divided it; the tumor, developed from the right ovary, came away. The second tumor, also made up of a cluster of smaller cysts, was then raised from behind the uterus and lifted out of the wound. Its pedicle, somewhat short, was twisted two turns, and atrophied in consequence. A low narrow piece of omentum was involved in the twist, running on to the pedicle from the left, posteriorly. The pedicle was ligated and divided; the tumor originated in the left ovary. No flushing or drainage was required, the abdominal wound was closed. In this case there were 2 pedicles, but so great was the relief from the pain caused by the torsion that the patient felt perfectly comfortable. Tumors irregular in form, are very liable to become twisted, and short pedicles are particularly subject to torsion. It has long been known that dermoids are espe-

cially liable to this complication. When there are two tumors the one may cause the other to rotate on its pedicle. Dermoids especially tend to rotate on their pedicles, partly because they are often irregular in form, and partly because they are often overweighted at one point by masses of bone or other solid, heavy structures. Acute torsion due to the contraction of the abdominal walls during defecation has been reported. In one instance the complication was caused by the patients' struggles under nitrous oxid at a dentist's. [W K.]

3.—Larkin has had 2 cases of **concealed accidental hemorrhage**. The first was in a strong, healthy woman, 7½ months pregnant; the second in an anemic, weak patient at term. Both cases became faint and suffered symptoms of severe collapse without any apparent cause. In both cases the uterus seemed to increase in size after the attack began. The liquor amnii was very scanty, pain severe, and a dead child delivered by forceps in each instance. The first patient made a slow recovery, complaining for some time of severe temporal headache. The second patient died 10 hours after the onset of the symptoms, in convulsions. [W K.]

4.—A case of **extrauterine gestation** at about mid-term was operated upon by Hellier; abdominal section revealed a dead fetus, 8 inches long, free in the abdominal cavity. The umbilical cord could be traced to the floor of the pelvis, where the placenta was lying. It was not adherent but could be easily lifted up, and the placenta was then found to be attached to the right side of the uterus, and that this attachment constituted a fairly narrow pedicle. When this was ligated and divided, and the blood-clot removed from the pelvis, it was found that hemorrhage was well controlled, and that the pelvis could be sponged dry. The abdomen was not irrigated, but a Bantock's tube was inserted, and the operation was terminated as rapidly as possible by the closure of the wound by continuous suture of the peritoneal edge by catgut, and interrupted silkwormgut sutures through the remaining layers. The patient made satisfactory progress. [W K.]

5.—Mitchell takes exception to the general belief that all cases of **septic infection in the puerperium** are due to failure to preserve antiseptic precautions in labor. He has found in a large practice extending over many years, that many of the worst cases of puerperal fever occur after perfectly natural labors in which no digital examinations or manipulations have occurred. The majority of cases which he has seen seem to him to be due to the impossibility of inducing many working people to observe the ordinary rules of postpartum cleanliness. The bugbear of catching cold leads them to neglect change of clothing and ordinary bathing. He believes that treatment with quinin will more often meet with success if the physician will push it boldly and combine its use with attention to other details. In a well-marked case of septicemia his routine is to give a preliminary dose of quinin sulfate (gr. xij). This is followed by douching of the vagina, and digital exploration of the uterus for any retained secundines. The uterus is then washed out with a weak solution of corrosive sublimate, and an Ehrendorfer's pencil of iodoform (larger than the size usually sold) is then introduced into the uterus. This is followed by a mixture containing in 8 ozs. 40 grains of quinin sulfate and 10 minims of carbolic acid, with bismuth, bicarbonate of soda, and carminatives. In cases of prolonged diarrhea tincture of opium is added. The introduction of iodoform pencils is repeated if necessary, and in suitable cases repeated vaginal douching is employed. Ice caps and cold sponging should be used when there is much hyperpyrexia. In case of sickness iced champagne and brandy can generally be retained. [W K.]

6.—Baldwin reports a case of an enormous **multilocular ovarian tumor**, occurring in a woman of 47 at the time symptoms were first noted, and 2 years subsequent to the menopause. She was first seen by Baldwin 12 years later when the tumor had attained an extraordinary size. The patient died 2 months later and he was permitted to make an examination of her abdomen. From an incision in the abdomen he drew off 114 pints of fluid. A second large cyst occupied the upper abdomen; from it 28½ pints of fluid were drawn in the same manner. At the root of these cysts were 2 smaller ones, each about the size of a coconut. The total amount of fluid obtained from the cysts was 18 gallons and he estimated the weight at 135 pounds. All four cysts sprang

from a thick fibrous base, mushroom-shaped and about 3 inches in diameter. From the under surface of this base ran a twisted pedicle about 3 inches and about the thickness of a thin umbilical cord. [W. K.]

7.—Modlin describes an operation that he performed for a curious deformity of the perineal region. The urethra, vagina and rectum all opened into a common vulva, although they were distinct except at their orifices. An incision was made through the fibrous tissue filling up the space between the rectum and coccyx. He next separated the posterior wall of the rectum for about 2 inches. The next step was to dissect up the rectovaginal septum, thus separating the 2 passages. The rectum was then detached from the surrounding tissue, so that its lower end was freely movable. It was then brought backward through the opening in its normal situation and sutured with fine silk sutures posteriorly and laterally to the skin of the perineal incision. The two flaps caused by the first incision were brought to the middle line to form the new perineum. The posterior border of this new perineum was sutured to the anterior wall of the rectum, thus completing the new anus; and the anterior border of the new perineum was sutured to the raw surface of the posterior vaginal wall, thus completing the vagina. The patient did well, and has perfect control over the bowels, the muscular fibers of the rectum having undertaken the function of the sphincter. [W. K.]

8.—Handford reports a series of 5 cases of epidemic cerebrospinal meningitis, and his results in 5 others. The most prominent symptoms, common to all, were: (1) Rapid, if not actually sudden, onset, without injury or previous failure of health; (2) the temperature rose at once to 102° to 104°, and very slowly subsided, sometimes showing distinct and regular intermissions; in 3 cases (1 fatal), the temperature remained normal for weeks, without any other sign of improvement; (3) the intensity of the pain in the head and neck, aggravated by the slightest movement; (4) marked retraction of the head; (5) muscular hypertonicity, twitching, or rigidity; (6) extreme and rapid emaciation; and (7) tendency to relapse and to intermissions. Morphine was the chief treatment that seemed to do good beyond the mere relief of pain. [A. B. C.]

10.—Burnett presents a case, illustrative of the fact that diphtheria patients may convey the disease long after they are supposed to be well. He would suggest that: (1) In the case of every boy returning to a boarding school, 2 or 3 days before the beginning of the term, both throat and nose should be bacterially tested for diphtheria; (2) in the case of any boy or person, who has recently suffered from the disease, not less than 6 months should be allowed to elapse before his return to school, and then only after a negative test has been obtained on 2 or 3 separate occasions at intervals of 1 week. [A. B. C.]

11.—Smith reports a case of conjunctival diphtheria, the chief points of interest being: (1) the cause of illness might easily have passed unnoticed; (2) infection might readily have been spread; (3) the origin of such spread would probably not have been recognized. [A. B. C.]

13.—Williams writes of his experience in treating pneumonia with morphine and Dover's powder, and other forms of opium. He believes they reduce the frequency of the pulse and quiet the nervous phenomena. [A. B. C.]

14.—Oliver reports 2 cases of procidentia uteri, the remarkable feature about them being that the patients were very young, the one being 17 and the other 16. In the first case the uterus protruded some three inches from the vulva; both were in nulliparas. [A. B. C.]

1.—See abstracts of *British Medical Journal* for July 14.

4.—Dikes, after a careful study of the subject and much experience in dealing with the diseases, has decided, contrary to his former opinion, that what is commonly termed **rubella** really consists of two diseases. He is of opinion that they are two entirely distinct processes; the one being true rubella or rose-rash, which resembles ordinary measles; the other, which he speaks of as the "**fourth disease**," on account of its resemblance to measles, scarlet fever, and rubella, resembles scarlet fever very closely, even to the desquamation. He cites an epidemic in a school which was thought to be scarlet fever, but which he found to be the "fourth disease." Another similar epidemic proved to consist of both scarlet fever and "fourth disease." Of the eruption he says that the first symptom to attract the attention of the sufferer was the rash which in nearly every case was very full and quite characteristic of scarlet fever. In fact, if 10 experts had inspected the skin and made no other investigation all would have diagnosed the eruption as that of scarlet fever. He further says: (1) That although its resemblance is so close to scarlet fever in many features it cannot possess any affinity with that disease inasmuch as both diseases occurred concurrently in the same epidemic; (2) some of the sufferers had both diseases in the same epidemic; (3) one patient had scarlet fever followed by the "fourth disease"; (4) several had the "fourth disease" followed by scarlet fever; (5) although the "fourth disease" has been confused with rose-rash and regarded as a mere variety of rubella, this conclusion is fallacious, since nearly one-half the cases in an epidemic had already had rose-rash within a year or two, which, according to Cullen's established law, is incredible; (6) he has purposely refrained from attaching a name to the disease in order to avoid the anomalous description of the same disease under an indefinite number of terms. [A. B. C.]

5.—Wright, in reporting the results obtained by **anti-typhoid inoculation** of the garrison of Ladysmith, gives a table setting forth the number of men inoculated, number not inoculated, number of attacks, deaths, etc. Out of a total of 10 529 men not inoculated, 13.2% were attacked by typhoid fever, while of 1,705 men inoculated only about 2% were attacked. The inoculation appeared to make no appreciable change in the death-rate of those attacked—it being about 22% to 23% in both the inoculated and uninoculated. He concludes that it is at present impossible to determine precisely to what extent the inoculated were protected. But the results set forth would appear to be distinctly encouraging, inasmuch as they show that the proportion attacked by typhoid fever was but $\frac{1}{4}$ as great in the inoculated as in the uninoculated. [A. B. C.]

6.—Harrison details a number of cases illustrative of obliteration of the seminal ducts by torsion, in its application to the treatment of **prostatic hypertrophy**. In cases of prostatic obstruction, without other structural complication, shrinkage of the hypertrophied prostate, however induced, speedily leads to the restoration of the function of micturition. He gives a series of 5 cases of prostatic hypertrophy treated by operation, in which the preservation of the normal function of micturition as opposed to catheter life is successfully demonstrated. In these cases, whenever the patient has had to decide between preservation of the urinary or the sexual function, he has invariably decided in

favor of the first. When structural changes in the bladder have supervened upon prostatic obstruction, and when catheter life or the necessity for it has been more or less developed, **vasectomy** does not always appear satisfactory, for the reason that although the prostate may thus be rendered incapable of obstruction, the bladder may not always regain the power of expulsion of the urine; yet, even in these cases, the lessening of prostatic obstruction has proved a great boon. When results seem to have been inadequate or negative, results still beneficial have been obtained; in these cases the patients sometimes measure the success of the vasectomy relatively to dispensing with the catheter, without sufficient regard to the other contingencies of catheter life. Harrison thinks that vasectomy is an important aid in preventing the recurrence of stone after operation, when complicated with enlarged prostate. This is probably effected by providing a free and more dependent exit from the bladder, as well as by diminishing the large amount of tenacious mucus which the enlarging prostate provokes and helps to supply. [M.B.T.]

7.—Myers mentions that there are 2 theories to account for immunity,—viz, Ehrlich's "seitenkette" or side-chain theory, and Metchnikoff's phagocytic theory—that immunity is merely a special case of assimilation. To determine, if possible, which of these is correct, the author made experiments relative to **immunity against proteids**. He took crystallized egg-albumen, serum-globulin from the sheep, serum-globulin from the bullock, and Witte's peptone, and experimented with them separately and collectively. In order to avoid the action of digestive fluids on the proteids, he introduced it directly into the peritoneal cavity of a rabbit. After repeating the intraperitoneal injections for 2 months, it was found that the serum of the rabbit's blood would form a dense precipitate when brought into contact with that kind of proteid which had been injected, while it formed a very little or no precipitate with the other proteids. The serum from the blood of a normal rabbit would form no precipitate with any of the proteid substances. The experiments are too lengthy to abstract in detail, but the author is strongly of opinion that immunity is due to a process of assimilation. [A.B.C.]

8.—Tilley contends that whatever treatment is finally adopted in **chronic empyema of the frontal sinus**, it is of paramount importance to insure free drainage from the sinus by removal of all chronic inflammatory growths from the lower end of the frontonasal canal. He advocates the removal by means of curet, snare, or forceps of the anterior half or more of the middle turbinal, of all polypi, granulations and diseased ethmoidal cells. He says that many of the failures in radical operation are attributable to the fact that external operation has been undertaken before free drainage and immunity from reinfection from the sinus have been secured by this preliminary treatment. He is not in favor of intranasal irrigation of the sinus following the preliminary intranasal treatment, claiming that it rarely succeeds, and when it does such improvement is probably due to improved drainage provided by the preliminary treatment. He strongly condemns boring into the sinus from the nose, more particularly because of the danger of ensuing meningitis; the sole method worthy of consideration, to his mind, is that of external radical operation involving removal of more or less of the anterior bony wall of the sinus of its diseased condition and the provision of free drainage into the nose. He admits that some 7 or 8 fatal cases of septic osteomyelitis have been recorded after the operation and apparently due to its performance, but claims that this must be ascribed to the fact that free drainage into the nose has not been insured at time of operation, the external wound has been tightly sewed up and, with recurring suppuration, the septic matter has been forced into the recently opened diploë of the frontal bone with ultimately fatal results. He illustrates his paper by the tabular analysis of 14 cases. [M.B.T.]

9.—Phillips reports a case of **pancreatic diabetes** due to **calculi**. The patient was a man of 50, who complained of passing blood during defecation, of a discharge in the interval which gave a greasy stain to his shirt, and of great weakness and wasting. Except for the absence of anemia he looked like one suffering from malignant disease. He had no thirst and no polyuria. The bowel movements were greasy-looking and peculiarly offensive. The urine con-

tained sugar, but no albumin. There was no jaundice. There was a history of repeated attacks of colic 20 years before. The patient gradually failed for 6 months after coming under Paillips' care, and died. Necropsy showed that the main duct and various collateral ducts of the pancreas were occluded by calculi. No communication between the pancreatic and common bile-duct or the duodenum could be found. [A.B.C.]

10.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 445.

11.—Trevithick reports a case of **Addison's disease** occurring in a man of 40. There was a strong family history of tuberculosis. The illness lasted for 2 months, the patient dying. The onset was marked by distinct pigmentation of the skin, the penis and scrotum becoming black. There was vomiting, great weakness and chilliness, the temperature being subnormal most of the time. Suprarenal extract was given twice daily without effect, though it was not used till late in the course of the disease. Necropsy showed encapsulated tuberculous deposits in the spinal column, lungs and bronchial glands. There were no signs of active or recent tuberculous processes in any organ. The substance of both suprarenal bodies was replaced almost entirely by fibrous tissue; the right was adherent to the under surface of the liver, and the left to the tail of the pancreas. [A.B.C.]

12.—Murrell reports 3 cases of **tuberculosis treated with tuberculin**. The first was a man of 41, who had been ill for 3 years. He had cough and mucopurulent expectorations containing abundance of bacilli. He was kept in bed and treated for 12 weeks, being given during that time 20 injections, varying from $\frac{1}{10}$ of a milligram to 5 milligrams. The second case was a man of 35, who had symptoms of tuberculosis for some 3 years. He was treated much as the first case, from September 12 to October 2, and was discharged. The third was a man of 45. He had had a constant cough and much expectoration for about 4 years. He had been losing flesh for over a year, but had no night-sweats. He was treated for 10 days, being given 6 injections. In none of these cases was there any improvement. The author states that his experience with tuberculin has been too limited for him to come to a definite conclusion, but so far he has had better success with the formic aldehyde treatment. [A.B.C.]

13.—De Jersey relates the case of a man of 45 admitted for **fracture of the left side of the skull** with complete unconsciousness, right-sided hemiplegia and retention of urine and feces; there was no external wound or discoloration over the seat of injury, only a slight pitting on pressure. On firm pressure over the seat of fracture, spasm of the whole right side of face and body was produced. On operation an extensive stellate, depressed, fissured, and comminuted fracture was found with a large hematoma beneath it and a cavity right into the substance of the brain large enough to admit the little finger readily and corresponding to the upper end of the left Rolandic fissure. Degenerative changes had already set in. Part of the whole thickness of the parietal bone was replaced and a gauze plug was inserted into the cavity in the brain and brought out under the flap made in operation, which was sutured and a dry dressing put on. The plug was removed on the tenth day after operation and the wound healed without suppuration. Six weeks after operation he walked quite well and carried on conversation with little difficulty, 7 weeks after operation he was dismissed from the hospital. Interesting points in the case are rapid recovery after pressure was relieved, signs of relief of pressure appearing before those of shock passed off, the comparatively late return of consciousness, and the fact that a piece of bone, including both the external and internal table, completely deprived of its periosteum, was replaced and became firmly adherent to the adjacent bone. [M.B.T.]

of Cases where the Antrum of Highmore was Involved. RUFFIN A. WRIGHT.

4. The Spectacle and the Eyeglass Habit. NORBURNE B. JENKINS.

5. Neurasthenia and Syphilis. JAMES G. KIERNAN.

6. Typhoid Fever in an Infant 18 Months Old; Recovery. A. SAMUELS.

1.—Hutchinson, in concluding his valuable article on the **pituitary body**, submits the following conclusions: (1) That the pituitary body is still functional; (2) that disturbances of its metabolism are the principal factors in both akromegaly and gigantism, the difference between the results being simply due to the stage of individual development at which the disturbance of the function begins; (3) that the nature of the overgrowth in both these diseases is primarily on the order of a pure functional hypertrophy; later, however, losing some of the definiteness of its impulse, and either producing immature tissue of a mixed type, or resulting in simple hemorrhagic exudation, with either cyst-formation or complete breaking down of the tissue mass; (4) that it seems probable, although upon this head the evidence is still uncertain, that some part is played by this body in "dwarfism," rickets, and the dwarf-forms of cretinism; (5) that a reflex disturbance of its function may possibly underlie the dystrophy accompanying pharyngeal adenoids; (6) that it would appear to be a sort of "growth-center," or proportion-regulator of the entire appendicular skeleton. [A.B.C.]

2.—Vaughan says during the past year he has treated 70 cases of **syphilitic eye affections** in private practice, and 41.4% of the cases were syphilitic manifestations of the **uveal tract** (iris, ciliary body, and choroid). Syphilitic iritis may be plastic, serous, popular, or gummatous. The author says his experience accords entirely with that of Schmidt-Rimpler, that in iritis with the formation of nodules, as a rule, true gummas are not present, but that these may appear during the later stages of syphilis, and that the tendency, with the nodules existing in the iris during the early stages of syphilis, is not destructive in character; also, that these nodules are analogous to the syphilitic condylomas and skin-papules seen during the secondary stage of syphilis. His observations have been that the symptoms of plastic and serous iritis, when due to syphilis, vary little from the symptoms of these varieties of iritis when due to other causes. Pain is one of the most prominent symptoms, and it extends sometimes over the entire half of the head, corresponding to the branches of the supraorbital nerve. The pain is usually worse at night, and is always increased by bright illumination. In several of his cases the cornea remained perfectly clear and transparent. If the ciliary body be involved in the inflammatory process to any appreciable extent, then we always have a deposit upon the posterior surface of the cornea. [A.B.C.]

3.—Wright says that **empyemas of the nasal accessory cavities** are of far more frequent occurrence than has heretofore been supposed. In a majority of all cases of acute coryza with excessive rhinal flow their presence is more than probable. They are frequent unrecognized complications of all the acute exanthems and infectious diseases where the nasal mucous membrane is involved. This is especially true of influenza, measles, and erysipelas. It seems probable that empyemas are a constant accompaniment of the first-mentioned disorder. They occur also during acute iodism, and are sometimes, though rarely, due to traumatism. Empyemas of Highmore's antrum are frequently caused by abscess at the roots of the teeth. When due to coryza, this acute implication of the accessory sinuses usually subsides with the regression of the acute catarrh, and results in perfect restoration with its subsidence. The two chief symptoms which empyemas produce are a greater rhinal flow than exists in a simple acute catarrh, usually unilateral; and more intense neuralgias than occur in a case of coryza where the sinuses are not implicated. Should the affected cavity become closed, producing a "closed empyema," the symptoms are more marked and the results may be serious. The author speaks especially of empyema in the antrum of Highmore, and its treatment. [A.B.C.]

5.—Kiernan says, **syphilophobia** is an exceedingly unpleasant symptom when it occurs alone, and doubly so when it occurs in a **neurasthenic**. Many syphilographers are of opinion that this state is easily induced in patients who have or believe they have syphilis. From a psychical point

of view this position of the syphilographers is well based. It is, however, but a negative method of psychotherapy. There is an introspective tendency engendered, whether the patient has been previously neurasthenic or not. This tendency is exaggerated if the patient has previously been neurasthenic. The problem involves the question how to apply medicinal agents without unduly giving the patient a therapeutic basis for his introspective syphilophobia. The ordinary alternatives will not answer, since one is required which will produce an emotional exaltation sufficient to offset the depression produced by the syphilophobia. For this purpose he recommends a combination of arsenic, bromids and gold (arsenauro). It should be given in 5 minim doses thrice daily, in water, and gradually increased till slight diarrhea is produced. [A.B.C.]

6.—Samuels reports a case of **typhoid fever** occurring in a female **infant** 18 months old. The temperature ranged from 103° to 105°, and the fever lasted for 20 days. There was entire absence of the common symptoms of typhoid fever. There was extreme anemia, and aphasia which lasted some 10 weeks after recovery. Widal's reaction was present. [A.B.C.]

Medical Record.

1. Chorioepithelioma Malignum. B. S. TALMEY.
2. Hypospadias Operated on by Beck's Method. FERD. C. VALENTINE.
3. The Peritoneum—Anatomy, Physiology, and Pathology. BYRON ROBINSON.
4. Amenorrhea. I. H. DUNNING.

1.—In July, 1899, a woman died at Zurich with the clinical diagnosis of anemia. She was delivered in April and had had following her confinement, a light bloody discharge. The rough, papulous, lacerated appearance of the surface of the uterine mucosa of the posterior wall gave the impression of the placental site preserved three months and led to a close examination of the specimen, disclosing a typical **malignant chorioepithelioma**. By far the greater part of the tumor appeared to be the pure product of a coagulation as described by Marchand, and which he considers the first stage in the formation of the tumor. Talmey disagrees, however, thinking it the last stage. Hyalin degeneration is generally a sign of degeneration and not of proliferation. In the case under study Talmey was of opinion that the large ectodermal cells stand mainly in close relation to the formation of the fibrin. He failed to recognize true chorionic villi anywhere, yet the glandular epithelium changed into syncytium, in opposition to the views of Marchand, Selenka, and Kossman. This atypical formation shows the malignancy of the tumor—the glands continue to furnish syncytium as an investment for villi that are no more in existence. [M.B.T.]

2.—Valentine describes a case of **penile hypospadias**, the urethra opening a half inch below the glans, in which he operated successfully by the method originated by Carl Beck of New York. He rehearses the proofs of Dr. Beck's priority and deprecates the prevailing tendency among notoriety seekers of "originating" methods, operations and instruments already fully described. [M.B.T.]

3.—Robinson decides from his experiments and the result of the work of others, that the primary path of **absorption from the peritoneum is by the lymphatics**, the stream passing toward the diaphragm and the diaphragm acting as a suction pump. He considers the diaphragm the primary locality of absorption of solid matters from the peritoneum. Because absorption is so much more active near the diaphragm, peritonitis is more dangerous to life as it approaches the diaphragm. The leukocytes seem to be active in carrying formed particles into the subperitoneal diaphragmatic lymphatics. The injection of potassium ferrocyanid into the peritoneal cavity is much more readily followed by its appearance in the urine if the thoracic duct is not ligated than if it is ligated; hence open lymphatics aid its appearance in the urine. He considers that the leukocytes act as the chief guard of the peritoneum. He mentions the results of the injection of water containing Berlin blue into the peritoneum of a turtle. The animal died within 4 or 5 weeks of peritonitis. Autopsy showed edematous and vascular peri-

toneum, with desquamation of the endothelial cells, exudation of leukocytes and of red blood-cells. He speaks emphatically of the importance of the psoas muscle and of the diaphragm in causing trauma of the peritoneum covering the bowel and the spleen, thus producing peritonitis. There is a description of the various forms of peritonitis and of the surgical treatment of these. [D L E.]

4.—Dunning mentions tuberculosis and Bright's disease as among the common causes of amenorrhea, and says that the prevalent idea that amenorrhea causes tuberculosis is most fallacious. He discusses the general and local causes, since he believes that any efficient treatment of amenorrhea must be based upon the correct knowledge of the lesion producing the disease. He emphasizes the fact that active efforts by the administration of powerful emmenagoges are harmful, especially in cases of Bright's disease and tuberculosis; for such a course is liable to result in congestion of the pelvic organs and the development of new and distressing symptoms; and all efforts to restore the function will be unavailing unless one can arrest and overcome the ravages of these diseases. Amenorrhea following acute and debilitating diseases need not as a rule occasion the serious apprehension of physician and patient. Here the chief end should be to restore the health of the patient after the intensity of the attack has passed. In anemic, overgrown girls, or in chlorotic cases, food rich in blood-making properties should be directed and a high state of activity of the digestive and assimilative functions maintained; and the bowels, skin, and kidneys should be kept in an active and normal condition. With the disappearance of anemia and the oucoming of good health, the menstrual function is, as a rule, established. If it is not, mild emmenagoges are often beneficial. Potassium permanganate in one and two-grain doses is quite efficient. [W K.]

2. Headache from Eye-Strain; Its Diagnosis and Treatment. CASEY A. WOOD.
3. A Contribution to the Management of Face-Presentations. MALCOLM McLEAN.
4. Acute Trional Intoxication. WARREN COLEMAN.

1.—Bryant recites the treatment in a case of acute traumatic empyema. The patient was a man of 24 who, by accident, had a blunt instrument thrust through the thoracic wall at a point just below the right nipple. The pleural cavity was opened, but the lung was not injured. The wound was treated surgically, enlarged, and the pleural cavity flushed out with normal salt-solution. From the nature of the wound and the penetrating object, infection was inevitable. A rubber tube was inserted for drainage and allowed to remain, but it was found when the syringe was applied to this and the pus withdrawn that the change in atmospheric pressure set up violent coughing. Consequently the tube was packed about at the wound so that air could not enter there, and provided with a stopcock so air could not enter through the tube. Now the syringe could be used, followed by applying a collapsed rubber bag to the end of the tube. This, with the cock properly arranged, would not only prevent the entrance of air, but would gradually drain out the pus and other accumulated fluids. It was found, however, that not too much of the fluid could be withdrawn at one time, for the pressure from within caused some hemorrhage from the lung, as shown by a staining of the removed fluid. The patient was soon able to manage the apparatus, and made a good recovery. Illustrations accompany the article, and a review of the literature bearing on the subject is carried to some length. [A B C.]

2.—Wood defines ocular headache as those aches and pains in and about the head that directly or indirectly result from organic disease in, or from impaired function of, any part of the visual apparatus. He is of opinion that with a little care and patience the general practitioner may differentiate between the headache due to eye-strain and that due to other causes. The author thinks that 40% of all headaches are caused wholly or partially by eye-strain; and further, that 80% of frontal headaches are produced in this way. He

subdivides these pains into supraorbital, deep orbital, fronto-occipital, and temporal. A severe headache after a shopping excursion, or a ride in a train or street-car with its ever-changing views, is an almost sure sign of eye-strain. Astigmatism is probably the most frequent cause of headache from eye-strain. The visual test-card, the astigmatic chart and Pray's astigmatic letters, the author thinks, are the most effective tests for astigmatism which the nonspecialist can employ. Insomnia and dyspepsia may cause disease of the eye. [A B C.]

3.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, No. 18, page 996.

4.—Coleman considers trional one of the safest and most useful hypnotics we possess. He has seen but one instance of trional poisoning. In this case the woman took through error 9 drams of trional in 72 hours; it caused somnolence, with disturbance of respiration and of circulation, some feeling of dizziness, and an ataxic gait. Judging from this case he considers trional devoid of any decidedly depressive action on the circulatory or respiratory functions, and experimentation supports this. These statements have no relation to the effect of trional when used over a long period. [D L E.]

3.—Norbury thinks a chief etiologic factor in post-febrile insanity is abnormal metabolism. Heredity bears a tentative relation, in providing a neurotic weakness and physical instability easily influenced by febrile diseases. Residence is a factor only as regards location being favorable to the production of febrile disease. Compared with cases of insanity following autointoxication from other sources, there is a wider range of alienation following fevers. The severity of the attack has apparently no relation to the severity of the febrile attack. It may also vary in its time of appearance. The diagnosis is not difficult, especially when following typhoid fever or erysipelas. Blood-count, microscopic study, and urinary analysis are of great aid. Prognosis should be guarded, although recovery is usual in the average case. In treatment, among other means, are recommended rest, massage, elimination by brisk use of aperients, diuretics and cathartics, and the plentiful use of water internally and externally. When sedatives are absolutely necessary opium and hyoscyamus are best. Tonic

treatment by iron, arsenic and strychnin is valuable. [M.B.T.]

4.—Benedict reviews the **physiology of the digestive organs**, considering in detail certain points seldom elaborated in textbooks, as for instance the amounts of free or combined HCl, and of total acidity to be expected under normal conditions. He speaks of the fallacy of the lactic acid test for the existence of carcinoma, and discusses various means for determining the rate of gastric peristalsis, etc. [M.B.T.]

6.—“ “ “ “ Vol. V, p. 1282.

7.—“ “ “ “ Vol. IV, p. 19.

8.—Shober uses **mammary gland** in tablet form made of the desiccated gland of sheep. Each tablet represents 20 gr. of fresh gland. The dose is from 3 to 6 tablets daily. While it has no unpleasant systemic effects, it seems to act on the uterus, causing contraction, diminishing the blood-supply, and controlling bleeding. Its action is similar to ergot and in his experience more reliable and can be used over much longer periods of time without causing unpleasant symptoms. In uterine fibroids with menorrhagia bleeding can be brought under control in a few weeks, and, if the treatment is persisted in, the menstrual periods become regular and normal and unaccompanied by clots and pain. The health improves commensurately and the tumors diminish in size up to a certain point. Shober believes it possible that constant use of the mammary gland by these patients will indefinitely postpone the necessity for operation in many instances. He has also used the gland with success in many cases of subinvolution. These are the only classes of cases in which he advises the use of mammary gland and yet some men use it in cancer, dysmenorrhea of ovarian or tubal origin or due to malpositions of the uterus, and even in dysmenorrhea due to stenosis and in cases of amenorrhea, though there seems to be no indication for its use. Parotid gland he has used in a much smaller class of cases. It is prepared in the same way, from the sheep, and should be employed in about the same doses as the mammary gland. Its principal action is power to control ovarian pain and Shober has employed it with satisfaction in ovarian neuralgia. These agents should not be used if gross structural changes are present. [M.B.T.]

9.—Purdy has investigated a series of cases to determine if it is possible to predict in what cases **interstitial nephritis** is likely to develop. Of several hundred acquired cases which he has recorded, the dominant features of the vast majority were heavy appetites, sedentary lives, and excessive use of proteid foods, or overingestion and over-elimination of nitrogen. Hence in cases in which we have reason to fear the establishment of interstitial nephritis, the limitation of proteid foods should constitute our first and most essential principle in the establishment of prophylaxis. Meat should be limited to one meal a day and the quantity should not exceed a quarter of a pound. The leguminous vegetables, such as beans, peas, lentils, etc., should, for the most part, be avoided. Sugar should be sparingly permitted. The appetite should be restrained within normal limits, and systematic daily exercise should be advised in order that the proper ratio of waste products of the economy may be oxidized with the least strain upon the eliminative functions. In people who have led sedentary lives active exercise should be prescribed with discretion and it is best to begin with passive exercise and massage. After the disease is once established the diet should be still more strictly limited and special care should be given to the condition of the heart. If there is tendency to hypertrophy, non-nitrogenous diet and saline laxatives will cause it to subside rapidly. If the urine falls in volume and the pulse grows weaker the indications are to improve the tone and nutrition of the heart, and to relieve it of as much labor as possible. The small vessels should be dilated by means of the iodids and nitrites. Moderate doses of digitalis tend to improve cardiac nutrition and tone, especially when assisted by the use of strychnin. Absolute quiet should be enjoined for from 4 to 6 weeks, until the heart has regained its tone, or is in a measure equal to its work. Then a course of cardiac gymnastics, after Schott's method, with, or followed by, the Nauheim baths, is often of the greatest benefit. [M.B.T.]

4. The Diagnosis and Treatment of Pulmonary Tuberculosis. II. SENATOR.
5. An Unusual Case of Acute Anterior Poliomyelitis in the Adult Resulting from Infection. KARL GUMPERTZ.

1.—A review of the development of the theory of **mitotic cell division** with which the author's name is prominently connected. Although the discoveries in this field have been important and remarkable, the ultimate cause of cell division has remained as much a mystery as it ever has been. [D.R.]

2.—The **method of examining candidates** for the sanitarium at Grabowsee is as follows: The patient having stripped to the shoulder girdle, the chest is inspected and percussed, finger percussion being employed. For percussion of the lung apices, the patient sits in a chair, stooping slightly forward and holding his hands in his lap. The examining physician stands behind the patient. In auscultation particular attention is bestowed upon the supra- and infraclavicular and supraspinous fossæ. In order to detect fine differences of resonance, percussion is practised with the chest not only in the median position, but also in extreme inspiration and extreme expiration. [D.R.]

4.—Small **pulmonary hemorrhages** usually stop with a rest in bed. When the hemoptysis is marked the diet must be nonirritant and reduced. An ice-bag on the chest may be employed; its value is doubtful. Ergot is, according to Senator, of no value, and may possibly do harm by raising the pressure in the vessels of the lung, although such action is doubtful. He prefers extract of hydrastis, hamamelis, or stypticin. Acetate of lead may also do good. The use of gelatin injections, if they cause pain, may do harm; gelatin may be given by the mouth, and is, moreover, a good food. Morphin is a valuable remedy. When the heart's action is excited and is not subdued by the ice-bag, Senator gives digitalis as well as morphin. There are three other agencies which are briefly referred to:—the bandaging of the limbs, the inhalation of astringent remedies, and milk of alum. None of them is very efficacious, probably. For the phthical fever and night-sweats it may often be sufficient to have the patient take a spare meal at night, avoiding wine, tea, and coffee. When the fever lasts the whole day pyramidon has given good results. Ablutions, especially with camphor and menthol-water, do good. The best results are obtained, however, with the external application of guaiacol, beginning with 0.5 gram. For the night-sweats, in addition to sponging with water, vinegars, or aromatic solutions, Senator recommends inunctions of fat or bacon; or the skin may be painted with a formalin solution. Internally atropin, agaricin, camphoric acid, and sodium tellurate (.02 to .05 grams) have been employed. Picrotoxin, sulfonal, and caïotin have at times an influence. [D.R.]

5.—The patient, aged 23, always healthy, was seized after an attack of gastric fever with a unilateral, flaccid palsy of the muscles supplied by the upper part of the brachial plexus, as well as paresis of the leg on the same side, with loss of knee jerk. The paralysis was atrophic, but gradually improved with the exception of that in the deltoid muscle. The author considers the case one of **acute anterior poliomyelitis** of infectious origin, probably due to the typhoid poison. [D.R.]

Poisoning by Stramonium.—Duncan G. Newton (*Quarterly Medical Journal*, for Yorkshire and adjoining counties, June, 1900) reports 2 cases due to infusion of the leaves taken under lay advice to relieve asthma; in both cases there was delirium, dilated pupils, flushed face, small and rapid pulse, followed by deep narcotization. In the first case strangury existed. It was difficult to produce emesis, ordinary means failing and it required the administration of one-fifth of a grain of apomorphin to produce vomiting. [M.B.T.]

Original Articles.

MORBID CONDITIONS CAUSED BY THE *BACILLUS AEROGENES CAPSULATUS*.

The Shattuck Lecture.*

By WILLIAM H. WELCH, M.D.,

Professor of Pathology, Johns Hopkins University.

ALTHOUGH the subject which I have chosen for this lecture relates for the most part to infrequent affections, the scientific and practical interest attaching to them is considerable and varied. Many instances of the presence of free gas in parts of the body where it does not normally occur and in association with various diseases were recorded by writers of past centuries and were even then the subject of much speculation. The discussion turned generally around the question whether the gas was atmospheric air or the result of putrefaction—a question which in most cases could be solved only by bacteriologic examinations. The most numerous and important of such examinations have been made during the last decade, and, although these have left problems still unsolved, they have corrected many current errors and have shed a flood of light upon conditions which were formerly among the most mysterious in pathology.

While it has been demonstrated that various bacteria may be concerned in producing gaseous affections, it is now evident that the bacillus which I discovered in 1891 and to which I gave the name *Bacillus aerogenes capsulatus* is the one whose causative agency is best established and most frequently in action. What I shall say will relate mainly to this microorganism and its pathogenic effects.

Historic.—As a certain amount of confusion concerning the dates of the first publications¹ on this bacillus exists in foreign literature on this subject, it may be well to state that I reported my observations in November, 1891, to the Johns Hopkins Hospital Medical Society and that the full report of these observations and of the characters of the bacillus was published in July–August, 1892, by Dr. Nuttall and myself.² E. Fraenkel's first publication³ was a short preliminary one which appeared in January, 1893, and was followed in the same year by his valuable monograph on gaseous phlegmons.⁴ In August, 1893, one year after the publication of the paper by Nuttall and myself, appeared simultaneously the interesting articles of P. Ernst⁵ and of Graham, Steward and Baldwin.⁶ Early in 1894 Mann published from my laboratory an observation of emphysematous gangrene caused by *Bacillus aerogenes capsulatus*,⁷ and in January, 1896, Dr. Flexner and I published an extensive paper reporting 23 human cases, including not only 6 personal observations of emphysematous gangrene, but also examples of submucous gas cysts, pneumo serositis, and various other pathogenic manifestations of this bacillus.⁸ In July, 1895, appeared Goebel's preliminary communication,⁹ and in the following year his full paper on the bacillus of foamy organs.¹⁰ Of the subsequent records the most numerous and valuable have appeared in this country, although they appear to be little known to most European writers.¹¹ I shall have occasion to refer later to many of these publications.

Nomenclature.—Dr. Fraenkel has kindly favored me

with cultures of the bacillus which he cultivated from gaseous phlegmons, and to which he gave the name "*Bacillus phlegmones emphysematosae*." There can be no question whatever as to the identity of his bacillus with our *Bacillus aerogenes capsulatus*, a point upon which we are both agreed, and which is also made certain by Goebel's studies under Fraenkel's supervision. According to the generally accepted principles of the nomenclature of zoological and botanical species the latter name, as being the first one applied, should be preferred to the former. It is, moreover, as pointed out by Muscatello, not open to the objection of implying exclusive relationship to a single disease, as is the case with Fraenkel's designation of the bacillus. As a matter of fact the capacity to produce gaseous phlegmons is only one of many pathogenic manifestations of *Bacillus aerogenes capsulatus*. Unfortunately I think that we both erred against the canons of botanical nomenclature in using a trinomial rather than a binomial name for a species.¹²

Characters of Bacillus.—Since our first publication only one material addition has been made to the extended description given by Nuttall and myself of the morphological and cultural characters of *Bacillus aerogenes capsulatus* or the gas-bacillus, as I shall briefly call it.¹³ Fraenkel noted the presence of spores in a few of the bacilli growing in one lot of agar containing sodium formate, and in 1897 Dunham¹⁴ observed spores in blood-serum cultures, but not in other media.

Our further studies of the gas bacillus obtained from different sources have shown a moderate range of variation in some of its properties. This is true especially of spore-formation, rapidity of liquefaction of gelatin, presence of capsules, retention of Gram's stain, and virulence. While some specimens of the bacillus seem never to form spores on any culture-medium, others, and these appear to be the more common, do so occasionally, especially upon blood serum, in mannite bouillon, and on plain agar. In animals inoculated with pure cultures we have not observed spore-bearing bacilli.

As a rule the bacillus liquefies gelatin slowly, but some specimens do so scarcely at all, and others with fair rapidity.¹⁵

As stated in our original article capsules are not constantly present, but I have generally found no difficulty in demonstrating them in the situations and by the method described by us, and, with the exception of Hitschman and Lindenthal, most other investigators have been able to demonstrate capsules, when these are searched for by suitable methods.

While the bacillus is to be ranked among those which stain by Gram, it is sometimes rather noticeable in cover-slips from cultures that among well-stained bacilli, others are partly or wholly decolorized, and this may be observed in members of a single chain. In the tissues the bacilli stain well by Gram. Differences in the viability of cultures were pointed out in our first paper.

It sometimes happens that original cultures from human beings show only a feeble growth, with relatively weak power of gas-production, while subsequent cultures, especially those obtained after passage through the animal body, present the usual vigorous growth and other typical characters. Pratt and Fulton¹⁶ from a typical case of foamy organs with gas throughout the body were unable to cultivate the bacillus at all, although twelve anaërobic culture-tubes containing various media

* Delivered before the Massachusetts Medical Society, June 12, 1900.

were inoculated from different parts of the body. This negative result they attribute to the fact that the body had lain in a cold storage vault for sixteen hours after death, an explanation which has some support in an observation previously reported by Welch and Flexner, but still seems hardly satisfactory, as under similar conditions the bacillus has been often cultivated.

Lactose, glucose, and saccharose are all fermented by the gas-bacillus, the first with the largest production of gas and the last with the smallest. There is apparently no fermentation of mannite, at least the gas is not appreciably more than in sugar-free media. The amount of hydrogen greatly preponderates over that of carbon dioxide.

E. Fraenkel, in 1893, was the first to demonstrate the etiologic relation of the gas-bacillus to gaseous phlegmons, our previous investigations being concerned mainly with the so-called foamy organs (*Schaumorgane*) and the presence of gas in the blood, our results being confirmed a year later by P. Ernst. Soon after Fraenkel's publication we were able to confirm his discovery of the causation of gaseous phlegmons by *Bacillus aerogenes capsulatus*, and to repeat with similar results his animal experiments.

Material or cultures fresh from the infected body are usually highly virulent for guineapigs, pigeons, and sparrows (E. Fraenkel), which succumb to a rapidly spreading local necrosis of the tissues with abundant development of gas, the bacilli invading the blood during life only in a small number or not at all. There is more or less bloody edema, but otherwise little inflammatory reaction, leukocytes being present usually only in small numbers in the exudate. Rabbits and mice, while not wholly immune, are far less susceptible than guineapigs and pigeons. Dr. Lanier in my laboratory in 1896 succeeded in producing typical gaseous phlegmons around the fractured bones of rabbits inoculated intravenously with pure cultures, and Muscatello has obtained the same results. Welch and Nuttall reported an instance of death of a pregnant rabbit after intravenous injection, the infection with the gas-bacillus originating in a dead fetus. There are considerable differences in the degree of virulence of the bacillus even in fresh cultures, and old ones may be of very slight virulence.

One of the most interesting and valuable tests of the gas-bacillus is its power of producing gas abundantly in the blood, organs, and tissues of rabbits killed a few minutes after intravenous injection, a power not possessed by colon-bacilli. The differential value of this test is as great as that of cultures in fermentation-tubes. The blood and tissues of the dead rabbit make the culture medium, the body of the animal takes the place of the test-tube, the inoculation is an aseptic one, the bacteria are spread by the blood-current and the conditions are anaërobic. This procedure, which was introduced by Nuttall and myself and has been fully described by us, we have found useful in isolating the bacillus, in separating it from other bacteria which may resemble it, and in the demonstration of one of its most fundamental characteristics, namely, the power to produce gas from proteid material.

Among the points distinguishing the bacillus of malignant edema from *Bacillus aerogenes capsulatus* may be mentioned the following: The malignant edema bacillus is somewhat thinner, has greater tendency to grow into filaments, is less readily stained by Gram, produces spores regularly in culture-media, is motile,

liquefies gelatin more rapidly, produces a foul odor, produces less gas in lactose bouillon, peptonizes clotted casein, generates little or no gas in rabbits inoculated intravenously and then killed, and by subcutaneous inoculation in susceptible animals causes spreading bloody edema with little or no development of gas-bubbles, and appears after death in filaments on serous surfaces.

The bacillus to which Lindenthal¹⁷ has quite unnecessarily given the name *Bacillus emphysematis vaginæ* is doubtless identical with *Bacillus aerogenes capsulatus*. The same is true of Veillon and Zuber's¹⁸ *Bacillus perfringens* found by them in appendicitis, by Guillemot¹⁹ in gaseous gangrene and by Sonpault and Guillemot²⁰ in gaseous abscesses, and of Buday's²¹ *Bacillus cadaveris butyricus*, found in foamy organs. I am strongly inclined to the opinion that the anaërobic bacillus isolated by Achalmé and others from several cases of acute articular rheumatism and found by Savtchenko and Mielkich in the soil is likewise identical with our gas bacillus.²²

Distribution.—The surmise expressed by Welch and Nuttall that the gas-bacillus is widely distributed in nature has since been confirmed. The natural habitat of the organism is the intestinal canal and the soil, the home of so many other anaërobic bacteria. Welch and Flexner, in 1896, brought evidence of the presence of the bacillus in both of the situations mentioned. Clifton of the Johns Hopkins Hospital has found the bacillus twice in the appendix vermiformis. Howard²³ has recently reported the presence of morphologically identical bacilli in the intestines of 25 consecutive human cases examined *post mortem*, and in 10 of these he demonstrated the bacillus by cultures and inoculation of animals. The same conclusion has been reached by Hirschmann and Lindenthal. The gas-bacillus has been repeatedly cultivated from the intestine in my laboratory, but we have made no systematic study of the frequency of its presence. I have found the bacillus also in the intestines of rabbits, dogs, and swine, and here it is interesting to note the frequency with which submucous gaseous blebs are found in the pig's intestine at autopsy.

In 1896, Dr. Walker, at the Johns Hopkins Hospital, succeeded in finding the gas-bacillus in dust collected by sweeping floors, proving its presence both by cultures and animal experiments. My assistant, Dr. Harris, has cultivated the bacillus from the contents of an old cesspool. I had previously reported in 1896, the isolation of the bacillus from a bullet removed from the head of the tibia in a case of gaseous phlegmon, and E. Fraenkel²⁴ has cultivated the gas-bacillus from a splinter of wood extracted from a wound in a case of tetanus. These observations confirm the natural inference to be drawn from the study of cases of traumatic emphysematous gangrene, in most of which the source of infection is manifestly foreign material, especially dirt, in wounds. In the light of these demonstrations of the wide distribution of the gas-bacillus in the outer world and in feces, the conclusion is warranted that it must occasionally be present upon the human skin.

We are not informed whether there are differences in the regional distribution of the gas-bacillus. The fact that during the last decade a larger number of cases of emphysematous gangrene have been reported from Baltimore than from any other single locality is due, probably, to our interest in the subject and consequent search for cases. The bacillus has been found not only

in America and Europe, but Dr. Flexner has brought back reports of 3 infections with the gas-bacillus in Manila observed during a stay of 3 months.

GAS-BUBBLES IN THE BLOOD AND ORGANS.

We turn now to the consideration of the various conditions in which the gas-bacillus has been found in human beings. We need not pause to consider the presence of this bacillus in ordinary cadaveric decomposition, a circumstance sufficiently explicable by the occurrence of this organism in the healthy intestinal canal.

Of an entirely different nature are the cases in which gas-bubbles are found in the blood and organs within a few hours after death and without any trace of ordinary putrefaction. Such a condition has been recognized at autopsies as soon as 1, 2, 3, 5, 8 hours after death. It may occur not only after death from gaseous phlegmon, when, however, it is by no means constant, but also after death from the most varied causes. It has been observed repeatedly in autopsies on pregnant and puerperal women, especially after death from abortion, operation for placenta praevia, and acute sepsis. There is every gradation from cases with a few bubbles of gas in the blood or tissues to those with extensive emphysema of the organs and tissues. The term "foamy organs" (Schaumorgane of the Germans) may be applied to the latter condition. The liver is the organ most frequently the seat of early and abundant development of gas, but there is no definite rule as to the distribution and amount of gas in different cases. As will be explained later, the invasion in the majority of cases is from the intestine. That the gas-bubbles may be dislocated from their original position in liquid and soft material in the body is self-evident, but I have not found them unassociated with gas-bacilli.

Formerly this early presence of free gas in the heart and vessels, without evident postmortem decomposition, was very generally explained by the assumption of entrance of air into the circulation, even when no portal of entry could be found.²⁵ The most extensive application of this explanation was made in the pregnant and puerperal cases. It is remarkable that the first case of this nature to be examined bacteriologically was that reported by me in 1891. In this and in all subsequent similar cases with satisfactory bacteriologic examination *Bacillus aerogenes capsulatus* was found.

The main questions which arise concerning the interpretation of these cases are whether the invasion of the bacilli and whether the development of the gas are antemortem or postmortem phenomena.

Rabbits survive the introduction of large numbers of gas-bacilli directly into the circulation, unless there exists somewhere in the body necrotic or damaged tissue offering little or no vital resistance. If the animal be killed within a few minutes after the intravenous injection of the bacilli and kept in a warm place, there are abundant multiplication of the bacilli and large development of gas throughout the dead body within the space of six or eight hours; whereas if the bacilli be introduced at one point, as for example the right heart, of a rabbit just killed, it takes a much longer time, often twenty-four to forty-eight hours, for gas and bacilli to make their appearance at points far distant from the seat of inoculation. It seems justifiable to draw from these three groups of experiments, which have been fully reported by Welch and Nuttall, the conclusion that when bacilli and gas are found within

a few hours after death widely distributed in the body, the gas-bacilli have entered the circulation during life, but probably in most cases only shortly before death.

There is one factor, however, to be considered, which is absent in the experimental cases and may be present in human beings, to wit, the quick disappearance of the bactericidal power of the blood. This factor is an important determinant of the rapidity of onset of post-mortem decomposition. After death from certain diseases, and particularly from snake venom, bacteria may make their appearance in the blood and organs very soon after death. An explanation of these cases is furnished by the experiments of Ewing and myself,²⁶ which demonstrated that the blood of rabbits killed by rattlesnake-venom is practically devoid of bactericidal power, so that immediately after or even shortly before death bacteria can start growing in the body as they would in a tube of beef-broth. But after all due allowance has been made for the possible reduction or loss of bactericidal power of the blood, I still consider that it is not possible to explain some of the cases in which bacilli and gas have been found in the heart, bloodvessels, and organs very soon after death, especially when the corpse has been kept in a cold place, otherwise than upon the assumption of the distribution of the bacilli by the circulating blood.

It is another question whether gas as well as bacilli may be present in the circulating blood and internal organs during life in the class of cases now under consideration, and I regret to be unable to furnish a positive answer to this question. I do not see how an affirmative answer can be obtained otherwise than by the actual demonstration of gas in these situations either during life or immediately after death. Gas-bubbles and bacilli have been found in the heart and vessels within an hour after death, but that is time enough for bacilli which have already been introduced to multiply and begin to form gas. I at first thought that absence of nuclear staining around the gas-bubbles and masses of bacilli might serve as an indication of their presence during life, and this view is advocated by P. Ernst, but I have since learned from experiments on rabbits that this is not a decisive criterion, although often both in rabbits and human beings there is no defect in nuclear staining around bacilli and gas-bubbles.

I know of no other pathogenic microorganism which offers such difficulties in determining whether its effects in the interior of the body have been produced before or after death. The difficulty arises from the circumstance that these effects in most cases and most situations consist almost entirely in local necrosis and formation of gas, whether the invasion and growth of the bacilli be before or after death, and that unlike most pathogenic bacteria the gas-bacillus grows better in the dead than the living body. Possibly some importance in the solution of the problem may attach to the demonstration of emboli of liver-cells and of bone-marrow cells which were in enormous numbers in the pulmonary vessels in a case of gaseous phlegmon of the submammary tissues following infusion of salt-solution. At the autopsy made by Dr. Carroll the liver and other organs were emphysematous. Further observations with reference to these emboli in this class of cases are needed.

I do not consider that there is any inherent improbability in the supposition that gas-bubbles may be in

the circulating blood during life without causing speedy death from gaseous embolism. It is only when a large volume of air is introduced quickly into the blood-current that sudden death results from air embolism. Very exaggerated ideas have prevailed among physicians as to the dangers from the entrance into the circulation of small quantities of air. Laborde and Muron²⁷ injected into the external-jugular vein of a dog 1120 cc. of air in the space of one hour and a half without causing death, and Jürgensen²⁸ into the left femoral artery of a narcotized dog weighing 43½ kilo 3650 cc. in the space of two hours and twenty-five minutes with only slight disturbance of the respiration and of the action of the heart. Hare²⁹ likewise on the basis of experiments controverts current beliefs in the dangers from entrance of air into the veins.

I have come across, in the older literature from the days when venesection was a common practice, reports of cases in which blood containing bubbles of gas escaped during venesection from veins of the arm.³⁰ In none of these was there evidence that air had gained entrance to the circulation. Maisonneuve³¹ in incising two gaseous phlegmons of the thigh following compound fracture observed the escape of blood containing gas-bubbles from the cut veins and was able to trace the gas within the veins for a long distance.

It seems to me very improbable that an anaërobic bacillus, such as the gas-bacillus, can multiply in the circulating blood; still this bacillus is less sensitive to the presence of oxygen than many anaërobes, and we do not know whether the loose combination in which oxygen is present in the blood would necessarily prevent its growth under all circumstances.

I see no reason why this bacillus might not multiply in the liver, spleen, and most other internal organs, as we know it can do in parts open to inspection during life. We have positive evidence in the cases reported by Graham, Steward and Baldwin, and by Dunham that gas-bacilli may be conveyed by the circulation from an infected portal of entry, in the one case the puerperal uterus and in the other a urethral wound, to distant parts of the body and there produce subcutaneous emphysema and necrosis. There is no part of the body which offers such favorable conditions for the postmortem growth of the bacillus as the liver, probably on account of its content of carbohydrate, and if the liver, like the integuments, were open to inspection during life, I believe that we should find evidence that in certain cases the emphysema of this organ, which is such a conspicuous postmortem phenomenon in instances of invasion by the gas-bacillus, had begun during the life of the patient. Emphysema, due to gas-bacilli, of mucous membranes, open to inspection, we know can exist during life. This subject will be considered subsequently.

In the great majority of the instances, however, in which gas-bubbles are found in the blood and internal organs at autopsy, the evidence is in support of the view that the development of the gas is a purely post-mortem phenomenon. Certainly the greatest caution should be exercised in the interpretation of any such cases as vital processes, even in early autopsies without ordinary putrefaction.

One thing which our investigations have established is that the finding of gas-bubbles in the bloodvessels and heart within so short a time as one hour after death furnishes in itself no proof of the entrance of air into the circulation. I shall refer later to the question of

gaseous embolism in cases of emphysematous gangrene and of physometra.

EMPHYSEMATOUS GANGRENE.

In a few instances we have found in wounds, usually compound fractures or gunshot injuries, in which dirt had gotten in, *Bacillus aerogenes capsulatus* without the presence of gas or other evidence that the bacillus was producing any characteristic effects.³² Such cases have always been watched by the surgeons with anxiety, and it is probable that at least in some the early recognition of the bacillus, followed by free incisions and thorough cleansing and disinfection, has warded off a subsequent grave infection. In view of the wide distribution of the gas-bacillus in the outer world, and in the intestinal contents, it is probable that it must not so very infrequently gain access to wounds without securing a foothold. While this innocent behavior, with which we are also familiar in the case of the tetanus bacillus, may sometimes be due to attenuated virulence of the bacillus, it is probably oftener attributable to accessory circumstances, such as the resistance of the patient, the condition of the wound and surrounding tissues, and lack of association with other micro-organisms and foreign substances.

It is as a cause of that most dreaded of wound complications, emphysematous gangrene, that *Bacillus aerogenes capsulatus* especially claims the interest of surgeons. The classical clinical descriptions of this disease we owe to Maisonneuve³³ and to Pirogoff,³⁴ the former giving to it the name "gangrène fondroyante," and the latter designating it "primary mephitic gangrene" or "acute gangrenous edema." Among other more or less common designations are "emphysematous or gaseous gangrene," "gaseous phlegmon," "septic emphysema," "érysipèle bronzé" (Velpeau), "progressive gangrenous edema," "gangrenous septicemia," and "emphysematous cellulitis."

This wound-complication was more common in pre-antiseptic times, especially in military surgery, than it is today, but at least 70 cases have been reported during the last quarter of a century. In prebacterial days the affection was attributed by some writers to the penetration of air into the tissues, but by most to the decomposition of the tissues, particularly of adipose tissue and bone-marrow, brought by an injury into contact with the atmosphere.

Bottini³⁵ in 1871 was the first to demonstrate the infective nature and transmissibility of emphysematous gangrene. Later, Gussenbauer also recognized the disease as a definite infection, and attributed it to the bacteria of putrefaction. After Pasteur's discovery in 1877 of his "vibron septique," more commonly, since Koch and Gaffky's investigations, designated *Bacillus œdematis maligni*, and especially after Chauveau and Arloing's³⁶ paper in 1884, cases of emphysematous gangrene have been usually reported, especially in France, as instances of Pasteur's gangrenous septicemia or Koch's malignant edema. W. Koch's³⁷ attempt to identify the disease with symptomatic anthrax (Rauschbrand) was based on faulty bacteriologic studies and has met with no confirmation. In 1884, F. J. Rosenbach³⁸ reported finding in cover-slip specimens from two cases of traumatic emphysematous gangrene, coarse bacilli, some of which had terminal spores. These emphysema bacilli, as he calls them, he was unable to cultivate, only aerobic methods being employed. It is probable that

Rosenbach saw *Bacillus aerogenes capsulatus* in these cases, but without distinguishing it from associated spore-bearing bacilli.

A critical examination of the records of alleged malignant edema in human beings shows that in very few was the organism concerned satisfactorily identified as the genuine malignant edema bacillus. Very often it has been simply assumed without more than a microscopical examination that bacilli found in spreading edematous conditions with or without gas have been those of malignant edema, and even where cultures and animal experiments have been employed the descriptions are frequently so meager as to leave the identity of the organism wholly in doubt. In France it is usually assumed without any discussion and even without any bacteriological examination that gangrène foudroyante is malignant edema (Pasteur's septicemia),³⁹ and the same ignorance of the present status of this subject is still sometimes encountered in England, Germany, and elsewhere. Nevertheless the investigations of the last seven years, beginning with those of E. Fraenkel and soon followed by observations of myself and collaborators, have demonstrated that by far the most common and important specific cause of gaseous phlegmons or emphysematous gangrene is *Bacillus aerogenes capsulatus*.

Whether the bacillus of malignant edema can produce an identical or similar anatomical and clinical affection in human beings I regard as an unsettled question. It is certainly remarkable in view of current doctrines in textbooks that neither E. Fraenkel nor I with our relatively large experience, nor indeed, so far as I am aware, anyone who has made himself thoroughly acquainted with *Bacillus aerogenes capsulatus*, has encountered an instance of emphysematous gangrene in man caused by the bacillus of malignant edema. The whole subject of human malignant edema is one which needs thorough revision and investigation by more exact bacteriological methods than have yet been applied to it.⁴⁰ I have already mentioned the chief points of difference between the bacillus of malignant edema and *Bacillus aerogenes capsulatus*.

There is a relatively small group of cases of gaseous phlegmon attributed by those reporting them,⁴¹ either to the colon-bacillus or the proteus bacillus. In most of these cases anaërobic culture-methods were not employed. No one has succeeded in producing experimentally gaseous phlegmon with either of these bacilli, and I think there is good reason to be skeptical concerning their capacity to produce this disease, unless perhaps *Bacillus coli* may do so in diabetics.

It is possible that some of those reporting the colon-bacillus as the cause of emphysematous gangrene may have confounded with it a facultative anaërobic bacillus which we have isolated from two cases of this disease, and which has been studied in my laboratory by Dr. Lanier. It resembles in anaërobic cultures very closely *Bacillus aerogenes capsulatus*, but it is capable of aërobic growth also, and then the rods are thinner and more like colon-bacilli. It has the power of producing gas abundantly in the blood and tissues of rabbits killed a few minutes after intravenous injection, a power not possessed by genuine colon-bacilli. I have already spoken of the importance of this test, which has been employed by none of the writers who have claimed to find colon-bacilli as the cause of gaseous phlegmons. This bacillus, when virulent, is capable of causing the same spreading and fatal emphysematous necrosis in

guineapigs and pigeons as is *Bacillus aerogenes capsulatus*.

I have been accustomed to speak of this bacillus, to which I have called attention in previous publications, as the aërobic variety of our gas-bacillus. I believe, however, that it is identical with Sanfelice's *Bacillus pseudo-œdematis maligni*⁴² with which he has inclined to identify Klein's "new bacillus of malignant edema."⁴³ Chavigny⁴⁴ has isolated apparently the same bacillus, which he likewise identifies with Sanfelice's *Bacillus pseudo-œdematis maligni* (not to be confounded with the pseudo-edema bacillus of Liborius), from a case of gaseous gangrene, and he also calls attention to the probability that others may have mistaken it for the colon-bacillus. While, therefore, unwilling upon existing evidence to accept the colon-bacillus as a demonstrated cause of gaseous gangrene (except perhaps in diabetics), I am of the opinion that an aërobic bacillus, probably identical with Sanfelice's *Bacillus pseudo-œdematis maligni*, is capable of producing this affection, but it is much less frequently concerned than *Bacillus aerogenes capsulatus*.

I have collected 46 cases of emphysematous gangrene, in all of which *Bacillus aerogenes capsulatus* was demonstrated, and, therefore, all reported or observed during the last seven years.⁴⁵ This is a far larger number of cases than has ever been brought together before.

Thirty-two are reported by American observers, and only 14 by foreign investigators. Of the former group of cases 16 were observed in Baltimore, most of the cultures having been studied in my laboratory; of the foreign group of cases all are reported from Germany, Austria, Italy, and France, 4 by E. Fraenkel, 1 (not absolutely certain) by Passow, 5 by Hitschmann and Lindenthal, and 3 by Muscatello, assisted by Gangitano, and 1 by Guillemot.⁴⁶

Cases of gaseous phlegmon in which *Bacillus aerogenes capsulatus* was not demonstrated are not included, although many of these presented the same clinical characters and doubtless in some cases at least the gas-bacillus was the active agent. This is true especially of the cases of gangrène toudroyante, usually without satisfactory bacteriological examination attributed by French writers to Pasteur's *vibron septique*. Gertler's⁴⁷ 8 cases of gaseous phlegmon cannot be utilized for our purposes at all, as they are without any satisfactory bacteriological reports.

A complete analysis of these 46 cases would afford material more than sufficient to occupy this entire address, so that I shall be able to present here only some of the more important points.

Thirty-five of the patients were males, 10 females, and of 1 the sex is not stated. The preponderance of males is to be explained by the fact that most of the cases were due to severe injuries. Robust workmen in the prime of life furnished the largest contingent of cases.

In 80% of the cases one of the extremities was the seat of the emphysematous gangrene, the lower being affected a little over twice as often as the upper extremities. In several instances the emphysema extended from the thigh to the abdominal wall, or from the arm to the subcutaneous tissues of the shoulder and chest. There were three examples of primary emphysematous phlegmon of the abdominal wall: of these one following removal of the appendix (bloodgood), one from an unrecognized strangulated Littre hernia (Martin), and one

affecting the deep tissues of a nephrectomy wound (Muscatello). In all of these the infection is believed to have started from the intestine. In one of Dunham's cases there was emphysematous gangrene (originating in a prostatic abscess opening in the buttock) of the scrotum, penis, and anterior abdominal and thoracic subcutaneous tissues. In 3 instances (Carroll 2; Dobbin 1, reported by Bloodgood) the breast and submammary tissues were the primary seat of the disease, all of these resulting from the infusion of salt-solution. In one case (Dunham) the gaseous phlegmon appeared at the angle of the lower jaw after incision of a foul submaxillary abscess. In one instance (Welch and Flexner) it started within the pelvis from traumatic rupture of the rectum and extended through the sciatic notch down the thigh.

Of especial interest are three examples of multiple or metastatic emphysematous gangrene; one of the forearm and opposite shoulder, another of the thigh and both shoulders, and still another of one shoulder and the buttocks. In the older literature are similar cases; thus Nélaton observed emphysema not only in the injured leg, but also in the opposite, uninjured extremity. In 1897, Leech⁴⁸ reported, without adequate bacteriologic examination, a case of emphysematous gangrene of the right leg following about three weeks after injury of the right thumb, which became inflamed, there being no evident local cause of the affection of the leg. These cases are to be explained by transportation of the bacilli through the lymphatic or blood-current from the primary focus of entrance.

In all but 5 of the 46 cases the emphysematous gangrene followed traumatism or a surgical operation. The injuries were as follows: Compound fractures, 18; bullet and gunshot wounds, 7; infusion of salt-solution, 3; hypodermic injections, 2; ligation of the femoral artery for aneurysm, 3; external urethrotomy, 2; traumatic rupture of the rectum, removal of the appendix, prostatic abscess following self-catheterization, operation for strangulated Littre's hernia, incision of a foul submaxillary abscess, and nephrectomy, each one. Of the 5 nontraumatic cases the gaseous gangrene followed erysipelas in 1, was consecutive to apparently spontaneous gangrene in 2, whether diabetic or not is not stated, and was without apparent explanation in 2 (Fraenkel's Case 2 and Passow.)

Compound fractures and next bullet and gunshot wounds occupy by far the most prominent place in this list, each of the other various causes being represented only by scattered cases. Those injuries in which there are much laceration and crushing of tissue, comminution of bone and grinding of dirt, bits of clothing or other foreign bodies into the wound, are the ones most likely to be followed by emphysematous gangrene. That, however, severe traumatism is not an essential factor is shown by the five cases (10.9% of the entire number) following hypodermic injections and infusion of normal salt-solution. These latter, however, were all of patients whose vital forces were greatly depressed, namely, by Asiatic cholera, typhoid fever, surgical shock, or postpartum hemorrhage. There is good reason to believe that the intact tissues of human beings in health possess marked resistance to the gas-bacillus.

In the great majority of cases it was evident that the gas-bacillus was introduced through the wounded skin from without. In three instances (removal of appendix, strangulated hernia, and traumatic rupture of the rectum) the infection undoubtedly came from the

intestine. This was also the probable source of infection in one of Muscatello's cases (gaseous phlegmon in the site of an extirpated kidney). With our present knowledge of the frequent, if not regular, presence of *Bacillus aerogenes capsulatus* in the intestine, there is nothing surprising in this mode of infection. In three of Dunham's cases the infection followed injury of the urethra, and here also the bacilli may have come primarily from the intestine. In one of his cases (gaseous phlegmon at angle of the jaw) it was suggested that the bacilli gained entrance through decayed teeth.

Bloodgood thinks it probable that in one of his cases the gas-bacilli were brought by the circulation to the seat of infection. In this case the femoral artery was ligated for traumatic arteriovenous aneurysm in the popliteal space. There was no primary infection of the wound, but gangrene of the foot and leg ensued and on incision gas-bubbles were found in the blood of the aneurysmal sac and the tissues. With what we know about the entrance of intestinal bacteria into the circulation, there is nothing improbable in Bloodgood's opinion. The clot in an aneurysm and tissues robbed of their nutrient supply would offer little or no resistance to the growth of bacilli which might reach them or their immediate neighborhood through the circulation, and the conditions would be anaerobic. It was indeed a case of aneurysm in which I first found the gas-bacillus, and here the clot was swarming with bacilli. It is interesting to note that three of the cases of emphysematous gangrene in my list followed ligation of the femoral or popliteal artery for aneurysm.

Pirogoff⁴⁹ distinguished clinically two groups of cases of traumatic emphysematous gangrene. He described under the name "primary mephitic gangrene" cases in which the emphysema appears within two days after the injury, the "local stupor" passing without inflammatory reaction into crepitating gangrene. Here the emphysematous necrosis spreads rapidly, the patient sinks into collapse, with an icteroid hue of the skin, small, thready pulse and cold sweats, and death occurs usually within a few days after the onset. This type of the disease corresponds to Maisonneuve's *gangrène foudroyante*. In the second group, designated by Pirogoff also as "acute gangrenous edema," there is reaction from the primary "local stupor" of the tissues, the emphysema is preceded and accompanied by local, edematous or purulent inflammation, is associated with febrile reaction, often appears later after the injury and spreads less rapidly, and presents in general a more varied anatomical and clinical picture than the first class of cases.

Hitschmann and Lindenthal consider that Pirogoff's first group corresponds especially to cases of pure or predominant infection with the gas-bacillus, and his second group to mixed infections. Erdmann is also of the opinion that in the unmixed infections the emphysematous necrosis spreads more rapidly and is more likely to terminate fatally. On the other hand, Muscatello and Gangitano, who also divide the cases into two groups—pure infections and mixed infections—hold that the mixed infections are characterized by the rapidly progressive form of emphysematous gangrene, while the pure infections, at least in their early stage, show little tendency to spread beyond the injured tissues. According to the last-named authors, the gas-bacillus is incapable of exerting any pathogenic action upon healthy tissues, but attacks only tissues already altered in their vitality by injury,

other pathogenic microorganisms, toxins, or other depressing factors.

The study of our cases has not enabled me to adopt either of the two conflicting opinions just stated. Of the collected 46 cases, 30 were mixed infections, 14 were pure, and in 2 there is no clear statement on this point. The most common associated bacteria were the pyogenic streptococci and staphylococci. Other forms found occasionally were *Bacillus coli*, proteus, pyocyaneus, tetanus, Sanfelice's *Bacillus pseudo-oleumatis maligni*, and uncultivable, often spore-bearing, bacilli. It seems probable that the bacillus of malignant edema, being a common inhabitant of the soil, must occasionally, like the tetanus-bacillus, be present, but it was not isolated from any of these cases. My experience is, that if reliance be not placed exclusively upon cultures, but careful microscopical examinations be also made, instances of unmixed infection with the gas-bacillus are rare. It is by no means always easy to determine whether associated bacteria are exerting pathogenic action or not. Pyogenic cocci may be present without producing pus or marked inflammatory reaction.

We have found rapidly progressive forms of emphysematous gangrene both with pure infections with the gas-bacillus and with mixed infections, and on the other hand we have observed with both types of infection cases in which the tendency to spread is much less marked. In all of the cases with much purulent inflammation mixed infection was present, but aside from this feature the division of the cases into pure and mixed infections does not, according to our experience, correspond to different, sharply marked, clinical features. Pirogoff's classification is doubtless of clinical value, but there is every gradation between the two groups.

I cannot agree with Muscatello and Gangitano, whose investigations of emphysematous gangrene are of great value, that the gas-bacillus is incapable of attacking healthy tissues. Virulent cultures, even in small doses, can produce rapidly spreading gaseous phlegmons when inoculated into the subcutaneous tissues of susceptible animals, such as guineapigs and pigeons. In human beings the emphysema may extend very rapidly into the healthy tissues, frequently outstripping in its advance the inflammatory edema. This may occur in pure as well as in mixed infections with the gas-bacillus. It is true, as urged by Muscatello and Gangitano, that toxins derived from the bacilli may prepare the tissues for the invasion and action of the advancing bacilli, but the same explanation has been put forward for the spread of other pathogenic bacteria in healthy tissues. In asserting that the gas-bacillus may attack healthy tissues, I would not be understood as minimizing the great importance of the various accessory causes of emphysematous gangrene which act by lowering the vitality of the tissues or the general resistance of the patient or as failing to recognize the marked resistance to infection by the gas-bacillus offered by the healthy tissues, a resistance to which I have previously called attention and which I shall have occasion further to emphasize.

Gas may appear in the tissues as early as eight hours after the injury. In a case of gaseous phlegmon following a bullet wound of the knee-joint, reported by Welch and Flexner, Dr. Bloodgood recognized gas in the joint⁶⁰ and surrounding tissues just twenty hours after the injury. In a case of Dr. Tiffany's, which we have reported, death from emphysematous gangrene,

due to pure infection with the gas-bacillus, occurred forty-eight hours after a fall causing a compound, comminuted fracture of the patella with grinding of the underclothing into the wound. There was no other injury of the body. Any one who has seen one of these rapidly fatal cases of spreading, traumatic, emphysematous gangrene will receive an impression which he will never forget.

The anatomical and clinical study of uncomplicated emphysematous gangrene demonstrates that the disease is not, as many formerly supposed, simply an intense variety of ordinary phlegmonous inflammation or cellulitis, but is a disease sui generis. It may be combined with phlegmonous inflammation, but then some other microorganism, usually the streptococcus, is associated with the gas-bacillus.

In typical uncomplicated cases the lesions consist in necrosis of all the tissues, the presence of gas in the interstices, infiltration with blood, evidences of the mechanical action of the gas, and exudation of a variable amount of bloody serum. The amount of gas varies much in different cases. There may be only a few bubbles or the tissues may everywhere be blown up with gas. The nuclei disappear by karyolysis. The notable thing in most cases is a nearly complete absence of leukocytes and of cellular reaction, although in a few instances, even of pure infection, I have found leukocytes in considerable number, and even purulent foci, but generally at a distance from the primary necrosis. As will be shown later, *Bacillus aerogenes capsulatus* in certain situations is capable of setting up purulent inflammation. In one of our cases, reported by Bloodgood, Dr. Cushing found gas-bacilli without gas in a small subcutaneous abscess of a stump two months after amputation of the thigh for emphysematous gangrene of the leg, the amputation having been followed by uninterrupted convalescence.

After death there may be rapid extension of the subcutaneous emphysema, and at autopsies made a few hours after death gas-bubbles may be found in the heart, vessels, liver, and other organs, but as to this occurrence there is no rule. As I have already explained, widespread distribution of gas in the blood and organs in early autopsies indicates entrance of the bacilli into the circulation during life.

As is to be expected from the etiology of many of the cases of emphysematous gangrene, emboli of fat and of bone-marrow cells are common in the pulmonary capillaries, but I do not know that in any case they contributed to the fatal result.

The prognosis of emphysematous gangrene is more favorable today than before the antiseptic period. The disease terminated fatally in 59% of the cases in my list. In the cases observed and treated at the Johns Hopkins Hospital—10 in number—the fatality was 50%, but of these one was a gaseous phlegmon of the pelvis extending to the thigh, resulting from traumatic rupture of the rectum; a second was a gaseous phlegmon of the abdominal wall following removal of the appendix and complicated with diffuse gangrenous peritonitis, and a third case terminated 25 days after disappearance of a gaseous phlegmon of the thigh (treated by incisions) from a late streptococcus infection, gas and the gas-bacillus having disappeared. Of the two remaining fatal cases in one—emphysematous gangrene following compound fracture of the thigh—amputation was refused by the patient until the fourth day when he was in a state of collapse and died 15

hours later, and in the other—compound fracture of the skull and both lower extremities—the patient died 30 hours after the accident, having never regained consciousness. When the disease is accessible to surgical treatment, is not complicated by other grave conditions, and is promptly recognized and treated, the prognosis, according to the experience of my surgical colleagues, Professor Halsted and Dr. Bloodgood, is not very unfavorable.

The clinical evidence seems to me to favor the view that, at least in most uncomplicated fatal cases, death is due to toxemia. Norris was unable to demonstrate the presence of strong toxins in artificial cultures of *Bacillus aerogenes capsulatus*, but, as is well known, the same difficulty is encountered with many other pathogenic bacteria which are believed to produce poisons in the human body. Muscatello is also of the opinion that the constitutional symptoms are attributable to toxemia.

The suggestion that death may be due to gaseous embolism is not new. Pirogoff and others of the older observers knew that gas-bubbles may be found within the heart and vessels very soon after the death of patients from emphysematous gangrene. In the discussion on Langenbeck's paper on traumatic infiltration before the Society of German Military Surgeons in 1870, Senator⁵¹ advocated the idea that death is caused by gas-embolism. While the possibility of this occurrence as the cause of death may be admitted, there is at present no proof of this opinion. Gas-bubbles are by no means always found in the blood and organs after death from emphysematous gangrene, and the clinical histories of those in whom they are found *post mortem* do not appear to differ from those where they are absent. In experimental gaseous phlegmons in guineapigs there is no evidence of the presence of gas-bubbles in the circulation during life.

In one of our cases (Mann) death resulted from tetanus, and Verneuil⁵² has reported three cases, which without bacteriological examination he calls malignant edema, where also tetanus intervened. There is nothing surprising in this association when one considers that the home of the tetanus-bacillus, like that of the gas-bacillus, is the soil. The period of incubation for tetanus is longer than for infection with the gas-bacillus, the former appearing rarely before the seventh day, and the latter usually within two or three days after the injury.

Prophylactic measures against emphysematous gangrene are sufficiently obvious from the etiological factors which have already been considered. It is important in wounds of the character most frequently followed by this complication to search microscopically and by culture for the gas-bacillus. The examination of cover-slips will usually suffice for a probable diagnosis. I have already cited instances in which this bacillus has been detected before the onset of emphysema and in which there is good reason to think prompt surgical treatment warded off severe infection. The possibility of infection from the intestinal canal, as well as from external sources, is to be borne in mind.

The cases were treated either by free incisions or by amputation or both. The results were better after amputation than after simple incisions. Of the cases of emphysematous gangrene affecting primarily the extremities, the recoveries numbered 68% after amputation, and 33½% after incision without amputation. Careful study of individual cases shows that amputation is by no means always necessary. Everything

depends upon early recognition of the nature of the infection. Dr. Bloodgood⁵³ from a relatively large experience says: "If the infection is recognized early, and the destruction of the soft parts and bone is not extensive, free incisions with immediate continuous bath-treatment should be tried. If the general symptoms of infection are not immediately relieved, amputation should be done. If, however, the infection is recognized late one should take no risk, but amputate at once. . . . An early diagnosis will probably save life, and from many observations an amputation may not always be necessary."

A similar position as to prognosis and treatment is taken by Muscatello and Gangitano in their valuable paper on gaseous gangrene, in which they also emphasize the value of abundant irrigations with disinfectant and oxidizing solutions. In the service of Dr. Halsted at the Johns Hopkins Hospital the continuous bath treatment has been found useful. Hirschmann and Lindenthal are certainly mistaken in their assertion that incisions are usually without favorable effect and that early amputations offer the only chance of recovery. As pointed out by Thorndike and others, recovery may follow amputation even when it is impossible to remove the whole of the diseased tissues.

UTERINE INFECTIONS.

Knowledge of *Bacillus aerogenes capsulatus* is of not less interest and importance to the obstetrician than to the surgeon. Infection of the puerperal uterus by this microorganism leads to a variety of morbid conditions, some comparatively mild, others of the utmost gravity.

The wide distribution of the gas-bacillus in the intestinal canal and the outer world renders as explicable the occasional presence of this bacillus in the female genital tract as that of the colon-bacillus in the same situation. Lindenthal⁵⁴ found the gas-bacillus in the vagina without the presence of gas or other pathogenic effects twice out of six puerperal cases examined. According to the observations of others, Lindenthal's experience would seem to be exceptional. As with so many other pathogenic bacteria, the mere presence of the organism upon exposed surfaces does not necessarily signify infection.

I shall consider the uterine infections by the gas-bacillus under the headings of emphysema of the fetus, puerperal endometritis, physometra, emphysema of the uterine wall, and puerperal gas-sepsis, although these conditions may be associated with each other.

Emphysema of the Fetus.—The occurrence of emphysema in the dead fetus in utero has been known for centuries,⁵⁵ but it was not until 1897, when Dobbin published his paper on "Puerperal Sepsis due to Infection with the *Bacillus Aerogenes Capsulatus*,"⁵⁶ that the cause of this condition was determined to be invasion by the gas-bacillus. In this case gas and the gas-bacillus were both recognized during the life of the patient in the fetus, the placenta, and the cavity of the uterus, and after death there was general gas-formation throughout the body.

Dr. Dobbin has kindly given me the notes of a second unpublished case observed by him. He was called to see a woman in difficult labor, upon whom repeated attempts at delivery of a dead fetus had been made. Upon examination, he recognized crepitation of the caput succedaneum while the fetus was still in utero. Upon delivery, the fetus was emphysematous, with foamy organs. The gas-bacillus was found in pure

culture in the fetus and mixed with other bacteria in the amniotic fluid. No gas was recognized in the uterus after delivery. The patient made a good recovery, without evidence of sepsis.

Menge and Krönig⁵⁷ have observed three instances of fetal invasion by the gas-bacillus, and have brought strong evidence that usually the invasion is through the mouth of the fetus, the bacilli being taken into the lungs or stomach by inspiring or swallowing amniotic fluid. In their cases the bacilli were not found in the part of the umbilical cord attached to the placenta; but in Dobbin's first case, this, as well as the placenta itself, was infected with the gas-bacillus. The amniotic fluid within the intact membranes, as is well known, is usually sterile, and only exceptionally becomes infected before rupture of the membranes, so that the infection of the fetus from this source is generally after this rupture. As shown by Menge and Krönig, all grades of invasion of the fetus by the gas-bacillus occur, so that there may be only a small amount of gas, and this limited to the lungs or the alimentary canal or both. The medico-legal importance of not mistaking for air this gas in the fetal lungs, produced by gas-bacilli, should be emphasized.

As is well known, fetal emphysema is usually unattended with danger to the mother. In two of the five cases due to *Bacillus aerogenes capsulatus* in my list the puerperium was even without rise of temperature, in two there was mild fever, but in Dobbin's first case there was rapidly fatal gas-sepsis.

Puerperal Endometritis.—Under the heading "gas-sepsis" will be considered cases of acute uterine infection with the gas-bacillus followed by invasion of the blood and organs by this organism. Here it may be mentioned that *Bacillus aerogenes capsulatus* may be present in the uterus, usually in association with other bacteria, in both mild and severe cases of puerperal endometritis without the recognition of gas in the fetus, or the uterine cavity, or wall. An example of such a case is an unpublished one in the service of Dr. J. Whitridge Williams, of which the notes have been furnished me by Dr. Dobbin. A woman with a rachitic pelvis, upon whom delivery by forceps had been attempted before admission to the Johns Hopkins Hospital, was there delivered by craniotomy. There was no gas in the fetus. Forty-eight hours later *Bacillus aerogenes capsulatus*, together with streptococci, was found in the uterine lochia. No gas was detected. The patient developed fever, but recovered.

In two cases, one reported by Dobbin⁵⁸ and the other by Blumer,⁵⁹ the gas-bacillus, although not identified with absolute certainty, was probably present in the puerperal uterus in association with the typhoid bacillus.

Physometra.—Distention of the uterine cavity with gas (physometra or tympany of the uterus) was present in Dobbin's first case, already cited, and is often associated with emphysema of the dead fetus, but may occur without the latter and even in the non-pregnant uterus. This curious condition was formerly ascribed to entrance of air or to ordinary putrefaction,⁶⁰ but it is now known to be the result of the activity of gas-producing bacilli.

Since the observations of Lindenthal,⁶¹ reported in 1898, it cannot be doubted that *Bacillus aerogenes capsulatus* is the chief cause of physometra. He found this bacillus in five cases during life and reproduced the condition experimentally in guineapigs. He is justly skeptical of the correctness of the previous reports

of Gebhard⁶² concerning the agency of the colon-bacillus in generating gas within the uterus. We know from Theobald Smith's investigations that the colon-bacillus can produce gas only from carbohydrates, whereas it is the most distinctive biological attribute of our gas-bacillus that it can produce gas from proteids. Until it has been shown that the amniotic fluid and uterine contents may under any conditions contain enough carbohydrate to explain the development of gas by the colon-bacillus, there is every reason to question the claims of this bacillus as a cause of tympany of the uterus.⁶³

My list of cases contains ten instances of physometra in which *Bacillus aerogenes capsulatus* was demonstrated. Although, as some of our cases show, this condition may be associated with invasion of the bacilli into the wall of the uterus and by acute gas-sepsis, these occurrences are exceptional and the prognosis is in general a favorable one. Most of the cases furnish a good illustration of the resistance of living human tissues to the action of the gas-bacillus. Doubtless in these cases the bacilli grow simply in the amniotic fluid after rupture of the membranes, and in the dead fetus, these offering no vital resistance, whereas we must suppose that the intact uterine wall offers ordinarily an effective resistance to the invasion and multiplication of the gas-bacillus. That occasionally the bacilli may find other dead material in the uterus, as in sloughing myomata and cancers, is evident from the histories of some cases of physometra.

Emphysema of the Uterine Wall.—Far graver in significance is septic emphysema of the uterine wall, of which Halban⁶⁴ has recently reported an interesting case, due to *Bacillus aerogenes capsulatus*. Graham, Steward and Baldwin and P. Ernst were the first to demonstrate this bacillus in this condition, their papers, to which reference has already been made, appearing simultaneously in August, 1893. Eleven instances of emphysema of the wall of the uterus, all puerperal, have been reported, of which 5 were recognized during life. In all but Halban's case there was also physometra, and this would seem to be a necessary accompaniment, unless the cervical canal is open, so as to permit the escape of the gas from the uterine cavity. All of the cases were fatal, and in most gas was found at autopsy in the blood and internal organs.

Subperitoneal emphysema has been observed after rupture of the uterus, Dischler⁶⁵ having collected reports of 14 cases. In most instances this has been attributed to entrance of air, but I think that it is safe to predict that the gas-bacillus will be found in similar cases in the future, if proper methods for its detection are employed. I know, however, of no instance of this condition in which it has been looked for.

Puerperal Gas-Sepsis.—I have adopted from Halban the term "gas-sepsis" as a convenient one—although, perhaps, open to criticism—to designate the important group of fatal puerperal cases in which gas-bubbles are found at early autopsies in the heart and vessels, and often also in the organs and tissues, under conditions where we must suppose that gas-bacilli, and possibly gas, have passed from the uterus into the circulation during life.⁶⁶ Here, in my opinion, belong most of the cases which have been reported as deaths due to the entrance of air into the uterine veins. This opinion, which I expressed in my first communications on the gas-bacillus, in 1891 and 1892, received prompt confirmation in the papers of Graham, Steward and Baldwin,

and of P. Ernst, in August, 1893, and has since been strengthened by other similar observations. Cases described by Wendeler⁶⁷ as sepsis acutissima belong also in the same category.

My list includes 12 puerperal cases in which gas-bubbles and the gas-bacillus were found at autopsy in the blood and organs; but in only 6 of these does it seem to me conclusive or extremely probable that the infection occurred during life.⁶⁸

The most remarkable of these cases is that reported by Graham, Steward and Baldwin of a woman, upon whom abortion had been recently produced, who during the four hours immediately preceding death became emphysematous over nearly the whole body. At the autopsy gas and gas bacilli were found everywhere throughout the body. In Dalton and Bremer's⁶⁹ case, also one of criminal abortion, an emphysematous swelling of the arm and pectoral region was likewise recognized during life. These cases are of importance as demonstrating the invasion of the body by the gas-bacillus from the uterus while the blood is still circulating. In Halban's and Dobbin's cases gas was recognized also during life within the wall or cavity of the uterus.

In the majority of cases of puerperal gas-sepsis there has been some operative interference preceding infection, such as criminal abortion, forced delivery for placenta prævia or other causes, or the manipulations of an unskilled midwife. The fulminating character of the infection, death being sometimes very sudden, is a noteworthy feature of many of the cases.

In a case of attempted criminal abortion reported by Perkins⁷⁰ the patient, according to the statement of the practitioner in whose office death occurred, died suddenly, and at the autopsy 12 hours later in cold weather, gas was found in the vena cava, heart, and other vessels, with evidences of injury to the pregnant uterus. The case was reported by Perkins as one of death from air-embolism, and certainly with as much and even more plausibility than most cases thus reported. After the publication, Dr. Perkins, upon the request of Dr. Dobbin, was so good as to send the uterus, well preserved in alcohol, to my laboratory where Dr. Dobbin demonstrated in the uterine vessels and tissue bacilli morphologically and in staining reaction identical with *Bacillus aerogenes capsulatus*.⁷¹

I would not be understood to deny the possibility of the occurrence of fatal air-embolism from the uterus. A very few of the reported cases are difficult to interpret upon any other supposition, but I do claim that the foundations of this doctrine have been seriously shaken by our discovery and investigations of the gas-bacillus, and that no case, however plausible, can be considered as positively proved without a satisfactory bacteriological examination. The limitation of gas to the right heart and adjacent vessels may occur from invasion by the gas-bacillus and is not, as often represented, peculiar to air embolism. Did we not know how long it takes new knowledge, especially that originating in this country, to penetrate throughout the medical world, it would be amazing that cases should still continue to be reported, as they are,⁷² of deaths ascribed to air embolism without any bacteriological examination or even any reference to the possibility of any other explanation. I am not aware that in any instance of alleged air-embolism, a bacteriological examination has been made, which would exclude the presence of gas-forming bacteria.

Whether, as suggested by Staude, in any of the cases with gas within the uterine cavity, death is attributable to gaseous embolism, is, I think, an open question. It is possible, although I know of no proof of it, that in some of the cases of sudden death during or immediately after some manipulation or operation on the pregnant uterus and attributed to air-embolism, gas, generated by bacteria, may have existed under pressure within the uterine cavity and have entered wounded veins in sufficient amount and so suddenly as to have caused death.

To what extent the free gas found in the blood-vessels, heart, and internal organs, even very soon after death from what has been described as puerperal gas-sepsis, is there during life, is a question difficult to answer. I have already considered this subject, and in this connection shall again emphasize the importance of caution in interpreting the presence of gas in these situations as a vital phenomenon, although there is evidence that it may be such.

INFECTIONS OF THE URINARY TRACT.

There is evidence that the urinary tract may not only be a portal of entrance for the gas-bacillus into the circulation or adjacent tissues, but also be itself the seat of infection by this organism. Unfortunately for the decisive interpretation of many of these cases, *Bacillus aerogenes capsulatus* has, so far as I am aware, hitherto been found in the urinary tract only after death, although in some instances so soon thereafter and under such conditions that its presence during life cannot be doubted.

I have already called attention to instances of emphysematous gangrene following external urethrotomy and other operations on the urinary passages.

Among the cases of general invasion of the blood and organs (foamy organs) by the gas-bacillus observed by myself and others are several in which the portal of entry was the urethra, bladder, or other part of the urinary tract.⁷³ In a case of urethral stricture with cystitis, for which perineal section had been done, reported by Welch and Flexner, gas-bacilli were found *three-quarters of an hour after death* in large numbers in the bladder, ureters, and renal pelvis, and a few gas-bubbles and gas-bacillus were already present in the blood of the right ventricle. In Howard's case of meningitis caused by the gas-bacillus, to be cited subsequently, he considers that the portal of entry was the urinary tract.

Gas generated by *Bacillus aerogenes capsulatus* has been found in the urinary passages in six cases which have come to my notice.⁷⁴ The gas may be either free in the cavity of the bladder, ureters, or renal pelvis, or contained within submucous blebs, or in both situations.

Welch and Flexner⁷⁵ have reported an instance of pneumaturia in a diabetic man in whom, six hours after death, without trace of cadaveric decomposition, the urinary bladder was found filled with frothy urine containing *Bacillus aerogenes capsulatus* in pure culture. This case indicates that the colon-bacillus and *Bacillus lactis aerogenes* are not the sole causes of pneumaturia in diabetics. Dr. Flexner has given me the notes of a second case of pneumaturia upon which he made the autopsy at the University Hospital, Philadelphia. This was of a patient with chronic cardiac disease who had been catheterized 28 hours before admission and who died 30 hours after admis-

sion. At the autopsy, made one hour and a half after death, about 60 cc. of frothy urine were found in the bladder from which *Bacillus aerogenes capsulatus*, together with *Staphylococcus aureus* and *Streptococcus pyogenes* (no colon-bacilli), was cultivated. Neither gas nor gas-bacilli were found elsewhere in the body. The mucous membrane of the bladder was edematous. There can be little doubt that in this case the gas-bacillus was introduced by the catheter into the bladder.

In one of Welch and Flexner's cases (Case 18) of hypertrophied prostate with pyoureter and pyonephrosis the renal pelvis and ureters were found at autopsy distended with gas and containing pus mixed with bubbles of gas. Small gas-cysts were present in the mucous membrane of the renal pelvis. Neither gas nor gas-bacilli were present outside of the urinary organs. In this case cocci and colon-bacilli were associated with the gas-bacillus.

In a case of Dr. Kelly's, of which the full records have been given me by Dr. Miller,¹⁶ there was pneumaturia demonstrated by cystoscopic examination and ureteral catheterization to come exclusively from the inflamed left renal pelvis and ureter. Among cocci and other bacteria were found on cover-slips bacilli morphologically resembling *Bacillus aerogenes capsulatus*, but unfortunately no anaërobic cultures were made. None of the bacteria which grew aerobically produced gas in lactose agar. This case is interesting as demonstrating that the gas may come exclusively from one renal pelvis and ureter, but the microorganism producing the gas was not satisfactorily demonstrated. It seems certain that it was an anaërobic organism, and from the microscopical appearances may have been the gas-bacillus.

The subject of submucous gas-cysts will be considered subsequently, but here it may be mentioned that besides the gas-cysts in the renal pelvis noted by Welch and Flexner in the case already cited, Goebel found gas-blebs, containing in pure culture *Bacillus aerogenes capsulatus*, beneath the mucous membrane of the urinary bladder, without gas elsewhere in the body, and Dunham has reported a similar condition of the bladder in a case of emphysematous gangrene with general invasion of the blood and organs by the gas-bacillus.

Bacteria have been found in emphysema of the bladder (cystitis emphysematosa) also by Eisenlohr,¹⁷ Camargo,¹⁸ and Kedrowsky,¹⁹ but it is impossible from the authors' descriptions to identify their bacteria. Kedrowsky considers the bacillus isolated by him as allied to *Bacillus aerogenes capsulatus*, but less sensitive to oxygen. Perhaps it was Sanfelice's *Bacillus pseudocædematis maligni*, to which I have already referred, but Kedrowsky's description of his cultures hardly inspires confidence in their purity.

Welch and Flexner, and Howard have reported finding the gas-bacillus, in association with other bacteria, in inflammatory lesions of the bladder, renal pelvis and kidneys, without the detection of gas. Howard considers that in one of his cases the bacillus was concerned in the etiology of suppurative lesions of the kidneys, but in this case the colon-bacillus and *Streptococcus pyogenes* were also present.

INFECTIONS DERIVED FROM THE GASTRO-INTESTINAL CANAL.

Mention has already been made of the frequent, if not constant, presence of *Bacillus aerogenes capsulatus* in the intestinal canal, of gaseous phlegmons originat-

ing from this source, and of the readiness with which intestinal bacteria may gain access to the genitourinary tract.

The intestine is by far the most common source of the gas-bacilli found together with gas-bubbles in the blood and organs at autopsies. This invasion may occur either with or without definite intestinal lesions, and is probably in the majority of cases an agonal or postmortem event. The mode of distribution and spread of the bacilli in these cases has been well described by Howard,²⁰ whose experience has been exceptionally large with this class of affections. Especially demonstrative of invasion of gas-bacilli from the intestine, usually postmortem, is the occurrence of gas-bubbles limited to the neighborhood of the intestine, as in the intestinal wall, within the portal or mesenteric veins, or lymphatics, in the subperitoneal tissues, mesentery and omenta, around the pancreas, in the mesenteric glands, and especially in the loose tissue near the gallbladder and in the porta of the liver, without gas in more remote situations. I have seen examples of each of these occurrences in very early autopsies without ordinary cadaveric decomposition.

Local Gastrointestinal Lesions.—Interstitial emphysema of the gastro-intestinal wall will be considered subsequently.

Howard has described several cases with larger or smaller areas of superficial necrosis of the mucous membrane of the stomach and intestine, in which gas-bacilli were present in large numbers. These areas, which may occur either with or without gas-cysts, are found most frequently beneath the folds of the valvule conniventes and are characterized by absence of nuclear staining and disintegration of the cells and tissue, usually without marked inflammatory reaction.

Bacillus aerogenes capsulatus may undoubtedly be a cause of meteorism. Instances of this are reported by Welch and Flexner and by Howard.

Pneumo-peritonitis with and without Perforation.—My records include 13 cases of diffuse peritonitis in the exudate of which *Bacillus aerogenes capsulatus* was found. Eleven of these were in autopsies made either by Dr. Flexner or myself, 7 having already been published by us in 1896. The remaining 2 cases (both being perforations of gastric ulcers) have been reported by Page,²¹ and by Pratt and Fulton.²² It was the observation of these cases which first called my attention to the frequent presence of the gas-bacillus in the intestine.

Ten of the cases were perforative and 3 were non-perforative. Of the former, 4 were the result of perforation of typhoid ulcers,²³ 4 of gastric ulcers, 1 of strangulated gangrenous intestine, and 1 of a cancerous ulcer of the duodenum. In the last case (autopsy 14 hours after death) the exudate was sero-fibrinous and the gas-bacillus was found in pure culture²⁴ and abundantly in the peritoneal cavity and was absent from other organs and the blood. In the other perforative cases the gas-bacillus was mixed with other bacteria, although in some instances it predominated. In all of the cases the abdomen was greatly distended with gas and usually there was great tympanites.

I attach especial importance to the case fully reported by Welch and Flexner,²⁵ in which we brought conclusive evidence of the occurrence of pneumoperitonitis without perforation, the first of the kind on record in which similar proof was obtained. Since our publication a similar case has been observed by Dr. Flexner in Manila, who has kindly furnished me the notes. At the

autopsy, 12 hours after death, there was found hemorrhagic infarction of the lower part of the ileum and adjacent part of the large intestine, caused by the passage of this part of the intestine through a hole in the mesentery. The peritoneal cavity was greatly distended with gas which burnt with a pale, blue flame. There was a large amount of frothy, bloody serum in the peritoneal cavity together with a fibrinous exudate. The most careful examination showed no perforation. *Bacillus aerogenes capsulatus* was obtained in pure culture and abundantly from the peritoneal fluid. Gas was absent from the blood and other organs.

We have found the gas-bacillus, mixed with other bacteria, twice in circumscribed, gas-containing, intraperitoneal abscesses resulting from perforation of the appendix vermiformis.

Hepatic and Biliary Infections.—The development of gas in the liver is so striking a phenomenon in most autopsies where the gas-bacillus and free gas are found in the blood and organs that P. Ernst used the term "Schaumleber" for the title of his article on the gas-bacillus, published a year after the paper by Welch and Nuttall in which we first directed attention to the subject of foamy organs and the gas-bacillus.⁸⁶ I have already considered the general subject of gas-bubbles in the blood and organs, and wish here to call attention especially to infections of the gallbladder and biliary passages by *Bacillus aerogenes capsulatus*.

In cases of foamy liver gas may be found in the bile-ducts and gallbladder, but my experience is that, when the gas-bacilli reach the liver through the bloodvessels, the appearance of gas in these situations is a rather late occurrence and met chiefly in advanced cases. In contrast to these cases are the observations of gas in the biliary passages, associated sometimes with definite lesions of the bile-ducts and liver, where the evidence is that the gas-bacilli entered from the intestine directly into the passages. Two such cases have been reported by Howard⁸⁷ and I have observed two cases.

Pratt and Fulton⁸⁸ report a remarkable case of cancer of the common bile-duct and pancreas in which cholecystotomy was performed, the opening in the gallbladder being stitched to the abdominal walls. At the autopsy the liver was found studded with minute abscesses with greenish translucent walls. In cover-slips, sections and cultures *Bacillus aerogenes capsulatus* was found in pure culture in these small biliary abscesses, but there was no gas in the abscesses, the liver, blood, or other organs. A somewhat similar case, in which cholecystenterostomy for gallstones had been performed, was previously reported by Nicholls⁸⁹ from Adami's laboratory. Here also multiple miliary abscesses containing the gas-bacillus were found in the liver, but in this case gas was present in the liver, as well as in the blood and other organs, the autopsy being six hours after death. Larkin⁹⁰ has likewise reported a case of hemorrhagic pancreatitis with fat necroses and small, multiple hepatic abscesses with gas-holes in the liver, from which *Bacillus aerogenes capsulatus* was isolated. The autopsy was eight hours after death.

Hintze⁹¹ has recorded a postmortem observation of gas in the inflamed bile-ducts with cholelithiasis. He cultivated only the colon-bacillus, but it does not appear that he made anaerobic cultures.

From the foregoing cases it is to be inferred that the gas-bacillus may invade the bile-ducts and gallbladder from the intestine, and sometimes during life, and that it may not only produce gas but also necroses and pur-

ulent inflammation. The presence of gallstones, cancer of the bile-ducts and operations on the gallbladder appear to favor this mode of infection.

Rist⁹² found the gas-bacillus (*Bacillus perfringens*) without gas or other lesion attributed to it in an extirpated gallbladder containing a calculus and clear viscid fluid.

INTERSTITIAL EMPHYSEMA OF THE GASTROINTESTINAL, GENITOURINARY AND BILIARY TRACTS.

One of the most interesting lesions produced by *Bacillus aerogenes capsulatus* is the formation of submucous or subserous gas-cysts or blebs, of which the earliest examples attributed to this organism were reported by P. Ernst, Goebel, and Welch and Flexner. They are sufficiently common to have been observed by nearly all investigators who have had much experience with the gas-bacillus in human beings. My list of cases includes 25 instances of this condition, of which 5 were of the stomach, 11 of the intestine (far oftener of the small than the large intestine), 5 of the gallbladder and bile-ducts, 3 of the urinary bladder, 1 of the renal pelvis, and 1 of the vagina. The majority of the cases were observed by Flexner, Howard, and myself, and in all the gas-bacillus was demonstrated. The case of emphysema of the vagina was reported by Lindenthal.⁹³

These gas-cysts vary in size from microscopic dimensions to large blebs. They are most common in the submucous coat, but may be present in the mucous membrane, the muscular coat or beneath the serous covering, in fact in any part of the membranous wall. They may be few or in enormous numbers, in groups or scattered. In one of our cases the whole small intestine from the duodenum to the ileocecal valve was studded with small gas-cysts. Gas-cysts of the same general character may be found in the mesentery and omenta.

These gas-cysts are in their inception simply such gas-holes as we are already familiar with in the liver and other organs in cases of local or general invasion with the gas-bacillus. They indicate a foamy or emphysematous condition of the walls of the stomach, intestine, gallbladder, bile-ducts, urinary bladder, and vagina, due to the invasion into these parts of the gas-bacillus.

The condition of the walls of the blebs and of the surrounding tissues varies. Some of the cavities are round and their walls smooth, others are irregular in shape and have ragged walls. They may correspond to dilated lymphatics, but more frequently they do not represent dilation of any preformed channels. There may be communication between adjacent cavities, but oftener the cysts are distinct from each other. The tissue in the immediate neighborhood of the cavities may present no alteration not explicable by the mechanical pressure of the gas, or it may show necrosis in varying degree and extent. Inflammatory changes or cellular reaction which could be reasonably referred to the presence of the cysts or of the gas-bacilli causing them were not noted. Sometimes a little coagulated, homogeneous or granular material is present in sections of the cysts in hardened tissues, as indeed may often be found in gas-holes in the organs.

In sections stained by Gram there is usually no difficulty in demonstrating the relation of the gas-bacilli to the cysts. The bacilli may be in masses in the walls of the cysts, but sometimes they are not more numerous there than in the tissue at a distance from the gas-blebs,

and occasionally it requires some searching to find them. By anaërobic methods the gas-bacillus can be cultivated from the cysts or the adjacent tissue.

All of the instances of submucous and subserous gas-cysts in my list were observed *post mortem*. In the larger number of cases gas bacilli and gas-bubbles were more or less widely distributed in the blood and organs, but without evidences of ordinary postmortem decomposition. There are, however, several cases in which these gas-cysts in various situations were the sole manifestation of the presence of the gas-bacillus in the body. Howard has shown that if careful, systematic search is made for areas of necrosis and minute gas-cysts due to *Bacillus aerogenes capsulatus* in the stomach and intestine, these lesions can be found much more frequently than has been supposed.

It is with our present information a difficult matter to say in how many of these cases the emphysematous state existed before death. It is certain that, at least in the great majority of cases in my list, the emphysema was not the result of ordinary postmortem decomposition. In a large number of the cases the autopsy was made within a few hours after death. Howard in one of his cases of gas-cysts, limited to the intestine, made the autopsy one hour after death. I have already emphasized the importance of great caution in interpreting as vital processes the various gaseous conditions of parts and organs not open to inspection during life, even when autopsies are made soon after death and there is entire absence of putrefaction, and I can only repeat this caution here. Mere absence of nuclear staining around gas-holes, I do not regard as proof of their origin during life.

It would lead altogether too far to enter here into a discussion of the general subject of submucous gas-cysts concerning which there is a large literature, the principal references to which will be found in the articles by Eisenlohr,⁹⁴ Camargo,⁹⁵ Winands,⁹⁶ Dupraz,⁹⁷ and Lindenthal.⁹⁸ It would appear from a study of the records of the subject that anatomically different conditions have been described under the designation "gas-cysts" (cystides aeriferæ). Some have been apparently of long standing and show chronic inflammatory changes in their walls and surrounding tissues. The most voluminous literature relates to the gas-cysts of the vagina (kolpohyperplasia cystica of Winckel, emphysema vaginae of Eppinger).

At present we have no warrant to identify the more chronic gas-cysts with thickened walls with the acute emphysematous condition which I have described as referable to *Bacillus aerogenes capsulatus*. Nevertheless the former are probably of bacterial origin also, although I am unable to accept the bacteriological findings of Eisenlohr, Camargo and Dupraz as at all convincing, for they made no use of anaërobic methods of cultivation. It is quite possible that *Bacillus aerogenes capsulatus* is concerned also in the etiology of the gas-cysts of long standing; certainly it is important to apply hereafter anaërobic cultural methods to their study. Lindenthal has no hesitation in identifying the emphysema of the vagina observed by him *post mortem* and from which in a single case he cultivated what he chooses to call *Bacillus emphysematis vaginae* (in reality our *Bacillus aerogenes capsulatus*) with Winckel's kolpohyperplasia cystica, but, while he may be correct, further observations are needed before this anatomical and etiological identification can be accepted.

The only instance in which gas-cysts of the human intestine have been recognized during the life of the patient is reported by Hahn,⁹⁹ who found them in large number upon opening the abdomen. It is to be regretted that no thorough bacteriological examination of this case was made.

In my original communication on the gas bacillus I ventured the surmise that the bacillus found by E. Fraenkel¹⁰⁰ in hardened sections from a case of gastritis emphysematosa might be identical with *Bacillus aerogenes capsulatus*, and this suspicion has gained in probability by Goebel's statements based upon an examination of the sections, his work having been done under Fraenkel's supervision.

Notwithstanding an effort at compression, so much space has been occupied in the presentation of the foregoing subdivisions of our subject, which in less than a decade has grown to considerable magnitude, that I shall only summarize very briefly a few remaining topics, although all deserve fuller treatment.

Pulmonary and Pleural Infections.—To the two instances of invasion of the lungs by the gas-bacillus, reported by Welch and Flexner, I can add the cultivation of this organism from a gangrenous lung by Dr. Flexner in my laboratory. It has been found also by Rist¹⁰¹ and Guillemot¹⁰² in pulmonary gangrene.

Of much importance is Levy's¹⁰³ demonstration of *Bacillus aerogenes capsulatus* as a cause of pneumothorax without perforation. This case and those of pneumoperitonitis without perforation to which I have already referred have settled affirmatively the long-standing controversy concerning the possibility of the generation of gas within closed serous sacs during life.

Nicholls¹⁰⁴ has reported an instance of pneumothorax and pneumopericardium without perforation in which the gas-bacillus was probably present. Rendu and Rist¹⁰⁵ also isolated the gas-bacillus (*Bacillus perfringens*) in a case of putrid pleurisy with gas. May and Gebhart¹⁰⁶ and Finley¹⁰⁷ attribute their two cases of pneumothorax without perforation to the colon-bacillus, but in neither were anaërobic cultures made. It is important in all gaseous affections to search for anaerobes.

Gas-Bacillus in the Blood During Life.—Extremely interesting is the demonstration by Gwyn,¹⁰⁸ both by cover-slip specimens and by cultures, on repeated examinations, of *Bacillus aerogenes capsulatus* during life in the blood of a patient, in the Johns Hopkins Hospital, with chorea insaniens and acute endocarditis. I had the opportunity of examining his cultures, which were entirely typical. The patient died, but unfortunately no autopsy could be obtained. There was no evidence during life of free gas in the blood or tissues. The case is of importance as demonstrating that gas-bacilli may be in the circulating blood for days in sufficient number to be demonstrable, both microscopically and culturally, without evidence of free gas. I have already expressed my suspicion that Achalmé's anaërobic bacillus, which has likewise been cultivated from the blood, as well as from the tissues, of several cases of acute articular rheumatism, is identical with *Bacillus aerogenes capsulatus*.

Presence of the Gas-Bacillus without Gas.—In this connection I may say that the gas-bacillus may be present and even multiplying within the human body without the production of gas. Certain organs—above all, the liver—offer much more favorable pabulum for the generation of gas than do others, but even in the liver

the bacilli may be present without gas. I have found gas-bacilli in small clumps within the spleen and kidney, surrounded by areas of necrosis, without recognizable gas. I have already cited the demonstrations by Cushing and by Pratt and Fulton of the gas-bacillus in small abscesses without gas, the observation of the latter being particularly complete and satisfactory. Rist¹⁰⁹ has cultivated the gas-bacillus (*Bacillus perfringens*) from cases of fetid otorrhea and of mastoid abscess. He does not mention the presence of gas in these cases, nor in the case of the gallbladder already cited. Dr. Harris, in my laboratory, isolated the gas-bacillus in pure culture from an abscess containing blood and pus in the neck of a dog, following an operation on the jugular vein. There was no gas in the abscess. Aërobic cultures were entirely negative. These observations, however, are not the only ones demonstrating that the gas-bacillus may, under certain circumstances and in certain situations, manifest pyogenic capacity.

Meningitis. Pyogenic Capacity of Gas-Bacillus.—Howard,¹¹⁰ in April, 1899, reported a case of acute fibrino-purulent meningitis, following operation for urethro-perineal fistula. *Bacillus aerogenes capsulatus* was found in pure culture in the meningeal exudate. Likewise Hirschmann and Lindenthal¹¹¹ have recorded another convincing example of acute cerebral meningitis following fracture of the occipital bone, in which the gas-bacillus was found unmixed with other bacteria. These authors call attention to the pyogenic power of the gas-bacillus when it attacks the meninges, but, as already shown, the same power may be manifested elsewhere.

Cavities in the Brain.—Finally I would call attention to Reuling and Herring's¹¹² and Howard's studies of cavities in the brain produced by *Bacillus aerogenes capsulatus* and to the light which their observations shed upon certain obscure examples of cerebral cavities previously reported.

In this excursion into pneumatopathology I have invited you to the survey of fields comparatively new and little trodden. I can only hope that our journey has not been without some interest and some profit to you. To me the opportunity to present before such a body as the Massachusetts Medical Society the results of these investigations is one which I highly appreciate.

I desire in closing to pay my tribute of respect and to call to your grateful remembrance the founder of this lectureship, Dr. George Cheyne Shattuck. That the subject of this address would not have been without interest to him may be inferred from the title of his first Boylston Prize dissertation on the theme propounded in 1806 and entitled "The difference between mortification produced by an external cause and that which is produced by a constitutional defect, the diagnostics and proper mode of treatment of each."¹¹³ By his noble character, professional services and liberality Dr. Shattuck deserved well of the medical profession of his city and State, and indeed of the whole country, and his memory is worthily perpetuated, not only by the foundation of this lectureship, but also by the endowment of the chair of morbid anatomy in the Harvard Medical School.

REFERENCES AND NOTES.

¹ Levy's description in 1891 (*Deutsche Zeitschr. f. Chirurg.*, xxxii) of "kleine, feine" bacilli, cultivated from a gaseous abscess and growing in long threads and chains only at body-temperature and cultivable only in the first generation, without animal experiments, cannot be accepted as an identification of *Bacillus aerogenes capsulatus*, or indeed be readily reconciled with its characters.

- ¹¹ *Stud. v. H. Bier* in 1899 (*Centralbl. f. Bakt.*, xxv, p. 513 et seq.) in an elaborate study of pathogenic anaerobes is entirely ignorant of our work and that of other American investigators on *Bacillus aerogenes capsulatus*. The information of Hirschmann and Lindenthal (*Sitzungsh. d. K. Akad. d. W., Math.-Naturw. Cl., Wien*, 1899) on the American work is secondhand and both incomplete and inaccurate, in these respects being in unfavorable contrast to that of Muscatello and Gangitano (*Riforma Med.*, 1900, ii, p. 508, et seq.) writing also on the subject of emphysematous gangrene. Knowledge of *Bacillus aerogenes capsulatus*, under the name "*Bacillus perfringens*," has begun to appear in France in the last two years, but without any evidence of acquaintance with the American publications. Even allowing for the great difficulties in keeping pace with the literature of any subject in medicine, a decade would certainly seem sufficient for the light to penetrate even into dark places.
- ¹² Migula, who, with considerable success, has attempted to reform bacteriological nomenclature, has given the binomial names "*Bacterium Welchii*" to *Bacillus aerogenes capsulatus* and "*Bacterium emphysematosum*" to *Bacillus phlegmonis emphysematosus* (*System der Bakterien*, ii, pp. 392 and 383, Jena, 1900). He is, however, in error in describing this organism under two different names, as his *Bacterium Welchii* and *Bacterium emphysematosum* are identical.
- ¹³ As regards these characters, it will suffice here to say that the microorganism is a rather coarse, non-motile, anaerobic bacillus, staining by Gram, growing on all of the ordinary culture media under anaerobic conditions, best at body temperature, but also at room temperature, forming spores incessantly according to the race and the culture-medium, and capable of forming gas not only by fermentation of sugars but also from proteids. The full description of the characters may be found in Welch and Nuttall's paper. The gas, according to Dunham's analyses, is composed approximately of 64% hydrogen, 28% carbon dioxide, and 8% of a residual gas believed to be mainly nitrogen. It has no foul odor.

- ³⁹ An exception is Guilleminot (*Compt. rend. Soc. de biol.*, 1898, 10, S., v, p. 1017), who has found *B. aerog. caps.* in a case of gaseous gangrene and who controverts the prevalent belief of authors who attribute this disease exclusively to Pasteur's vibrio.
- ⁴⁰ In the case reported recently by Brabec (*Wiener klin. Rundschau*, 1900, xiv, pp. 145 and 167) the identification of the malignant edema-bacillus seems satisfactory. Here there was extensive bloody edema without gas, so that the case was not one of emphysematous gangrene. On the other hand, the latest writers on the subject, Hünig and Silberschmidt (*Correspondenzbl. f. Schweizer Aerzte*, 1900, xxx, p. 351), bring no proof of any consequence that they were dealing, as they supposed, with the malignant edema-bacillus in two cases of gangrene foudroyante.

- ⁴³ *Centralbl. f. Bakt.*, 1891, x, p. 186.
- ⁴⁴ *Ann. d'Inst. Pasteur*, 1897, xi, p. 860.
- ⁴⁵ This list includes 16 cases observed in Baltimore, mostly at the Johns Hopkins Hospital, of which 2 are unpublished, and the remaining 14 have been published by Mayn (1), *Ann. Surg.*, 1894, xix, p. 187; Welch and Flexner (6), *Jour. Exp. Med.*, 1896, i, p. 5; Martle (1), *University Bulletin*, 1896, i, No. 3; and Bloodgood (6), *Progressive Medicine*, 1899, iv, December, p. 158. The notes of an additional unpublished case observed in Manila have been given me by Dr. Flexner. There are also 3 unpublished cases, for the records of which I am indebted to Dr. Carroll, of Washington.
- The references to the remaining 25 cases are as follows: E. Fraenkel (1), Ueber Gasphlegmonen, Hamburg u. Leipzig, 1893; Passow (1), *Charité-Annalen*, 1895, xx, p. 276; Dunham (5), *Bulletin of Johns Hopkins Hospital*, 1897, viii, p. 68; Ferguson (1), *Trans. Indiana Med. Soc.*, 1897, p. 339; Erdmann (1), *Med. Record*, February 5, 1898, p. 205; Le Boutillier (1), *Med. Record*, March 5, 1898, p. 353; Love and Cary (1), *Med. Record*, April 8, 1899; Norris (1), *Amer. Jour. Med. Sc.*, 1899, cxvii, p. 195; Hirschmann and Lindenthal (5), *Sitzungsh. d. k. Akad. d. Wiss., Math.-Naturw. Cl., Wien*, 1899, cxviii, Heft iii, Abth. iii, p. 67; Thorndike (2), *Boston Med. and Surg. Jour.*, June 7, 1900, p. 592; Muscatello with Gangitano (3), *Riforma med.*, 1900, ii, pp. 508, 519 and 530; Guilleminot (1), *Compt. rend. Soc. de biol.*, 1898, 10, S., v, p. 1017. A few other cases in which the gas-bacillus was found are not reported with sufficient detail to be available for analysis. It is safe to say that *B. aerog. caps.* has now been found in over 50 cases of gaseous gangrene.

⁴⁵ Soupazilt and Guilleminot (*Bull. et mém. Soc. mtd. d. hóp. de Paris*, 1900, 3.S., xlvii, p. 216) have reported 2 gaseous abscesses following hypodermic injections of salt-solution, and a third which they regard as metastatic, all due to the gas-bacillus (*B. perfringens*). These cases came to my notice too late to be included in my statistics.

THE EARLY RECOGNITION OF ECTOPIC PREGNANCY.

By DEWITT G. WILCOX, M.D.,

of Buffalo, N. Y.

(Concluded from page 170.)

A SALPINGITIS, either acute or chronic, seldom influences the menstrual period to any great degree; neither does it produce any sign of pregnancy. It causes tubal pain and produces a lump on one or both sides, but it is generally more of a constant, dull ache, accompanied, especially in the acute stage, with high temperature, rapid pulse, tense abdomen and the general signs of peritonitis. When it has passed the acute stage and the temperature and pulse have come down to nearly normal, the condition has existed so long as to throw out all question of tubal pregnancy; moreover, we can generally get a history of this acute stage having previously existed, a symptom confirmatory of the diagnosis of salpingitis.

Ovarian tumors, pelvic abscesses, fibroid growths, polypi, and peritonitis, all have their distinguishing features distinct from the one under consideration. Another exception must be noted, and that is, the tube may never rupture fully and thus the fetus may be retained there, reaching full development and viability, either to be removed alive by surgical art or die from imprisonment; but it is rare that the tube endures to full term. Indeed, it seldom holds out over three months, while the greater number rupture at six weeks.

Again, we may have the condition known as tubal abortion, in which the ovum of four or six weeks, or the fetus of three months, escapes from the tube by the way of the fimbriated extremity, carrying with it the decidua or placenta, according to the age of development. Up to the point of such escape, the conditions do not essentially vary from those just laid down, but at the moment of such abortion there is a marked shock, distinct pain and more or less sign of hemorrhage, thus varying but little from the signs of rupture. The loss of blood may be quite as severe and even fatal, as if rupture had taken place. The treatment is the same as in tubal rupture.

Thus far we have considered the symptoms produced by tubal pregnancy before and including the moment of rupture. We will now go further and note the condition weeks or months after the ovum or fetus has escaped from the tube, either by tubal abortion or rupture. We will assume that the shock at the moment of rupture was so slight that neither patient nor physician was aware that such had occurred; or the shock may have been great and the patient barely escaped with her life, and only after long weeks of suffering has she again assumed her place in the family. However that may be, our assumption is that the patient lived, but because of long-continued ill health she seeks medical advice. After the rupture, one of two things happens to the escaped ovum: either it lives or dies. If it lives, it is because it has escaped with its membrane intact and its placenta or decidua still attached, and because this placenta has been able to fasten itself upon some surface from whence it can draw sufficient nourishment for the support of the dependent ovum. This surface may be the intestines, the bladder, the omentum, peritoneum, outer surface of the uterus, or any place to which it can adhere.

Again all goes well and the ovum continues to develop as rapidly as though at home in the uterine cavity. We will assume at the fourth or sixth month, the

Rain in Parts of India.—The latest reports from India state that sufficient rain for agricultural purposes has fallen, except in parts of Baroda and in Okhamandal and Kathiawar where cattle are dying of starvation and there is scarcity of water.

patient consults a physician, believing that she is normally pregnant. She has forgotten her early history, how she had ovarian pain, gushes of blood, a little shock, some faintness, etc., because it was months ago. She only knows she is pregnant because she feels motion and she has enlarged. Why should the physician suspect that all is not right? First, because she has had more abdominal pain from the start than any normally pregnant woman should. Second, she will look anemic; the physician will be impressed that all is not well; she has most obstinate constipation and some attacks of fever, owing to localized peritonitis. The reciting of these symptoms will induce the physician to make an examination, by which he discovers that the uterus is very small for a six-months' pregnancy. The cervix is hard and contracted and the entire pelvic floor is thick and unyielding. He then asks the leading questions which will bring out the almost forgotten early history, and behold, the problem is solved and he has saved himself the mortification of sitting up nights and waiting days for a delivery which can never take place.

Next is the other alternative, namely, that the ovum perished after its escape from the tube. Here is what takes place: The escaping blood, shreds of membrane, decidua, and clots settle into various places in the lower abdomen and pelvis. Through rare good fortune, nature has sealed the bleeding points in the ruptured tube, so further danger from that source is averted; but a new danger at once springs up, namely, septic peritonitis or general septicemia. The clots and membranes have no means of self preservation, hence they must disintegrate and the peritoneum must absorb them. If, perchance, the patient has sustained this second danger and pushed through septic peritonitis, she should be rewarded with future good health; but no such good fortune awaits her. She is doomed to future invalidism unless the true condition is recognized and the right remedy applied.

How may we recognize it, even at so late a period? Only by getting a careful history from the very first of the break-down and noting every symptom carefully. The attack of peritonitis will be distinct in her mind because of its severity. The first question for the physician then to answer is, What caused the peritonitis? Women do not have such attacks without cause. Was it salpingitis, traumatism or an escaped ovum? Her story will answer it.

I recall such a case in a woman who had been treated a year for what seemed malaria. I was called in council, simply because she had pelvic pain. She told so straight a story that I was enabled to diagnose her condition even before I made an examination. One year before she had gone with a few friends on a tramp into the country; it was a few days prior to her menstrual period and she got her feet wet; she failed to flow on time but attributed it to the cold; in a few days she began having uterine pain, but no flow; two weeks passed and she suffered such pain she must needs go to bed, then came a little flow, followed a few days later by more; later came a severe pain which required her doctor in the night; she was in agony, nauseated, a cold sweat and rapid pulse. He gave her morphin for the pain and whisky for the faintness. She was confined to her bed for six weeks with what he called malarial fever, because she had high temperature and occasional chills. Gradually she got around, but was never free from pain and still had occasional attacks of chills and

fever. Upon my advice she submitted to an operation and I removed, even at that late date, the products of a ruptured tubal fetation. In the posterior culdesac was a mass of semiorganized tissue, the remains of the decidua, which was keeping up a continual septic condition, while nature was trying her best to absorb and carry it away.

The question arises, how can a woman survive a tubal pregnancy whatever may be its outcome. Some are saved from the fatal hemorrhage at the time of rupture by reason of the rupture taking place at a point remote from the placenta and ovarian artery, in which case bleeding will cease of itself, yet be it remembered that internal bleeding is always more dangerous because there is no air to aid in coagulation of blood. Again, the rupture may take place at the lower surface of the tube, and the ovum and blood escape between the two layers of the peritoneum making up the broad ligament; in that case the bleeding must be self-limited. Another question: Can a woman live with a live child in the abdomen external to the uterus? Yes, she may not only live till the child dies, because of its inability to receive sufficient oxygen from the mother, but she may live long after all vestige of such a being has been removed piecemeal from her body. Gradual disintegration may take place until the soft parts are absorbed and the bones discharged by the rectum, through ulceration, into the bowels, or they may ulcerate through the vagina or abdominal wall. Again, a fetus may reach a development of three months in the tube and there die without rupture of the tube or without causing any great amount of disturbance. In such a case the fetus becomes mummified or calcified and remains throughout the life of the mother.

The foregoing are not imaginative conditions or textbook rehearsals but bedside symptoms, as I have been able to draw them out and later verified the predicted condition by opening the abdomen and removing the product of fecundation in whatever state it was found. At a recent State meeting of physicians, I listened to a paper written by a physician, who had just seen his first case of tubal pregnancy. He with two fellow physicians had the case under observation for about six weeks. It went on to the stage of rupture and the patient was barely saved by a timely operation. He made this statement: "Up to the time of the rupture there was not the slightest symptom to suggest tubal pregnancy." In discussing the paper, I brought out the fact that there were all the symptoms one could possibly want to enable one to say positively that it was tubal pregnancy, for in relating the history of his case, he used these words: "I was called to see Mrs. X at such a date, she was suffering from very severe sharp pains extending up the abdomen from the ovary. She informed me she had not menstruated for two months. The pains were so severe as to compel her to lie down. When I saw her a few days later, she had noticed some slight flow," and so he continued to relate the course of the most typical case of tubal pregnancy I ever saw; but until after the rupture he insisted there was not a symptom to suggest it.

It is beyond my intent to enter into the treatment, but as that can be summed up in a word, I will give it: As soon as it has been demonstrated that tubal pregnancy exists, there is but one safe treatment—removal of the tube. The moment rupture has taken place, the patient stands but one chance in a hundred of recovering, unless the abdomen is opened, the tube

tied off and hemorrhage controlled. If the patient has survived this accident and has become septic, the abdomen must be opened to remove further infection. If the child has grown to full term and is alive or dead, it is next to manslaughter not to open the abdomen and save one or both victims; hence, the one word for treatment of this condition is "operation."

Two cases have come into my hands within the last few weeks, illustrating the comparative ease of recognizing tubal pregnancy before rupture.

CASE 1 was in an unmarried woman of 24 years. She menstruated normally June 4, and from subsequent events I believe that the ovum which was then on its way to the uterus became impregnated. She felt perfectly well until about June 25, when she became conscious of the right ovary by a sensation of pressure and general discomfort. She failed to menstruate July 2. She was not nauseated, but had some soreness in her breasts. July 19 (just six weeks from her last normal menstruation) she was seized suddenly with severe pains in the right ovarian region, extending up the right side as far as the kidney. She was obliged to lie down and had some faintness and nausea. A physician was called who promptly diagnosed, "stone in the kidney," and gave morphia hypodermically. She was on her feet next day and immediately noticed she was flowing slightly, which she regarded as her tardy menstruation. Two days later her pain returned with increased severity and a further gush of blood. Her physician saw another stone in her kidney and cured it in the same way as previously. For two weeks she continued having severe attacks of pain at intervals of about two days, with corresponding flow. At first she could be up and around between attacks, but later she was confined to bed constantly. At this period the "stone" doctor was discharged and No. 2 called. Because of pain in the right side and exquisite tenderness, he saw nothing but appendicitis. The fact that she was flowing every few days had no significance to him. For the next two weeks she was treated for appendicitis and was constantly urged to have an operation. She had now become very anemic, and could scarcely stand; the right ovarian region was very sensitive. On August 15 (just ten weeks from last normal period) she discharged the decidua; this was, as she described it, a mass of flesh about as large as her hand. After this she had an alarming flow; but still doctor No. 2 insisted upon appendicitis and operation. At this period, her friends desired council and one of our most prominent surgeons was called. He made a vaginal examination, discovered a lump, noticed the tenderness, diagnosed an inflamed ovary, and recommended palliative treatment. I saw her August 25, heard her history, which she gave with the greatest clearness, made a mental diagnosis of tubal pregnancy and verified it by finding upon digital examination, the right tube oblong in shape and as large as a lemon. I operated next morning, found the abdomen full of free blood and many old clots. The tube was still unruptured and I removed it in that state. By examining it carefully, I found numerous tears upon its surface, some of which were filled with small clots; others had well nigh healed. The tube was about three inches long and one inch in diameter, was a purplish black with its fimbriated extremity sealed. Upon opening it I came first to the decidua, which was nearly one-half inch thick, closely adherent to the lining of and shaped like the tube, in fact, it filled the entire distended portion of the tube; in all respects it looked like a placenta. In the center of this lay the fecundated ovum still encased in its membrane.

By a careful study of this ovum, I became convinced it did not exceed five weeks in age. The fact that it might be twelve weeks old because that time had elapsed since the last menstruation, when, it was assumed, the ovum became impregnated, is explained by the evidence that the ovum died at the first attack of severe pain, July 19, which pain was caused by a partial rupture of the tube and a consequent hemorrhage, but not an entire escape of the ovum from the tube. In fact, all of her attacks of pain were due to rents in the tube. The patient recovered perfectly from the operation.

CASE 2 followed the first in three weeks and was almost a reproduction, save that the patient did not have the sudden severe pains, because, as I found by examining the tube, there had been no rents therein. She had missed one period by two weeks then had periodic flow. She had a steady pain in the right ovarian region, extending upward, but had no temperature or pulse that would suggest salpingitis; she was nauseated and breasts sore. Her physician had called it appendicitis and called me in to operate. The history alone gave me the clue and a diagnosis accordingly made. The tube was more distended than in Case 1, the decidua and ovum larger, the latter being six weeks old and apparently alive at time of removal. Like the preceding case, the tube was removed unruptured and patient recovered.

Another case of much interest, because of the history and the conditions produced, came into my hands a few days ago. A woman, aged 35, with no children, yet married 16 years, gave a history of dysmenorrhea since puberty. During the last two years the menses were delayed at times for three and four weeks. She was unwell from July 23 to July 29, and suffered more pain than usual. Owing to vaginismus, normal copulation had been impossible until about seven days following this menstruation, when complete entrance was effected. She was well during August, but early in September began having some pelvic discomfort, amounting later to a decided pain. September 24, eight weeks after normal menstruation, on attempting to rise from the bed, she was taken suddenly with so sharp and severe a pain that she fainted. During the week following she had a slight daily flow, but did not regard it as her menses. October 2 (nine weeks from last normal menstruation) she began flowing profusely, many large clots, one of which she described as being very firm like meat and of light color. This flow lasted seven days the pain in the pelvis being constant and severe. On October 13 the pain was so severe as to cause a faintness again; she now went to bed and her family physician saw her daily. The temperature was at times 101°; the pulse, 90. She had occasional slight flow, but only about enough to stain a napkin. The family physician was in doubt between appendicitis and salpingitis. She had much pain about the seat of the appendix, for which there was reason as will be seen subsequently. I saw her November 2, she then had a temperature of 100.2°, exquisite tenderness throughout pelvis, a lump at the right of the uterus, the size of a lemon, uterus and pelvic floor rigid, slight uterine discharge. Diagnosis was tubal pregnancy with rupture, probably within broad ligament, at the seventh week. I operated November 3 and found the right broad ligament greatly distended and slightly fluctuating; on the upper surface of the ligament and toward the uterus was a tumor, the size of an English walnut. This proved to be a dilated portion of the tube; the distended portion of the ligament and tube was removed. Pregnancy had taken place about the middle of the tube and rupture had occurred at the outer or fimbriated end of the same and the blood had found its way between the layers of the broad ligament. This cavity in the ligament contained about a pint of brownish fluid of the consistency of water with blood-clots intermixed. The decidua was found in tact in the tube. It was evident rupture had taken place September 24, seven weeks from conception, and that the uterine decidua came away October 2, eight weeks after conception; fourteen weeks had elapsed from such occurrence until operation and the patient was gradually running into septic fever. The tip of the appendix was attached to the inflamed tube, which accounted for the pain in that region.

I might continue to recite numerous cases, illustrative of the various points made, but time will not permit. If I have drawn my paper out to a tiresome length, it has been with a desire to draw so clear a picture of a condition, dangerous in the extreme, that it may be recognized at an early stage by any careful man.

Typhoid at Ladysmith.—The fever-cases at Ladysmith from the date of the relief to the week ended May 18 amounted to 799. Including the above, the total admissions for all the forces in Natal during the 12 weeks ended May 27 were 2380, and the deaths 550. This would give a mortality of over 23%.

A CASE OF CONJUNCTIVAL BURN: RECOVERY
WITHOUT SYMBLEPHARON.¹

By HOWARD F. HANSELL, M.D.,
of Philadelphia.

On the evening of January 10, 1900, J. P., aged 18 years, was brought into the accident ward of the Jefferson Medical College Hospital, suffering with burns on his arms, face, and left eye that had been received from molten solder (1 part tin, 3 parts lead). An hour or two before, while going down a dark stairway, he stumbled and fell, throwing the contents of the solder can that he was carrying in his hand over the upper part of his body. The injury to the skin was insignificant, but that to the eye was very unusual. Dr. Snell, the resident surgeon, removed from the upper conjunctival sac a piece of congealed solder that was a perfect cast of the part, conforming in size and shape to the space between the lid and ball, from the upper corneal margin posteriorly to the fornix and extending laterally nearly a centimeter on each side of the median line. The cast was concavo-convex, very thin, and measured 1½ cm. by 1 cm. After thorough cleansing of the eye, Dr. Snell instilled fluid vaselin and applied ice water compresses during the night. The following day the opposed conjunctival surfaces of the upper sac were denuded of their epithelium, swollen and white, and the cornea showed signs of injury in the loss of epithelium and of transparency of its upper half. Hot water bathing was substituted for the cold compresses, atropin was instilled, oil injected into the superior culdesac, and the lid separated from the ball many times daily by the probe and by the fingers.

The cure progressed uninterruptedly until January 15, when my colleague, Dr. deSchweinitz, assumed charge of the case. The opacity of the cornea had given way to renewed transparency, the edema of the conjunctiva had disappeared and no symblepharon had formed. The swelling of the lids that had been of high degree had entirely subsided, and the patient was nearly ready to leave the hospital.

CONGENITAL TUBERCULOSIS.

By BENJAMIN F. LYLE, M.D.,
of Cincinnati, Ohio.

On December 2, 1899, B. P., female, single, colored, aged 32 years, was admitted to the Cincinnati Branch Hospital for Consumptives. Her family history was incomplete; her father and mother were both dead from causes unknown; her only brother died of consumption. She had had one

throat and incontinence of urine. She had never been sick before, but had been intemperate. She had an attack of hemoptysis two years before, losing a large quantity of blood, and since then had only expectorated small quantities; had profuse night-sweats for past year. She was pregnant, presumably in the seventh month. The temperature was 101.6°; pulse, 104; respiration, 30. She was not weighed; height, 5 feet 2½ inches; circumference of chest 26 inches, expansion one-half inch. Physical examination: Palpation, negative because of weak voice. Percussion, right anterior; tympanitic resonance above fifth rib, dullness below. Right posterior, tympanitic resonance above fourth rib, dullness below. Left anterior, dullness over entire area. Left posterior, dullness over entire area. Auscultation, whispered pectoriloquy, cavernous breathing and coarse rales over tympanitic areas. Bronchial breathing over remaining areas. The urine contained albumin. She was very much prostrated and usually delirious.

On December 15 she gave birth to a child. How long she had been in labor it is impossible to surmise; she was in the room with a number of patients and had not indicated by her actions that anything unusual was transpiring. The first intimation of labor was the crying of the child. The placenta came away naturally and presented no pathologic changes, the uterus contracted well, and the patient appeared oblivious of her travail; she was cognizant of the birth, however, as she asked to see the child, after expressing regret that it was not a boy, she named it. She remained in a somnolent condition until her death, which occurred on December 17.

One of the most interesting points in her history is the fact that she was able to carry and give birth to two living children while a victim of tuberculosis.

Postmortem examination: Pleurae thickened and adherent over both lungs. Upper and middle lobes of right lung honeycombed with cavities. Lungs consolidated except at bases. Heart normal. Small intestines ulcerated and mesentery congested. Kidneys congested and small extravasations seen throughout cortices. Uterus size of cocoanut and apparently normal.

The child weighed 3½ pounds when born, and apparently had reached full term. It was always very weak, and about the only animation it displayed was to move its head when its attention was attracted, to manifest hunger by crying or contentment by sucking its finger. Its weight slowly increased during the first 8 weeks to 5 pounds, and then decreased to 4½ pounds, its weight a few days before death.

The temperature was subnormal during the first 4 weeks, varying between 96° and normal, the latter sometimes being the evening temperature. For 12 days the temperature showed a slight rise above normal, this

child which died 4 months previous to her admission, the child was 18 months old, the cause of death unknown. Patient gave a history of having been sick two years, and complained of a severe cough, profuse expectoration, sore

was followed by hyperpyrexia which did not subside until the vital forces reached a very low ebb during the last week of the child's existence. The accompanying chart will illustrate the temperature-changes. Like all children fed artificially, it had indigestion at times, the

¹ Read before the Section on Ophthalmology, College of Physicians, Philadelphia, April 17, 1900.

stools containing curdled milk and being of a greenish color. It had a good appetite until the second week before death; but the last week took its food with avidity.

Postmortem examination: The child was very much emaciated, and the soft parts over the ribs were no thicker than parchment. The lungs were filled with myriads of minute caseous tubercular deposits, some of which had coalesced, one of the masses in the left lung being a centimeter in diameter. The spleen and liver showed deposits as numerous as in the lungs, and in the same caseous condition. The kidneys had a few caseous deposits scattered through the cortical substance. The bronchial glands were much enlarged. The masses contained tubercle-bacilli. Intestines and mesenteric glands normal.

That this is an instance of congenital tuberculosis we believe for the following reasons:

The child was removed from all danger of inspiring the germs by being kept away from the wards.

That disease was not contracted through the milk is shown by the freedom of the intestines and the mesenteric glands from indications of disease.

The child was evidently ill at birth, this is shown at first by the subnormal temperature; after the child gained strength, the temperature became elevated and continued so long as the vitality of the child would permit. The temperature-curve throughout is characteristic of tuberculosis.

The enormous number of deposits in various organs, all in the same stage, indicates a synchronous infection through the blood of the child. The only source of the bacilli could be the mother's blood.

ANTISTREPTOCOCCIC SERUM—A CASE IN WHICH IT WAS USED WITH APPARENTLY REMARKABLE RESULTS.

By D. H. GALLOWAY, M.D.,
of Chicago, Ill.

On January 31, 1899, I was called to see a young lady who was suffering from sore throat. A red rash had covered her body a few days before, and I would have made a diagnosis of scarlet fever had I not known that she and the four other children in the family had had scarlet fever a few years before. Eleven days later I was again called to this family, this time to see an older sister, a young lady 22 years of age. I found her with a sore throat, temperature 102° F., and with a scarlet rash covering nearly the entire body. A third sister had developed a similar rash a week before, but as she did not seem to be very sick it was not thought necessary to call a doctor. I made a diagnosis of scarlet fever this time, and the diagnosis was confirmed by a fourth member of the family coming down with the disease a few days later, in whom it ran a typical course.

On February 16 the patient's temperature was 103.5° F. On the 17th it was 102°; teeth and tongue were very sore and covered with a heavy, white coating. The glands on both sides of the neck were enlarged; on the right side one was particularly large and tender. The patient's mouth was washed and sprayed every hour with Dobell's solution or some other antiseptic, and I treated it every day with a saturated solution of copper sulfate on a cotton swab. For the next 5 days the local conditions grew steadily worse; the tumor on the right side of the neck was now the size of a man's fist, head turned to the left and rigidly fixed, mouth could not be opened more than $\frac{1}{2}$ of an inch. Patient could swallow nothing but liquids, and those only with great difficulty and pain. A culture had been made from the throat but no diphtheria-bacilli found.

February 22 a consultation was had with a surgeon and a laryngologist with a view to operation on the tumor as it threatened suffocation. They both advised against an operation, as it was believed that the patient could not take an anesthetic on account of the condition of her mouth, nose, and throat. Local applications to the mouth were no longer

possible, and it seemed that nothing further could be done but let the disease take its course. We believed the swelling to be a streptococcic abscess and determined to try antistreptococcic serum. On February 23 I administered 10 cc. of this serum. On the 24th I believed the abscess had ceased to enlarge, and I administered another 10 cc. of the serum. On the 26th the abscess was certainly smaller, and the third dose was given. On the 27th and 28th the serum was repeated, and on the latter date the abscess was not one-quarter as large as it had been when the treatment was begun. I had now given 6 doses of 10 cc. each, and the medicine was discontinued. The temperature was 100.5° F. when the serum-treatment was begun, and it continued at about that point throughout, falling to 99° on the morning of the 24th, 25th, and 26th, but rising to 102.4° on the afternoon of the 28th.

On March 1 the patient was able to open her mouth, and I treated the entire surface with the copper sulfate. When I pressed on the roof of her mouth with the cotton swab, pus oozed out around the margins of the upper teeth. The mucous membrane was separated from the upper teeth by a necrotic line perhaps $\frac{1}{2}$ of an inch wide completely around the upper arch both inside and outside. From this space pus was continually oozing, particularly when the swollen tissues were pressed upon anywhere in the neighborhood. This pus contained staphylococci. Another culture was taken on the 27th, but no diphtheria-bacilli were found. On March 2 a troublesome urticaria developed on the body and face and continued with more or less severity for 3 or 4 days. Day after day I cleansed the mouth with a solution of copper sulfate and other antiseptics and a steady but slow improvement was noticeable.

The coating on the tongue did not get any less and on careful examination I found it to consist of slender filaments from a quarter to a half inch in length, growing vertically from the surface of the tongue and as close together as they could stand. I tried all sorts of antiseptics, even to strong solutions of formaldehyd, without avail. I then pulled off some of the filaments with a pair of forceps and found that they left the mucous membrane smooth and red but intact as it did not bleed. I then cured the tongue removing the growth completely. On examining this material with the microscope I concluded that it was a fungus, but a kind that I had not before seen. I submitted some of it to Dr. Jaques, Dr. Gehrmann, and others who are expert with the microscope, but none could identify it. Various culture-mediums were inoculated but in no case was there a growth of the filament. Some of it was sent to the Division of Botany of the Agricultural Department at Washington and they reported that it was not a fungus at all, but probably sarcoma. They sent some of it to the Johns Hopkins University, but I have not heard their opinion of it. I am now of the opinion that it was an outgrowth of the epithelium.

On March 8 there still remained a small indurated mass where the supposed abscess had been, but on the 14th no trace of it could be found. The enlarged glands were decreasing in size. March 22 the patient was able to be up, but convalescence was very slow and she remained weak for many months. Her hair fell out completely and was very slow in coming in again.

The pulse remained between 70 and 90 till March 3 when it went up to 130 and remained at or near that point for four days; temperature ranging from 100° to 102°. On March 7 pulse and temperature were normal and did not again rise.

Unfortunately we have no positive proof that the swelling in the neck was a streptococcic abscess. If it was, there can be little doubt that the antistreptococcic serum saved the patient's life, for neither of the consultants believed she would survive either with or without an operation.

VOL. VI, No. 6

AUGUST 11, 1900

\$3.00 PER ANNUM

The Assassination of King Humbert.—Medical science cannot ignore the diseases of the body politic, for these, unfortunately, are too often but evidences of disordered mental and physiologic processes in the people. The assassination of the Italian king is a symptom of a malign social disorder. Apart from its political and strictly personal aspects, it has importance as an indicator of a widespread moral and intellectual degeneracy for which the present era in more ways than one is becoming entirely too conspicuous. We are passing through an epidemic of assassination which within a few years has claimed for its victims a czar, a president, a prime minister, an empress, and a king. This list does not include our two American presidents whose murderers were actuated by somewhat different motives. That this epidemic has spent its force is by no means evident. Abortive attempts to kill princes, statesmen and shahs are reported with some degree of periodicity, while threats to kill are uttered by redhanded anarchists with impunity, and published with promptness by the daily press. The truth is the world has not yet learned how to meet and to treat this disorder; least of all has it learned that the imperative duty is prevention and restraint. The public does not take heed from the teachings of science, and learn to estimate at its full value the mental degeneration of the times. Under the panoply of freedom of speech anarchistic fanatics are today in this country assembling and propagating their kind. Imitation is the obscure psychologic law that leads these creatures on. What one has done, another also can and will do. This is a principle of psychiatry that is well enough understood in the asylums but not in police stations and the courts. The fire must be stamped out in the bush before it has spread to the whole forest. These political paranoiacs who commit murder aim at a bright and shining mark because thereby some imaginary luster is shed upon their deed. They kill for glory more than for revenge. They desire to be talked about and to be imitated, for they know that "the youth who fired the Ephesian dome, outlives in fame the pious fool who raised it."

The Plague in London, Yellow Fever in Florida, and Smallpox in Cape Nome.—The Marine-Hospital Service reports the receipt of a cablegram, dated August 3, from Past Assistant Surgeon A. R. Thomas,

who is detailed for duty at the United States Consulate-General in London, to the effect that two deaths from plague had just occurred in the English metropolis. The diagnosis had been confirmed by bacteriologic examination. No details were given as to the origin of the cases. The Marine-Hospital authorities think that the precautions taken at our own ports are sufficient to safeguard this country from the disease. It is probably too soon to feel alarm, but this outbreak of the plague is unpleasantly near.

From the same authority at Washington we learn that on August 2 Surgeon J. H. White reported two cases of yellow fever in Hillsboro County, Florida. This is only a small beginning, but it is still early in the season, and these cases may serve as reminders that the annual problem regarding yellow fever is before us. The United States Marine-Hospital authorities have shown their ability to combat the disease successfully on former occasions, notably at Hampton, Virginia, last year, and we may feel confidence in their alertness and competence. They do not place their reliance on shotgun quarantine, but on scientific methods.

From far-distant Cape Nome, in Alaska, comes the report of the prevalence of smallpox among the gold-hunters. Up to July 10, 22 cases had been reported. The patients had been removed to a camp outside the town as soon as possible after discovery, and every means had been taken to prevent a spread of the disease, but from local conditions and lack of facilities Lieutenant Jarvis reported that there was great danger. The United States has established quarantine stations in Alaska. From these several reports it is seen that from various quarters there are threats of epidemic disease. To be sure, their geographic centers are widely separated, but geography in these days of steam is a local affair, and it is well to be on guard. Fortunately, no extensive prevalence of disease has been reported among the troops in China.

The Famine in India.—This visitation is an almost unprecedented tragedy. If reports are true the government in India is providing for six millions of people daily. The highest mortality is naturally in the native States, where the government has little control. In the worst stricken sections 60,000,000 of people are more or less affected, and one-sixth of this number are threatened with death by starvation. The worst of it is

that the prospects of relief from natural causes are exceedingly poor. Not much rain had fallen at the last reports, and even if the rain does come in abundance the poor tillers of the soil have no seed to plant. Hence, relief is needed literally from the ground up. The cause of the famine, as is usual in densely crowded countries, was a failure of the crops. These crops must now be provided for in another planting, and yet, so pathetic is the situation, there is nothing to plant. The suffering, to be appreciated, must be seen, and, thanks to the camera, it is being seen in highly realistic photographs, which are being sent to the ends of the earth. These represent the wretched natives grouped in all the horrors of emaciation and death. The Citizens' Permanent Relief Committee of Philadelphia publishes some of these dreadful pictures along with its circular asking for aid. They utter an appeal more eloquent than words. It is something to the credit of American philanthropy that with all our urgent foreign cares, not to speak of our own domestic needs, we are not forgetting these poor starvelings in far away India. Three cents a day will save a life. The treasurers of the fund are Messrs. Drexel & Co.

The Plague Situation in San Francisco.—A careful perusal of the official correspondence of the Marine-Hospital Service as published in its weekly *Bulletin*, and consideration of the various scientific articles contributed to current medical literature by members of the profession of San Francisco, leaves little doubt that a disease corresponding in all its essential particulars to the bubonic plague has existed in San Francisco. That all of the cases but one have thus far escaped recognition until after death does not invalidate this conclusion. When commercial cupidity and false local pride have arrayed themselves in line with the general ignorance of profession, it is not to be wondered at that the initial cases have not been recognized before death.

The situation as it exists today is a grave one. The scientific workers of the local health-board and of the Marine-Hospital Service concur in pronouncing the disease to be plague. The Chinese population, the Six Companies, a large proportion of the medical profession, the daily newspapers, the Governor of the State, and the judge of the United States Court all unite in saying that the disease is not the plague. In consequence of the decision of the United States Court it has been necessary for the President to nullify the quarantine proclamation of the Marine-Hospital Service formerly approved by him. This does not mean that the President disapproves of the quarantine, but that as a law-abiding citizen he feels bound by the decision of the court until such time as that decision is reversed, if it ever should be. It was most unfortunate that the revocation of the quarantine proclamation should have followed shortly upon a very peculiar, intrusive and characteristic political message from a delegation of

California politicians, demanding such action upon pain of political defection. There are no good grounds for supposing that the political appeal had any influence in deciding the course of action of the President; that action was in all probability due solely to respect for the decision of the court.

That the court erred, and erred most grievously in presuming to decide adversely to the health authorities, who had done a difficult duty with courage, determination, and good judgment, as rare as it was commendable, can hardly be doubted by those who have studied the full reports of the situation. That the health authorities themselves also erred in permitting the representatives of the Six Companies to delude them by promises of cooperation in certain measures, thus getting in a false position before the public and the court, seems also to be the case. Yet the very error in this respect on the part of the health authorities is but the more convincing evidence of their sincerity in belief and their propriety in action. That they were tricked and that the court sustained the tricksters simply reflects more credit upon the integrity of the health-officers and less credit upon the other persons involved.

The situation is such that the precautions already taken may possibly have proved effective in limiting the spread of the infection, but this is not likely. The developments of the succeeding year will prove whether or not the sporadic cases that have thus far occurred have as yet sufficiently infected the city to establish either an endemic or an epidemic next winter. If the city should be exempt, the credit will be due to the work already performed by the faithful officers of public health,—but the people whom they represent will probably give them neither thanks nor recognition. If, on the other hand, an epidemic should occur, the Six Companies and the court should have the credit for such occurrence,—but the public will probably fail to give credit where it is due in that event also. All of which goes to show that duty must be done (in public-health work, at any rate) for its own sake.

Monogamy, Longevity and the Diseases of Late Life.—The increase in the death-rate from carcinoma in recent years has directed considerable attention to the causation of this affection, and many have believed that it was owing to the increase in the average length of life into the carcinomatous age now more than formerly; but in an article discussing this subject, Harry Campbell (*Lancet*, June 9, 1900) contends that it is monogamy that tends to favor the increase in our race of all late-life diseases, carcinoma among others, and to shorten the vital span. The world is filled with a vast multitude of the unfit, people who fall short of the standard which makes life worth living, who, in virtue of their unfitness, suffer more than they enjoy. The ability to live into the sixties and seventies, or longer, we owe to the vigorous man of fine physique, who re-

tains his procreative power into advanced life. Woman, on the other hand, has played no part in the evolution of this power; her ability to live beyond 40 or 45 has no racial influence, since it does not increase her opportunity of leaving offspring to inherit it. The majority of civilized men have children by one wife only, and she is generally about the same age as her husband, the result of this is to reduce the age-limit of reproduction in the man to that of the woman. Monogamy reduces the superior man to the reproductive level of the inferior man, and this fact is to increase the racial tendency to diseases after middle life, and to shorten the vital span. While, however, monogamy is thus exercising an injurious influence on our race, polygamy is a sociologic impossibility. The best and only way to raise the racial standard is for the unfit to submit to voluntary elimination by abstaining from marriage.

Interesting as are Campbell's statements we can not believe that they are entirely correct. In the first place we doubt if the racial standard will ever be greatly elevated by the voluntary abstinence from marriage of the unfit; indeed the unfit are usually most likely to marry and have numerous children, and the worst of their class very often have numerous illegitimate children. Other things being equal, we doubt if facts will show that the child begot by a man in advanced life is more vigorous and more likely to live to a healthy old age than the child of the prime of his life; that is, if a vigorous man be married twice to equally healthy women, to one in the most vigorous period of his early manhood, to the second one in advanced life, we believe that the child of the period of his greatest powers is more likely to attain a good old age than the child of his declining health and strength. Moreover, we believe that Campbell much underestimates the importance of a vigorous maternal ancestry. Stock-raisers well understand that no matter how worthy the sire, it is impossible to raise the finest blooded stock without a good mother, indeed the mother seems much more likely to transmit her powers to the child than the father, and there seems no good reason why she should not transmit the tendency to longevity in as great a degree as physical and mental peculiarities. Are not the tendency to monogamy in all civilized races and the limited reproductive life of the female Nature's wise selective factors in evolution which make it improbable in most cases that either the male or female shall propagate their kind at any period except during their greatest health, strength, and vigor? And are not these factors beneficial rather than detrimental to the moral, mental, and physical progress which we know has been made by the human race?

The Adulteration of Food.—In a speech delivered in the U. S. Senate on May 2, Hon. William E. Mason made a strong plea in favor of legislation for pure food. Senator Mason spoke as chairman of a com-

mittee appointed by the Senate to investigate the adulteration of food-products in this country. The extent to which such adulteration is carried on is simply amazing. This committee summoned many of the leading expert chemists and hygienists of the United States, and their evidence, as published by the Government, especially on the subject of baking powder, is most enlightening. Senator Mason himself spoke chiefly on this subject of baking powder, but he did not entirely ignore other articles. For instance, he spoke of honey (so-called) in a jar of which it was proved by analysis that 1% was real honey, with a little honeycomb on the top, and the rest glucose. This stuff is, of course, a fraud on the purchaser, although it is not injurious to health. It seems that many industries are engaged in palming off glucose as various kinds of jellies—for instance, apple, peach, etc. The parings of the fruit are used to impart a flavor, and the cheap glucose does the rest.

But the worst features of these frauds are found in those adulterations which are not merely "sophistications" but are directly injurious to health. The chief of these is baking powder. The old-fashioned baking powder is made of cream of tartar, which is a product of the grape. It supplies an acid which, uniting with the bicarbonate of sodium, liberates carbonic-acid gas, and thus leavens the dough. In order to secure this liberation of carbonic-acid gas by means of a substance less expensive than cream of tartar, a class of manufacturers in this country began about 25 years ago to substitute alum. This salt, which is a double sulfate of aluminum and another base—either potassium, sodium, or ammonium—supplies the acid (sulfuric) which attacks the sodium bicarbonate, and thus sets free the carbonic-acid gas just as in the case of the cream of tartar. But, unfortunately, in this chemical reaction between ordinary alum and sodium bicarbonate, there is left aluminum hydroxid, with perhaps some other basic compounds, especially the phosphate, and some of the original sulfate which has not undergone complete change. It was contended for a while by the manufacturers that nothing was left but the hydroxid and phosphate of aluminum, and that these, being insoluble, were inert. Chemical research, however, has demonstrated that these substances are soluble in weak acids (such as the acid contents of the stomach) and hence may be absorbed and act as poisons; moreover, some of the original alum (the double sulfate) is not changed in the ordinary process of bread-making, and it too may act in the same way. Whether these substances are absorbed in sufficient quantities to be injurious to health may be an open question, but that they may at least act as local irritants upon the mucous membrane of the stomach and thus disturb digestion, seems not to admit of doubt.

Senator Mason, who deserves great credit for his ex-

position of this subject before the U. S. Senate, said that alum baking powders were prohibited by law in most of the countries of Europe. The question remains, are the cream of tartar powders entirely harmless? Is the Rochelle salt, formed by reaction in baking and which remains in the bread, muffins, etc., of no consequence? Certainly it is of no practical hygienic significance when only a couple of breakfast muffins, prepared from a cream of tartar baking powder, are eaten. How about the matter when all the bread, muffins, biscuits, etc. are baked with such powder? In this case we suspect that a strong case could be made out against the use of this powder also. Small and repeated doses of Rochelle salt are absorbed and give the urine an alkaline reaction. Its laxative tendency is still manifest when the doses are not too small. For one pound of flour about 3 rounding teaspoonfuls of cream of tartar are used, say $\frac{1}{2}$ ounce. The resulting Rochelle salt would weigh more. We think that all baking powders, except in the preparation of muffins and fancy breads, which should constitute only the smaller and accessory part of the bread-diet, should be avoided.

Air Embolism During Surgical Operation.—J. Basil Hall (*Quarterly Medical Journal*, for Yorkshire and adjoining counties, England, May, 1900) relates a case in which embolism occurred during the removal of a recurrent growth of the breast. The mamma, together with the pectoral muscle, had been turned back according to Halsted's method, and a somewhat extensive mass of glands was being dissected out at the apex of the axilla. A small vein had been cut across, so insignificant in size that pressure forceps were not applied at the moment. A loud sucking noise was heard, precisely like that produced by a small puncture in the pleura. There were three distinct inspirations of air before the vein was clamped, as the patient was breathing rather rapidly at the time, the ether inhaled having just been reapplied after an interval for refilling it. Within a few seconds there was a sudden stoppage of respiration, followed by four or five inspiratory gasps; extreme pallor overspread the face, the pupils dilated widely; there was a slight tetanic spasm of the body and risus sardonius of the face. The pulse became fluttering and imperceptible, but the heart continued beating rapidly and tumultuously, while a distinct thrill was perceptible to the hand placed over the precordium. The muscles relaxed, all respiratory efforts ceased, the heart-beats became imperceptible and the patient was to all intents and purposes dead. The whole period, from first hearing the entrance of air to the final stoppage of respiration, was not longer than 15 or 20 seconds. Artificial respiration was at once begun and vigorously carried out, while a large dose of strychnin was administered hypodermically. After an interval of a few minutes a spontaneous inspiratory effort occurred. Respiration was restored after a lapse of 15 minutes. The operation was then hurriedly completed. The patient remained in a somewhat critical condition for an hour or two, but ultimately made a good recovery. The surgeon who has once experienced such accident will take pains to clamp all veins before dividing them when operating in dangerous regions, more especially when the vessels are being dragged on by the necessary manipulation of the part, since inspiration of air cannot occur in a wet wound. The first thing to be done, if the opening cannot be seen, is to flood the wound with any fluid that may be at hand. Vigorous and persistent artificial respiration must be persevered with, together with the injection of cardiac stimulants. If immediate syncope does not occur, and cardiac distress continues, bleeding to relieve the right side of the heart will do most good, but bleeding undertaken with the view to empty the air from the veins is useless. [M.B.T.]

Reviews.

The Medical Diseases of Childhood. By NATHAN OPPENHEIM, M.D. (Coll. P. & S., N. Y.), A.B. (Harv.). Author of "The Development of the Child;" Attending Physician to the Children's Department of the Mt. Sinai Hospital Dispensary. With 101 original illustrations in half-tone, and 19 charts. 653 pages. New York: The Macmillan Company, 66 Fifth Avenue. Price, \$5.00.

This book will constitute a valuable addition to pediatric literature, and is a concise statement of the present status of knowledge on the subject. The aim to present it in a philosophical and logical way, with the avoidance of details and statistics, is well carried out; the sections on treatment are possibly a little too brief to be of great help to the pediatricist. The book is well-balanced and well-written, and although it is difficult to single out chapters for special mention, noteworthy ones are those on Development, General Hygiene Examination and Diagnosis, and Diseases of the Bronchi, Lungs and Pleura. As in every book, minor mistakes occur, which will of course be corrected in the second edition, which we predict will soon be reached. We cannot accustom ourselves to the author's use of the word "tract" for "tract" in referring to a system. More serious errors are found on pages 80 and 191; on the former the statement is hard to believe that a quart of milk will give only 2.5 grams (about half a teaspoonful) of 8% cream; on the latter, in the prescription, the dose for strychnin has changed places, in Apothecaries' weight, with that for aloin and belladonna. The illustrations are good half-tones of very good photomicrographs and have been chosen with judgment, there being but one (Fig. 34) whose presence, perhaps, would not be missed.

Die Technik der Speziellen Therapie. (The Technique of Special Therapy) By PROFESSOR F. GUMPRECHT. Second and enlarged edition. Jena: Gustav Fischer, 1900.

To nearly all practitioners, and to every hospital resident, this work is certainly a godsend. It discusses all forms of technical manipulations, the method of use of apparatus for special therapy, the manner in which it should be prepared, the details of its use, the indications for repetition in its use and the various practical points which are so often difficult of decision for those who are inexperienced. As examples, the work begins with the discussion of the various methods of puncturing and incising the skin of anasarca. This is followed by a discussion of the use of transfusion, then follow the various methods of treating the esophagus by sounds and other instruments, the use of the stomach-tube and other apparatus, which may be necessary in the management of diseases of the stomach and intestines, and following this there are descriptions of the instruments used in treating diseases of the upper air-passages, and the methods and indications for their use. Thoracocentesis and paracentesis of the pericardium, puncture of the abdomen and lumbar puncture are discussed, and the final portion of the book is devoted to instrumental methods of treating diseases of the urinary passages. The book, as the author states, discusses the small details which so readily lead one into embarrassments. It considers the questions as to whether the procedure is difficult or not, whether it needs previous practice or special experience, exactly what indications should lead one to carry it out, and at what time it should be done. All the instruments necessary are listed, in order that one may be prepared with everything on the table by his side. The possible complications that may appear in the procedure are noted, and the subsequent treatment is discussed. The work is purely practical, and it fills a need that has been very evident. The second edition appears only about a year after the first, indicating the favor which the former edition has met. A number of new procedures have been introduced and are discussed; for instance, infusion of salt-solution the treatment of typhoid fever, subcutaneous nourishment, cocaineization of the spinal cord, and other recent procedures.

The Clinical Examination of Urine, with an Atlas of Urinary Deposits. Forty-one original plates, mostly colored. By LINDLEY SCOTT, M.A., M.D. Philadelphia: P. Blakiston's Son & Co., 1900. Price, \$5.00 net.

In the 49 pages of text in this volume, Dr. Scott discusses briefly certain general considerations, the composition, the physical properties, and the normal and abnormal constituents of the urine; he refers briefly to the bacteriology and toxic properties of the urine and to the examination of the urine for life insurance; and he finally gives a table indicating the leading characters of the urine in disease. This portion of the book is eminently concise, practical, and to the point. No attempt is made to detail all the tests that have been proposed for the determination of the normal and abnormal constituents of the urine, but Dr. Scott mentions only those that he himself had found especially useful and trustworthy. Thus he prefers the potassium ferrocyanid and acetic acid test for the detection of albumin, and he says of the heat and nitric acid test, that it is neither delicate nor trustworthy—a statement to which some will take exception. He also mentions that more mistakes are made in the use of Fehling's test for sugar in the urine than in the use of any other urine test, and that the phenylhydrazin test is the best for the determination of sugar—statements that can be heartily endorsed. The 41 plates, many of which are appropriately colored, are in general good and convey an excellent idea of what they are intended to portray. Some of them, however, are poorer than we would expect in a volume selling at the price for which this is offered. The volume is neither the best book on the chemic investigation of the urine nor the best atlas of urinary deposits, but as an eminently practical guide to the clinical examination of the urine must it be commended.

The Students Hand-Book of the Surgery of the Alimentary Canal, being an abridged and amended edition of the author's treatise on the same subject. By A. ERNEST MAYLAND, M.B., B.S., Lond.; Surgeon to the Victoria Infirmary at Glasgow; External Examiner in Surgery to the Victoria University, Manchester; Examiner in Surgery for the Fellowship of the Faculty of Physicians and Surgeons of Glasgow. Pages 510; 97 illustrations. Philadelphia: P. Blakiston's Sons & Co. Price, cloth, \$3.00.

As stated in the title, this volume is an abridged and amended edition of the author's larger and well-known work upon this subject. The volume is divided into 4 sections; the first 92 pages are devoted to the consideration of the surgical affections of the esophagus; the second part, comprising the next 72 pages, is devoted to the stomach; the third part is divided into 3 sections, the first dealing with the duodenum, the second with the jejunum and ileum the third with the large intestine and appendix; the fourth section of the book is devoted to diseases of the rectum. In concise form a large amount of important information is given with regard to the very common surgical diseases of the alimentary tract. The book shows evidence of the author's wide reading and study, and its teachings, for the most part, are modern and reliable. Certain sections need revision, however; in the consideration of the operative treatment of gastric ulcer the author fails to notice any of several valuable papers which have appeared in American literature since 1896; in considering the treatment of typhoid perforation he quite properly states that, "not to subject the patients to laparotomy under such circumstances is to fail in carrying out the only and proper means of saving life," but, as in the treatment of gastric ulcer, the latest and most exhaustive sources of information have evidently not been consulted. Thrombosis of the mesenteric vessels is considered, a topic which has been very commonly omitted by writers on this subject; however, no definite instructions are given as to the indications for operations or methods of operative procedure. In a small book brevity is to be expected and is quite excusable, but entire omission of certain topics seems to us hardly justifiable in a

special volume of this kind. Among such omissions we notice that there is no mention of the operative measures which have been employed in the treatment of hour-glass contraction of the stomach, gastrolisis is not mentioned, nor is there any mention of the use of the Laplace forceps or any of its modifications in intestinal anastomosis. While there are several minor failings of this kind, the teachings of the book are, on the whole, very trustworthy and it should prove a very valuable aid to the general practitioner for whom the book was primarily intended.

Correspondence.

A KINDLY WORD FROM BUFFALO.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

AN exceedingly interesting editorial, entitled "A Great Light from Philadelphia," appears in the August issue of the *Buffalo Medical Journal*. It comments in a delightfully caustic and breezy way on an editorial on The Reorganization of the New York State Medical Association, in the PHILADELPHIA MEDICAL JOURNAL, of July 21. It is not worth while to dissect the so-called criticisms of the article, as time is far too valuable.

The editorial criticised was evidently written by one who has been thoroughly conversant with medical matters in the State of New York since long before the State Medical Society degenerated into a machine manipulated in the interests of and by a clique composed of less than half a dozen men. If the writer of the *Buffalo Medical Journal's* editorial is a member of the State Society he is either young and guileless, complacently ignorant that when the string is pulled he dances to the whistling of a one-man band, or he has passed the period when live issues appeal to his cerebration. Whichever it may be, it is evident that he has not even the remotest knowledge of the subject he has allowed himself to write about. This man, in elegant phraseology, says: "How empty of think is one's think-tank who concludes a ponderous paragraph for the enlightenment of the American medical profession as to the history of the profession in the State of New York and its State Society, with the idiotic conclusion that because 'The State Society now numbers about 600 members out of an estimated total of 9,500 medical practitioners in the State,' therefore the former cannot represent the latter." Considering the manner in which the latter are represented, as a matter of fact, the statement does not seem so idiotic, after all. If the *Buffalo Medical Journal* will study the signs a bit it may not prove a disadvantage. The fact that several of the County Medical Societies have seceded bodily from the State Society and applied for charters from the State Association is an indication of the way this representation is regarded. The additional fact that the membership in the State Association was increased by nearly one thousand in less than two months, when the plan of reorganization was made known, is significant, to say the least. This plan of reorganization will be acted on by the State and County Associations in October next. It perhaps would be wise for editorial solons to trim their sails in accordance with the direction of the wind; if not, they may soon be sailing in a handicap race all by themselves.

In conclusion, with the extreme courtesy and good will, I venture to recall a sentiment once uttered by Dumas, the younger: "*Dieu a fait les imbéciles pour que les gens d'esprit regrettent moins la vie.*" And to this I would add the advice. Read, learn, and digest!

ONLOOKER.

Special Article.

SOME INCIDENTS IN THE EVOLUTION OF THE MODERN PHYSICIAN.¹

President's Address Delivered at the Sixty-eighth Annual Meeting of the British Medical Association.

By WILLIAM ALFRED ELLISTON, M.D.,

Senior Surgeon, East Suffolk and Ipswich Hospital.

THE progress of medicine was traced step by step from the beginning of the sixteenth century and the effect of each step on the evolution of the profession fully analyzed. The great men of each period were also considered in their relation to the general progress and the effect of Parliamentary measures traced.

The important legislation of the nineteenth century was the Apothecary's Act of 1815. This Act has been proved to be one of the greatest boons ever conferred upon the medical profession, and whatever may be the sentimental objection to a learned profession being connected with traders, we are bound to remember that to those who sought the Act of 1815 we are indebted for a reform which has been far-reaching in its results. Previous to this Act the education of the medical practitioners of England and Wales was entirely optional on their part, and although many of them possessed degrees or licenses of the universities or colleges, the greater number possessed no such qualification, and many of them were wholly illiterate or uneducated. About the year 1850, a preliminary examination in arts was instituted as a necessary and independent requirement before proceeding to the medical curriculum. In 1858 the Medical Act became law, and by this Act the L.S.A. of London was permitted to practise through Scotland or Ireland. The Apothecaries' Amended Act passed into law in 1872. Women were admitted to practice in 1876. In 1878 the pharmaceutical chemists were licensed by Act.

It is worthy of observation that the State has hitherto not interfered to prescribe the subject-matter, or the minimum standard of medical examination, although there has been at least one attempt by the Government of the day to establish a uniform minimum. Under the beneficent legislation of the century, and particularly by the establishment of the General Medical Council, jealousies between the different branches of the profession have mainly disappeared, it is difficult now to realize that at the commencement of the present century it was far otherwise, then we find a young physician advanced by his college in 1808 as a reward for a pamphlet against the growing pretensions of army surgeons.

Increased desire for knowledge of anatomy and surgery had a remarkable effect. At the early part of the century, with some few exceptions, very few surgeons, even of large hospitals, had personally dissected the human body; and the demand then for subjects became so great that a disreputable association had to be entered into between the teachers of anatomy and a class of men who were termed "Resurrectionists," to supply them with subjects. The sums paid to these body-snatchers were frequently exorbitant, and a scandal arose which at the time created a great sensation, as, in addition to the many indecencies undoubtedly committed, it was alleged that murders were incited. The excitement was happily allayed by the passing of the Anatomy Act of 1832, which, by affording facilities for the practical study of anatomy, gave a great impetus to study in this country.

One of the curious features at the early part of this century was the continuance of the system of private medical teaching. Some of these schools attained a great degree of prosperity.

It was at Grainger's School that the body of the English philosopher, Jeremy Bentham, was dissected and lectured upon, in accordance with his will, by his friend, Dr. Southwood Smith; after the examination his body was embalmed and dressed in his clothes and is still preserved at University College, London. During the ceremony a violent thunder-storm shook the building, but Smith proceeded with a clear unflinching voice, with a face as white as the dead philosopher's

before him. Brougham, Grote and Mill were present at the examination of their dead friend.

The growth of the medical press and the influence it had upon the medical profession commenced with the efforts of William Sharman, M.D., who was at Harwich in 1767. He commenced in 1810 to edit a periodical, which was styled the *New Medical Physical Journal or Annals of Medicine, Natural History, and Chemistry*. It was in existence in 1815.

In 1815 Thomas Wakley was a student of the Borough Hospitals; the greater part of his medical education was acquired at the Grainger School. In 1817 he became a M.R.C.S., and commenced practice. Fortunately, perhaps, he did not altogether succeed, and his great talents were turned in the direction of journalism. He founded the *Lancet* in 1823, with the primary object of disseminating much-needed information hitherto regarded as the exclusive property of members of the London Hospitals, and also with a view of exposing the family intrigues that influenced the appointments in the London hospitals and the medical corporations. For the first ten years of its existence the *Lancet* provoked a succession of fierce encounters between the editor and the members of the privileged class in medicine. In the first number Wakley made a daring departure in commencing a series of shorthand reports of hospital lectures. On December 10, 1824, Mr. Abernethy applied to the Court of Chancery for an injunction to restrain the *Lancet* from publishing his lectures. The injunction was refused by Lord Eldon, on the ground that official lectures in a public place for the public good had no copyright vested in them. He then commenced a regular issue of hospital reports of cases and notable operations. The irritation at them was so great that his exclusion was ordered at St. Thomas's Hospital. He also carried on a campaign against the Royal College of Surgeons. Mr. Wakley and his successors have done work which has advanced the general interest of the profession by leaps and bounds, and during the long period of its usefulness it has always availed itself of the best talent, and many of those who have achieved success in other departments have given their early work to the advancement of medical journalism. At the present time the influence of the press is enormous. The *British Medical Journal*, reflecting the opinions of this Association, shares with the *Lancet* and many other medical periodicals in guiding the profession upon every question to the direct issues constantly occurring.

PHYSICIANS AND SURGEONS OF THE CENTURY.

It is, of course, quite impossible to give anything more than quite a brief enumeration of the brilliant work of the physicians and surgeons of this century, but there are some incidents that deserve notice—take, for instance, the remarkable advance in practical medicine by the physicians of Guy's Hospital. Richard Bright's discoveries in the pathology of kidney disease, which results were published to the world in 1872; Hodgkin, pathologist of the hospital, who published his observations on some morbid appearance of the lymphatic glands and of the spleen; and Thomas Addison who, from 1849 to 1855 was directing attention to the relationship between anemia and disease of the suprarenal capsules. These diseases are now known all over the world as Bright's disease, Hodgkin's disease, and Addison's disease. In 1873 another Guy's physician, Sir William Gull, described to the Clinical Society of London a cretinoid state supervening in adult life in women.

In 1837, Gerhard, a young American physician, clearly laid down the difference of the two diseases of typhus and typhoid fever. After much doubt and discussion the question was finally settled in England by Sir W. Jenner in 1849-50.

The credit of recognizing the connection between the acceleration and violent actions of the heart and the enlargement of the thyroid gland, two of the great cardinal symptoms of exophthalmic goiter, undoubtedly belongs to the great Dublin physician Graves, who in 1835 pointed out in a published lecture that the disturbance of the heart's action is not necessarily associated with organic disease of the heart. Five years later a German physician, Basedow, published a more complete and elaborate account of the clinical features.

Hughes Bennett first described leukocythemia in 1845. A few weeks afterwards Virchow published a case which had been independently observed by him previous to the publication of Bennett's first communication on the subject, and pointed out that the white corpuscle found in the blood were

¹ From advance sheets by courtesy of the *British Medical Journal*.

not pure cells, and termed the disease leukemia. A violent controversy sprang up between those two celebrated men and other supporters. Of this Byrom Bramwell says "that while Bennett was the first to observe and publish a detailed case of the pathologic appearances and blood-changes, Virchow was the first to give an intelligent explanation of the peculiar alteration of the blood which is the essential characteristic of the disease."

Among other great contributions to the advance of scientific medicine, one can but enumerate the works of Marshall Hall, Elliotson, Stokes, Alison, Sir Thomas Watson, the Farris, Sir W. Jenner, Sir J. Simpson, Tyler Smith, the Budds, and Sir James Paget. In connection with the name of Dr. Elliotson, who aroused such a famous controversy in relation to his association with mesmerism, it is interesting to note that he was the first in 1826 to discard the style of dress then prevalent with physicians—namely, knee-breeches and silk stockings. He was also one of the earliest in England to adopt the practice of auscultation.

In surgery, more perhaps than in medicine, the tendency has been to specialize. Some of them inevitable and most desirable, others quite unnecessary. Dentistry is now practised as a special branch of surgery. The earnest work of Sanders, Sir W. Lawrance, and later of Sir W. Bowman, Critchett, and many others, has established ophthalmic practices in this country. In aural surgery, George Pilcher, Toynbee, Yearley, Harvey, Hinton, and many still living have raised aural surgery from a neglected condition to a recognized position as a legitimate branch of surgery.

In all the domains of surgery there has been no more brilliant advance than in abdominal surgery. Operations that scarcely more than forty years ago were deemed unjustifiable—so great was the mortality at that time—are now performed with success in every hospital. For this our thanks are due to Sir Spencer Wells, Keith, Clay, Greig Smith, and many of those still living, but to none more than he to whom all surgery is indebted for antiseptic precautions in treatment.

It is not, perhaps, so generally known as it deserves to be, that William Jeaffreson, of Framlingham, in the County of Suffolk, an East Anglian surgeon, was the first surgeon in England to perform the modern operation of ovariectomy by a small central incision. The circumstances, as recorded in the *Transactions of the Provincial Medical Association of 1837* are as follows: "Mr. Jeaffreson in 1833 lost a patient suffering from an abdominal tumor. She died from tuberculous disease of the lungs, and, obtaining the consent of the friends, he made a postmortem examination, which satisfied him that the tumor could have been removed, and but for the disease of her lungs her life might have been spared."

In November of the same year Jeaffreson and his friend King attended together a lady in her confinement with a small tumor. They subsequently advised an operation, and in May, 1836, a central incision was made, about $1\frac{1}{2}$ inch, the cyst tapped, withdrawn, the pedicle secured by ligature, and the ends cut off short. The wound was adjusted by two sutures, and napkins wrung out in the coldest water were constantly applied to the wound. Sulfate of magnesia was administered every four hours, and all went well until the tenth day, when he was called to his patient at 3 A.M., to find her pulseless, with incessant vomiting and hiccough, with gripping pains in her body. A stimulating enema, with 2 grs. of opium, gave her speedy relief, and she recovered.

His friend and neighbor King, at Saxmundham, Suffolk, about ten miles away, operated a few weeks later, with complete success, his incision being somewhat longer—about 3 inches. Two years subsequently a third East Anglian surgeon, Crisp, of Harleston, who lived about twenty miles from Jeaffreson, who was also successful, with an incision of 2 inches. These three cases, which were performed by three surgeons in general practice in this country, were the first in England, in response to the doctrines of William and John Hunter, and are the more remarkable when we consider that no operation of the kind was attempted in London until four years later, and no ovariectomy was performed in a London hospital until ten years after Jeaffreson's case.

Of another special branch of practice, the treatment of mental affections has greatly improved, and the provision of suitable institutions has generally extended. Among many others to whom we are indebted are William Tuke, 1732-1822, and other members of the same family; Sir E. Bucknill, and many other physicians at home and abroad. A provincial

physician, Dr. Robert Gardner Hill, who was Mayor of Lincoln in 1851, deserves to be specially remembered. In 1839 he published lectures on the management of asylums and the treatment of the insane. He argued that in a properly-constituted building, with a sufficient number of suitable attendants, restraint is never necessary, never justifiable, and always injurious to all cases of lunacy whatever.

Of the further practical results in surgery the results are so well known that it goes without saying that the advance has been enormous, thanks to Sir R. Brodie, Aston Key, Sir W. Lawrance, Robert Liston, Sir James Paget, Syme, and the Edinburgh surgeons Sir W. Ferguson, John Hilton, and the Dublin surgeons, Sir George Humphry and many still living, as well as by the brilliant achievements of surgery in all parts of the world.

The two great discoveries of the nineteenth century in connection with both medicine and surgery are the antiseptic treatment (for which we are indebted to the genius of a living surgeon, Lord Lister), and the use of anesthetics. Those now in general use are nitrous oxid gas, discovered by Sir Humphrey Davy in 1800; of sulphuric ether, by Faraday; and chloroform, by Liebig. I shall not detain you by a history of the introduction of anesthetics into surgical practice, but as we have still living in East Anglia a most distinguished surgeon (Mr. William Cadge), who was present on the occasion of the first operation in London under the influence of ether, I thought it would be interesting to hear his record of the circumstances. Mr. Cadge says: "Robert Liston was the first surgeon in this country to use ether, and those who were present at University College Hospital on December 21, 1846, and witnessed the complete and perfect success of that first venture, will not easily forget the dramatic character of that scene. I was present and assisted at the operation—amputation of the thigh by the double flap method. Some one present timed the operation; it took 30 seconds; the few arteries were tied, and all signs of blood cleared away. A towel was then thrown over the stump, and we watched anxiously for the patient to show that he was not dead; he presently woke up, and when asked once or twice if he could stand the pain of the operation, he accused us of cruelly trifling with his feelings, and when the towel was removed and he saw the naked stump, he burst into tears, and I thought Liston would do the same."

Many fresh fields of inquiry and separate study have been instituted. In 1831 Alfred Swaine Taylor, the famous chemist and medical jurist, was appointed Lecturer on Medical Jurisprudence at Guy's Hospital. His inaugural course was the first delivered in this country, and was attended by many leading counsel and some judges.

In 1842 Parkes was assistant surgeon to the 8th Regiment, when he retired and became physician to University College Hospital. He was the founder and first teacher of military hygiene, and was a great factor in, if not the founder of, the science of modern hygiene.

The elaborate directions in the Mosaic laws for the preservation of health, through scrupulous attention to cleanliness and the isolation of the sick and extreme care in the use of wholesome articles of food and drink, are well known to Biblical students.

The subject has in later years been studied to considerable advantage. In 1801 Heberden wrote: "The cause of so great an alteration in the health of the people of England—for it is not confined to the metropolis—I have no hesitation in attributing to the improvements which have gradually taken place, not only in London but in all the great towns, and in the manner of living throughout the kingdom, particularly in respect to cleanliness and ventilation. Two centuries ago the mortality of London is stated to have been 80 per 1,000; at the present day it is under 20. A century ago ships could barely keep the sea for scurvy, whilst gaols and hospitals were in many cases the hotbeds of fatal disease. Now these conditions are rectified, or at least the means of rectifying them are known."

The special departments which concern the surroundings of man—his personal health, food, drink, clothing, hours of labor, and certain other points, such as the management of infancy, the prevention of disease, the hygiene of the sick chamber, and the disposal of the dead—have been the subjects of legislation during the present century.

State medicine, as an organized department of administration, is entirely of modern growth. The first Act in this

direction was the Towns Improvement Act of 1847; but it was not until the following year, 1848, that a general Public Health Act, embracing the whole of England (except the metropolis), was passed.

The Local Government Board was created in 1871, and finally in 1875 the existing laws were digested into the Public Health Act of 1875 (38 and 39 Vict.).

These Acts were the result of the labor and agitations of many sanitary reformers and associations, such as the Health of Towns Association, the British Association for Improving the Dwellings of the Industrial Classes, which built the first model dwellings.

Such are some of the incidents of the past that have helped to make us what we are. I am deeply sensible of the imperfect and fragmentary sketches I have recorded, but they show, I hope, a record of progress in the physician of today in education, in social status, and in all that goes to make professional life more pleasant. Questions are constantly arising affecting the interests of the profession, and many at this moment require combined as well as personal action. It is the consideration of these matters, in addition to our scientific work, which justifies the existence of the British Medical Association.

In conclusion, may I briefly refer to the growing expense of medical education? It is certainly the most costly of all the learned professions. This is due to the long period of time required for the medical curriculum, and to the multiplication of qualifications, which I regard as a fashionable absurdity. I am not unmindful of the up-to-date requirements of general culture; of an accurate knowledge of anatomy, chemistry, physiology, biology, bacteriology, pathology, physics, optics, mechanics, electricity, and photography, which are all essential to the well-educated physician, they are daily called into requisition in order to diagnose and to direct the eye and hand in the treatment of disease. The necessity for the highest education for this mental training is obvious, and it rests with the General Medical Council to see that this can be obtained without undue restrictions. What I venture to think is wanted is early qualifications, and if the elements of science were more generally taught in school-life that would be easily possible. After obtaining a diploma or license to practice it would be well if the General Medical Council could see their way to institute the requirement of practical experience.

In passing the milestone of life in the year A.D. 1900 I have thought it might be well to take a retrospect of our advance to our present position, and to express the hope that as time goes on our profession may continue to uphold its regard in the estimation and affection of all, and its usefulness may continue unchecked for the advantage of humanity.

Hematomyelia.—Lloyd (*Journal of Nervous and Mental Disease*, February, 1900) reports a case occurring in a negress, 53 years of age, who had fallen down stairs, and immediately was paralyzed. The kneejerks were greatly exaggerated, but there was no ankle-clonus. There was complete paralysis of the bladder and rectum. Sensory disturbances were complete loss of all forms below an irregular line passing around the shoulders just below the clavicles and the spines of the scapulae. Gradually sensation returned, pain being felt in the right leg and left foot, and pain and temperature in the left leg and both arms. There was also recovery of the position sense, and slight tactile sensation in the left foot. A few days later all sensation was again abolished. The patient was very much worse and finally died of pulmonary edema. At the autopsy the cord was macroscopically apparently normal, excepting that in the cervical region there was a small effusion of blood into the central portion. The hemorrhage extended from the fifth to a point above the second cervical segment, and was found chiefly in the anterior portion of the posterior columns. In analyzing this case, it shows that the center of the phrenic nerve was probably involved, although its function was not totally abolished. The sensory symptoms indicate a lesion as high as the third cervical segment. The reflexes, contrary to the usual experience, were increased. In conclusion, Lloyd calls attention to the interesting fact that above the line of sensory disturbance there was hyperidrosis, and below it anidrosis. [J.S.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

The Harrisburg Hospital received during the month of July \$1,090.40 in donations.

The death from cholera of United States Consul, W. Irvin Shaw, of Pennsylvania, at Barranquilla, Colombia, has been reported and afterward denied.

Lost in Alaska.—Dr. J. W. Hickman, formerly of Oxford, Pa., mysteriously disappeared in Alaska some time ago. He was hunting, and is supposed to have fallen into a deep blowhole. For the past 12 years he had practised at Tacoma, Wash.

Catarrhal Conjunctivitis is said to be spreading rapidly throughout Philadelphia and threatens to be almost an epidemic. The cause is said to be the fine dust which blows from the asphalt pavements. With the exception of Washington the disease is said to be more prevalent here than in any other city in the country.

Chemicals in the Milk.—The New Jersey State dairy Dairy Association summoned to Court 17 milkmen charged with selling milk that contained formaldehyd to the North Jersey coast resorts. The milk dealers claim that they are not responsible for the introduction of the chemical into the milk, and say that if the formaldehyd was found in the milk it was placed there at the dairy.

The Christian Scientists.—The refusal of Judge Pennypacker, of Philadelphia, to grant a charter for a church of Christian Scientists here, on the ground that the statute law of Pennsylvania to protect the public from illicit medical practices must be upheld, drew the line of cleavage sharp and clear as a woodman's axe. What we want as a next step is a court that will deal with Christian Science "healers" in the same spirit.—[*Philadelphia Times*]

Vital Statistics of Philadelphia for the week ended August 4, 1900:

Disease.	Cases.	Deaths.
Total mortality		439
Inflammation of appendix 1, bladder 4, brain 15, nerves 1, kidneys 14, heart 1, tonsils 1, lungs 19, peritoneum 4, pleura 2, stomach and bowels 25, spine 2		89
Marasmus 29, debility 4, inanition 21		54
Lungs—tuberculosis of 42, congestion of 1, hemorrhage from 1, edema of 1		46
Cholera infantum 40, morbus 2		12
Heart—disease of 22, fatty degeneration of 2, neuralgia of 1		25
Bright's disease 11, uremia 8, diabetes 1		20
Old age		16
Carcinoma 1, of bladder 1, bowels 1, cecum 1, lips 1, esophagus 1, rectum 1, uterus 1, stomach 5, sarcoma of jaw 1, prostate gland 1, abdominal tumor 1		16
Apoplexy 9, paralysis 4		13
Diphtheria	81	10
Typhoid fever	62	10
Brain—disease of 4, dropsy of 1, congestion of 4		9
Convulsions		8
Pyemia 2, septicemia 4		6
Dysentery 4, diarrhea 2		6
Liver—cirrhosis of 5, disease of 1		6
Casualties		5
Cyanosis		5
Suicide—carbolic acid 3, illuminating gas 1, shooting 1		4
Measles		4
Croup 1, membranous 3		4
Scarlet fever	31	1
Pelvic abscess 1, abortion 1, alcoholism 2, asthma 2, aneurysm of aorta 1, burns and scalds 1, cerebrospinal meningitis 1, pelvic cellulitis 1, drowned 3, dropsy 2, epilepsy 2, erysipelas 1, malaria 1, whooping-cough 1, tetanus 1, tabes mesenterica 2, syphilis 1, stricture of esophagus 1, scrofula 1, rheumatism 1, locomotor ataxia 1, jaundice 2, intussusception 1, hernia 2, hemorrhage from uterus 1, senile gangrene 1.		

Women's Hospital.—The report of the Women's Hospital of Philadelphia, for the month of July, is as follows: Number of patients in hospital July 1, 92; admitted since July 1, 95; discharged, 88; remaining, 89; 1,547 visitors at the clinics, including those of 352 new patients; 2,453 prescriptions filled at the hospital, and 64 operations performed.

Citizens Object to Dredger.—New Jersey's Sewerage Commission received an emphatic protest, August 3, from the citizens of Lyndhurst against a dredger which, under a Government permit, is pumping sand from the Passaic River. "The dredger," said the protest, "is stirring up the bed of the river and disturbing the bed of the river to such an extent that the stench is fearful." A copy of the protest has been sent to the Secretary of War.

The Harrisburg Filter Question.—According to the *Independent* some difference of opinion appears to exist in Harrisburg in regard to the best means of obtaining a pure water-supply. Some are in favor of sand-filtration, while others recommend mechanical or chemical processes. If the water must be taken from a polluted source, filtration is a necessary and, if properly maintained, a salutary process. But experience has taught that if the supply can be brought from a pure source it is safer than to trust to filtration under municipal management. If the city can be supplied with pure mountain water at a cost not exceeding that at which it is now supplied from the Susquehanna why incur the indebtedness of the installation of a filter and its maintenance? It is said that a line of water pipe not over 16 miles in length will bring to Harrisburg a supply of pure soft water sufficient for the needs of 200,000 people.

NEW YORK.

St. John's Guild.—The floating hospitals of St. John's Guild carried in July 31,205 children and mothers, and the seaside hospital gave 9,209 days of treatment.

The Metropolitan Hospital and Dispensary for Women and Children, of New York, has received \$2,000 by the will of the late Dr. Henri Guilbeault of that city.

Elmira Reformatory.—Dr. Frank W. Robertson, formerly of Bellevue Hospital, New York, and for some months senior resident physician of the reformatory, has been appointed acting general superintendent.

Christian Science and Appendicitis.—The County Physician in Newark is investigating the death of Reginald W. Berry, who died of appendicitis, August 1, having refused all medical attendance, and entrusted himself to a Christian Science healer.

Dust from Elevated Cars.—The result of the investigation by the Sanitary Inspector of New York with reference to the cleaning of cars on elevated tracks and rendering life miserable for the residents in the vicinity, is that they are at present cleaned in the railroad yards.

College for Hypnotism.—The American College of Science was incorporated recently at Newark, N. J., with a capital of \$100,000. The incorporators are residents of Rochester. The object of the "college" is "to give instruction in personal magnetism, hypnotism and magnetic healing."

A Prize Essay.—Dr. Adolph Knopf, of New York City, has won the prize of 4,000 marks offered by the Tuberculosis Congress for the best essay on the subject, "How to Fight Tuberculosis as a Disease of the Masses." There were 81 essays offered in competition. The award was made by a committee containing several of the leading German physicians, Count Posadowsky Wehner, and the Duke of Ratibor.

Hospital Against Railway.—The State Railroad Commission in New York, August 2, heard the complaint of the Hudson River State Hospital against the Poughkeepsie and Eastern Railroad Company. The hospital people complain that the freight charges are too high, and that it costs more to get goods from Poughkeepsie to the Hospital than it does in Poughkeepsie to get goods from New York. The chairman indicated that the decision would favor the railroad.

Physician Fined for Fast Driving in Automobile.—Dr. Wallace C. Clark, of New York, was arrested July 30, while answering an emergency call in his automobile. He was fined \$3.00 by the magistrate, who said the law did not allow him to discriminate in favor of physicians.

A Human Ostrich.—With the x-rays, the tenpenny nails and bone checks which Josn Tasel swallowed for 55 cents in a Brooklyn saloon recently have been located. Tasel is now in the Eastern District Hospital, Brooklyn, and as soon as his condition is such that an operation can be performed the nails will be removed.

The Röntgen Society of the United States will meet in New York December 13 and 14, 1900, at the Academy of Medicine. Papers have been promised by eminent men abroad and in the United States, and a successful meeting is apparently assured. There will be offered advantages to the visiting members for instruction in x-ray work that cannot be had under any other conditions.

Tuberculosis Experiments.—The Tuberculosis Committee of the State Board of Health of New York is at present conducting experiments with the milk of a tuberculous cow. This milk is being fed to rabbits, which are also inoculated with it. Besides the rabbits, some guineapigs will be inoculated with the milk, and also with the human tubercle-bacilli, and the result carefully noted.

Albany Medical College.—Dr. Clarkson C. Schuyler, A. M. C., '75, offers a yearly prize of \$100, to be awarded at the annual meeting of the Alumni Association, for the best essay written by a graduate of this college on some prescribed subject. The subject for next year is: "The Influence of the Discovery of the Relation of Bacteria to Disease on the Practice of Medicine Exclusive of Surgery."

Lives with a Broken Neck.—Although the first cervical vertebra and the base of the skull are broken, physicians believe the life of Philip Scheuerman of Fayetteville, N. Y., can be saved. His body is paralyzed, but he is able to take nourishment and retain it. The upper portion of his body, including the neck and head, was placed in a plaster cast, leaving only the face exposed. Tension straps were adjusted to relieve the spinal cord of pressure. The case is similar to the Duryea case in New York, previously mentioned in these columns, in which the fifth cervical vertebra was broken. Walter B. Duryea is at Dansville and is slowly but surely improving in general health.

NEW ENGLAND.

Boston's Cold-Water Fountains.—An appropriation of \$3,000 has recently been made in Boston to buy ice for 30 free cold-water fountains, established in various parts of the town.

Physician Nominated for Governor.—At a meeting of the State Democratic Convention held at Concord, N. H., August 1, Dr. Frederick E. Potter, of Portsmouth, was nominated for Governor.

Patrol Wagons as Ambulances.—According to the *Boston Medical and Surgical Journal* a decided improvement has recently been made in the police service of Boston, by converting patrol wagons into auxiliary ambulances. The wagons are now provided with rubber tires, and the seat so arranged that room may be made for a stretcher if necessary. It is said that new wagons which from this time on shall be added to the department will have dropped axles similar to those on ambulances. At one of the police stations an emergency room, properly equipped, has been fitted up, an example which might well be generally followed. Particularly during the excessive heat of summer are such added conveniences desirable.

CHICAGO AND WESTERN STATES.

Chicago's Drinking-Water.—The recent heavy rains failed to pollute the drinking-water of Chicago. This is due to the current created from the lake by the drainage canal. The only pollution from which the water-supply can now suffer will be caused by the sewage of Evanston and other northern suburbs.

Dr. Harry F. Kneeder, of St. Louis, Major in the Medical Department of the U. S. Army, will sail for China August 16. :

Faith-Healers Driven from Mansfield.—On July 31, 4 faith-healers were driven from Mansfield, O., by a howling mob. Two had been previously decorated with blue paint.

Rubbish in Chicago River.—In spite of repeated warnings the wholesale houses along the Chicago river persist in polluting its waters. Orders have been issued by the Harbor Engineer to arrest these parties if the practice is not discontinued.

Isolation Hospital of Chicago.—One case of smallpox remains in the isolation hospital, Chicago, and the patient will leave soon. Then the hospital will be vacant for the first time since October. In June there were 16 cases at the hospital, the largest number in the institution at any one time since the disease became epidemic last fall.

Impure Milk.—Formaldehyd poisoning is said to be the cause of the death of 3 children in the Indianapolis Orphan Asylum. The chemist noted the presence of the poison in the samples of milk secured at the institution. Physicians say that as a rule a preservative of some kind is being used in the city, and investigations are being made to ascertain just what it is.

Smallpox in California.—In all, 62 cases of smallpox have been reported in California with two deaths. The disease is now under control. Dr. H. H. Look, who was commissioned by the State Board of Health to visit the districts where smallpox had broken out, has fulfilled his mission and now declares that there is immediate necessity for a number of the smaller towns in the State to give attention to the matter of better sanitation.

Cavalry Horses Have Glanders.—Glanders has broken out among the horses at the Presidio, San Francisco. There are about 1,200 horses at the Presidio stables belonging to the various cavalry regiments and awaiting shipment to China on the horse transports. As soon as the presence of glanders was discovered, 8 infected animals were shot. The commanding officer has received orders to spare no efforts or expense in stamping out the disease before it can become epidemic.

Is the Garbage Crematory a Menace to Health ?—This is the question to be decided by a Master in Chancery in Chicago. Employees of the crematory testify that the odors are sweet and healthful, while the residents in its vicinity testify that the stench is terrible. Charles B. Gibson, chemical expert, and Professor Haines, of Rush Medical College, said that it might be harmful in 3 ways: first through the direct deleterious action of gases on the human body, second by producing nausea, and third by the nervous shock due to the effect of the stench on the olfactory nerves.

Poisonous Bugs In Mushrooms.—At Harvey, Ill., recently, three members of a family died, supposedly from eating toadstools, but it was shown that they had eaten mushrooms of the finest quality. A mushroom expert testified that in his opinion the poisoning was caused by a small black bug which, he said, he had found recently making its home in the top of mushrooms. Men well versed in entomology said they had heard of such a bug in South America which makes its home in certain plants and causes the death of any animal which eats the foliage. None of them had heard of the insect in this country.

SOUTHERN STATES.

New Orleans Marine Hospital.—Dr. C. P. Wertebaker, of the United States Marine-Hospital Service, assumed command at the New Orleans Marine Hospital, August 4.

Discharge of Physician Causes Strike.—At Clarksburg, W. Va., August 2, 300 miners went on a strike because the company has discharged the physician whom the miners pay for at \$1.00 a month each, and substituted a stranger of the company's own selection.

Yellow Fever at Tampa.—Two cases of yellow fever are reported at Tampa and the infection is said to be general. Quarantine restrictions are placed on the city until the arrival of the State Health Officer of Florida.

Lightning Causes Paralysis.—While Dr. H. R. Brightbell, of Saxton, Md., was driving July 28, lightning struck a tree at the roadside. He was rendered unconscious and is now in a serious condition from paralysis, the result of the shock.

Women Petition City Council.—The ladies of Salisbury, Md., have requested the City Council to put on a garbage-cart and suppress the hog-pen nuisance. They also demand punishment of the men who expectorate on the pavements of Salisbury.

Physicians Nominated in Delaware.—At a meeting of the Union Republican party of Delaware, held at Dover, August 6, Dr. George W. Marshall, of Milford, was nominated for governor, and Dr. Caleb R. Layton, of Sussex County, for the long term in Congress.

Quarantine Against Central America.—The Louisiana Board of Health on August 2 proclaimed a quarantine of 5 days against all fruit vessels from Central America carrying passengers. A few days ago the Board quarantined against Costa Rica, because of the appearance of yellow fever at Port Limon.

Resignation of Dr. Burch Accepted.—Dr. W. B. Burch, one of the police surgeons of Baltimore, resigned because the Board of Police Examiners refused to recede from its position requiring physical examination of applicants for appointment on the force to be made before the mental examination by the Examiners.

State Law to be Enforced.—Dr. Samuel T. Haffner, health officer for Frederick County, Md., acting under the advice of the State Board of Health, has appointed subregistrars in the various election districts of Frederick County, in order to enforce the law passed by the last legislature in regard to the registration of deaths and births.

Taxing Charities.—The Board of Estimates of Baltimore recently decided to grant no favors to charitable or religious institutions in the matter of permits for minor privileges. As a result there is some dissatisfaction about the price fixed by the Board for permits enabling the Baltimore Orphan Asylum to lay a drain to connect with the city sewer.

District Health Officer Appointed.—Dr. W. C. Woodward has again been appointed health officer of the District of Columbia, the Commissioners have suspended the order issued by the board in 1894, which limited the term of that office to 3 years. In suspending this order the health officer is placed on the same level with the majority of other District officials.

An Epileptic Asylum.—The Special Building Board, appointed by the last legislature of Texas, to decide upon the plans and specifications for the building of the Epileptic Asylum at Abilene, Tex., met July 31 and passed on the plans, and the work of erecting the buildings for the institution will be pushed as rapidly as possible. An appropriation of \$50,000 has been made.

Surgeons Reappointed.—On August 3, Drs. W. Thompson Burch and Frank P. Vale were reappointed members of the Board of Police and Fire Surgeons by the Commissioners of the District of Columbia and in doing so they made the term of office of the surgeons to continue at the pleasure of the Board of Commissioners. The next appointment of consequence is that of Coroner.

Quarantine Against Tampa.—State Health Officer Blunt has instructed the quarantine stations at Galveston and Sabine Pass to place in quarantine all ships entering those ports from Tampa, owing to the presence of yellow fever there. The quarantine will be established on all the rail lines between there and New Orleans if necessary, but for the present the Galveston and Sabine Pass quarantines are considered sufficient.

To Prevent Filthy Gutters.—At the request of Health Commissioner Bosley, Baltimore's policemen are instructed to report filthy or obstructed gutters to the Health Department.

Municipal Hospital Site.—The District of Columbia Commissioners have received, in response to their advertisement for bids for a site for the new Municipal Hospital, offers from more than 50 property holders. The prices ranged from \$175 to \$16,000 an acre. The sum of \$100,000 was appropriated for this purpose by Congress.

MISCELLANY.

India Famine Relief Fund.—John Crosby Brown, treasurer of the Committee of 100 on India Famine Relief, reports that subscriptions up to the present time aggregate \$194,268.66.

Meats for Soldiers in the Orient.—Chicago packers were asked by the United States Government to furnish 2,000,000 pounds of meats within 30 days for the American soldiers in the Orient. This is said to be the largest requisition ever issued by the Government.

Serum-Treatment of Yellow Fever.—Advices from Vera Cruz show that Dr. Bellinzaghi's experiments with yellow fever patients continue to show remarkable results. All new patients treated with the serum are improving, and the black vomit has been stopped.

Famine as a Chinese Factor.—It is said by prominent Chinamen that famine has much to do with the Boxer uprising, and that it is largely the battle of the poor, who have nothing and are starving, against the rich. The hostility to the native Christians is on account of their receiving from the missionaries food and aid, while there is nobody to give to the Chinaman who is not Christianized.

Quarantine Stations in Alaska.—As there is no local quarantine at Cape Nome or Dutch Harbor, Alaska, national quarantine stations have been established for these two ports by the Surgeon-General of the Marine-Hospital Service with regard to incoming vessels. For vessels, cargo or persons leaving these ports for other ports and places in the United States the interstate quarantine regulations will be enforced.

For Segregation of Lepers.—General MacArthur has convened a board consisting of Major Lewis M. Maus, surgeon; Captain George P. Ahren and Captain W. E. Horton, to select an island in the archipelago for the segregation of lepers, to prepare plans and estimates for suitable buildings thereon and estimates of salaries for the necessary officials and employes. The board is also charged with fixing the ration and other allowances for the support of such leper colony. This action was taken in view of the large number of people in the Philippines afflicted with leprosy, who are reported as a menace to public health.

Hospital-Ship "Solace" Sails from Taku to America.—The following telegram has been received: *Solace*, with sick and wounded, proceeded Nagasaki, Yokohama, Guam, Honolulu, and Mare Island; 5 marines and navy officers, 5 army officers, 9 navy men, 19 marines, 65 Ninth Infantry. All men will remain aboard *Solace* unless otherwise recommended by army medical authorities at Nagasaki. Army hospital relief ship *Relief* preparing at Nagasaki for Taku. Japanese hospital ship alternating here at our disposal, if needed. Lieutenant Leonard's condition more favorable; recovery hopeful.

Duration of Life in Various Employments.—From the following statistics given in the *Medical Record* it will appear that average longevity apparently has little to do with employment which is not in itself dangerous. Of the poets, 46 averaged 66 years; 39 painters and sculptors, 66 years; 30 musicians, 62 years; 26 novelists, 63 years; 40 men of letters, 67 years; 22 religious, 66 years; 35 women, 69 years; 18 philosophers, 65 years; 39 historians, 65 years; 53 scientists and inventors 72 years; 14 agitators, 69 years; 48 commanders, 71 years; 112 statesmen, 71 years. A general summary shows that the average duration of life has been about 68 years and 8 months.

Obituary.—CURTIN M. C. ENGLAR, of Baltimore, July 30, aged 27 years.—E. M. ROSENCRAZ, of Chicago, July 30, aged 61 years.—JAMES D. GRAY, of Philadelphia, July 31, aged 42 years.—E. W. NORTON, of New Cambria, Mo., July 31, aged 70 years.—J. M. JEFFRIES, of Albermarle County, Va.—W. C. LENCE, of Jonesboro, Ill., August 1, aged 55 years.—ELISHA CHENERY, of Boston, August 1, aged 71 years.—F. W. HULSBY, of New Haven, Conn., in Luzon, August 1.—R. H. WHITE, of Pine Bluff, Ark., August 4, aged 51 years.—I. S. MOORE, of Northwood, Ia., August 2.—DAVID S. MILLS, of Pine Bluff, Ark., August 3, aged 71 years.—A. T. HARRIS, of San Francisco, July 26.—P. S. POSTELL, of Iberville, La., August 3.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended August 4, 1900:

Yellow Fever in Havana.—Surgeon Carter, of the United States Marine-Hospital Service, says there has been a steady and fairly rapid increase in the number of yellow fever cases reported in Havana. He says that no one who has had any experience is willing to make a very definite prognosis as to the spread of yellow fever, especially where those susceptible to the disease form so small a proportion. It seems probable that this season will be one of average severity. On account of yellow fever at the Havana naval station, the Secretary of the Navy has directed that all the marines who can be spared from that station be returned to the United States, although only 35 cases are officially reported in Havana and the mortality from the disease is said to be very low.

Surgeons Assigned to Duty.—Major H. E. Kilbourne, surgeon, has been ordered to Newport News, to make a sanitary inspection of the transport *Buford*, refitting at that place. The following assistant surgeons have been ordered to San Francisco for assignment to duty with troops going on foreign service: Lieven de Poorter, at Cuba; A. W. Dumm, at Columbus, Ohio; J. W. Holland, at Westfield, Mass.; Thomas J. Strong, at Burlington, Vt., and C. C. Whitcomb, at Camden, Me.; Patrick McGrath, at Washington, D. C.; D. W. Overton, at New York City; John Pinquard, at Vinila, I. T.; E. F. Slater, at New York City; J. W. Thornton, at Ayreshire, O.; G. M. Van Poole, Salisbury, N. C.; Vernon J. Hooper on the transport *Sedgwick*, and C. B. Mittelstaedt and E. C. Schultze at New York City.

Changes in the Medical Corps of the U. S. Army for the week ended August 4, 1900:

NOUEL, AUGUSTE A., acting assistant surgeon, is assigned for duty to Pinar del Rio Barracks.

STEPHENSON, Major WILLIAM, surgeon, will proceed on the Army transport "Sumner," via Nagasaki, Japan, direct to Tuku, China, and report to Brigadier-General Adna R. Chaffee for assignment to duty.

ZAUNER, ROBERT H., acting assistant surgeon, will proceed to his home at Washington, D. C., where he will report by letter to the Surgeon-General of the Army, for annulment of contract.

VAN METER, B. F., acting assistant surgeon, will proceed to his home at Lexington, Ky., where he will report by letter to the Surgeon-General of the Army, for annulment of contract.

READ, W. P., acting assistant surgeon, will proceed to his home at Philadelphia, where he will report by letter to the Surgeon-General of the Army, for annulment of contract.

MITTELSTAEDT, CHARLES B., will proceed to his home in New York City, where he will report by letter to the Surgeon-General of the Army for annulment of contract.

CURRY, JOSEPH J., acting assistant surgeon, is assigned to temporary duty at the U. S. General Hospital, Presidio, awaiting transportation to the Philippine Islands.

BROWN, Major IRA C., surgeon, is granted leave for 1 month, with permission to apply for an extension of 1 month.

STONE, First Lieutenant J. HAMILTON, assistant surgeon, is relieved from duty at Santa Clara Barracks and will proceed from Santa Clara to Matanzas, Cuba, for duty.

BROWN, WILMOT E., acting assistant surgeon, will proceed to Fort Huachuca for duty with troops of the Ninth Cavalry, en route to the Philippine Islands.

NAOLE, JOHN S., acting assistant surgeon, now in St. Paul, Minn., will proceed to Seattle, Wash., and report to the commanding officer First Cavalry, for duty with the troops of that regiment en route for the Philippine Islands.

WALL, FRANCIS M., acting assistant surgeon, will proceed to Wilcox, Ariz., and upon arrival there of troops from Fort Grant, will report to the commanding officer for duty with that command, en route to the Philippine Islands.

STOEKLE, CHARLES H., acting assistant surgeon, will proceed to Holbrook, Ariz., and upon arrival there of troops from Fort Apache, will report to the commanding officer for duty with that command en route to the Philippine Islands.

OWEN, Major WILLIAM O., surgeon, is granted leave for 1 month, to take effect when his services can be spared.

GRUBBS, ROBERT B., acting assistant surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

CORBUSIER, Major WILLIAM A., surgeon, is granted leave for 2 months.

WILLIAMSON, First Lieutenant LLEWELLYN P., assistant surgeon, is relieved from further duty in the department of Western Cuba, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to China.

USHER, First Lieutenant FRANCIS M. C., assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to China.

HAYWARD, EDWIN P., acting assistant surgeon, is relieved from duty

at the General Hospital, Presidio, and will report to the commanding general, department of California, for assignment to duty with troops en route to China.

DEAN, GUY S., acting assistant surgeon, will proceed from Kenton, Ohio, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to the division of the Philippines.

GRIFFIS, FRANK C., acting assistant surgeon, will proceed from Mt. Gilead, Ohio, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to the division of the Philippines.

ROBERTS, WILLIAM M., acting assistant surgeon, will proceed from Baltimore, Md., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to the division of the Philippines.

TEFFT, WILLIAM H., acting assistant surgeon, will proceed from Belmont, N. Y., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route for the division of the Philippines.

WOODHULL, Lieutenant-Colonel ALFRED A., is granted leave for 8 days from July 20.

KILBOURNE, Major HENRY S., surgeon, medical superintendent, army transport service, will proceed to Newport News, Va., for the purpose of making a sanitary inspection of the transport "Buford," now refitting at that place.

CURRY, JOSEPH J., acting assistant surgeon, granted leave for one month.

POORTER, LIEVEN DE, acting assistant surgeon, granted leave for 15 days from July 30.

POORTER, LIEVEN DE, acting assistant surgeon, is relieved from further duty in the division of Cuba upon the expiration of the leave granted him, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops going on foreign service.

DUMM, ALBERT W., acting assistant surgeon, will proceed from Columbus, O., to San Francisco, Cal., and report to the commanding general, department of Cal., for assignment to duty with troops en route to the division of the Philippines.

HOLLAND, JAMES W., acting assistant surgeon, will proceed from Westfield, Mass., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to the division of the Philippines.

STRONG, THOMAS J., acting assistant surgeon, will proceed from Burlington, Vt., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to the division of the Philippines.

WHITCOMB, CLEMENT C., acting assistant surgeon, will proceed from Camden, Me., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to the division of the Philippines.

HARVEY, Major PHILIP E., surgeon, leave is extended 7 days.

GIBSON, Major ROBERT J., surgeon, now on leave, will proceed to Washington, D. C., and report to the Surgeon-General of the Army for further instructions.

CORBUSIER, Major WM. H., surgeon, upon expiration of the leave granted him, July 27, will proceed to Fort Columbus for duty.

WINN, Major WM. B., is relieved from further duty in the department of Western Cuba, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

BAKER, First Lieutenant DAVID, assistant surgeon, is relieved from further duty in the department of Western Cuba, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

LAWRENCE, W. P., acting assistant surgeon, is granted leave for 1 month.

SHELBY, W. D., acting assistant surgeon, is granted leave for one month.

ALEXANDER, JAMES A., acting assistant surgeon, is relieved from duty in the division of Cuba, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

ESCOBAR, JULIUS A., acting assistant surgeon, is relieved from duty in the division of Cuba, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

McLAUGHLIN, WHARTON B., acting assistant surgeon, is relieved from duty in the division of Cuba, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

JACKSON, THOMAS W., acting assistant surgeon, is granted leave for 15 days, with permission to apply for an extension of 15 days and permission to go beyond sea.

DAVIS, OSCAR F., acting assistant surgeon, will proceed from Bloomington, Ind., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

FEENEY, JOHN M., acting assistant surgeon, will proceed from Huntsville, Ala., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

HELLER, JOSEPH M., acting assistant surgeon, now in Washington,

D. C., will proceed to Fort Columbus for duty, to relieve Acting Assistant Surgeon W. Edson Apple.

BROWER, THOMAS E., hospital steward, now on furlough at Fort Columbus, is relieved from further duty in the department of Puerto Rico, and will report for temporary duty at Fort Columbus.

BAOWN, Major IRA C., surgeon, is relieve from duty at present station and will report on the transport "Hancock," scheduled to leave June 15 to San Francisco, Cal., for duty thereon while en route, reporting for duty to the commanding general, department of California, for instructions to return to the Philippines.

CURRY, JOSEPH J., acting assistant surgeon, is relieved from duty at present station, and will report on the transport "Hancock," scheduled to leave June 15, to San Francisco, Cal., for duty thereon while en route, reporting to the commanding general, department of California, for instructions to return to the Philippines.

READ, WM. P., acting assistant surgeon, is relieved from duty at present station, and will report on the transport "Hancock," scheduled to leave June 15, to San Francisco, Cal., for duty thereon while en route, reporting to the commanding general, department of California, for annulment of contract.

VAN METER, BENJAMIN F., acting assistant surgeon, is relieved from duty at present station, and will report on the transport "Hancock," scheduled to leave June 15, to San Francisco, Cal., for duty thereon while en route, reporting to the commanding general, department of California, for annulment of contract.

ZAUNER, ROBERT H., acting assistant surgeon, is relieved from duty at present station, and will report on the transport "Hancock," for duty thereon while en route, reporting to the commanding general, department of California, for annulment of contract.

MITTELSTAEDT, CHARLES B., acting assistant surgeon, is relieved from duty at present station, and will report on the transport "Hancock," scheduled to leave June 15, to San Francisco, for duty thereon while en route, reporting to the commanding general, department of California, for annulment of contract.

PENROSE, Major GEORGE H., surgeon, is granted leave for 1 month on surgeon's certificate, with permission to visit Japan.

TURRILL, Major HENRY S., surgeon, will proceed to Ololo Panay, reporting to the commanding general, department of the Visayas, for duty as chief surgeon of that department, relieving Major Louis W. Crampton, surgeon, who will proceed to Manila for instructions.

BANISTER, Major WILLIAM B., surgeon, is relieved from duty at his present station and will report to the commanding officer, Ninth Infantry, at the Exposition Barracks, Malate, Manila, P. I., for duty with that regiment on the expedition to Taku, China.

MARROW, First Lieutenant CHARLES E., assistant surgeon, is relieved from duty at his present station and will report to the commanding officer, Ninth Infantry, at the Exposition Barracks, Malate, Manila, P. I., for duty with that regiment on the expedition to Taku, China.

CALHOUN, WILLIAM W., assistant surgeon, is relieved from duty at his present station and will report to the commanding officer, Ninth Infantry, at the Exposition Barracks, Malate, Manila, P. I., for duty with that regiment on the expedition to Taku, China.

BARNEY, FRED. M., assistant surgeon, is relieved from duty at his present station and will report to the commanding officer, Ninth Infantry, at the Exposition Barracks, Malate, Manila, P. I., for duty with that regiment on the expedition to Taku, China.

IVES, Major FRANCIS J., surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to China.

CARTER, HENRY R., Jr., acting assistant surgeon, now at Vancouver Barracks, is assigned to duty temporarily at that place.

TATAX, J. P., acting assistant surgeon, is granted leave for 2 months.

HOOPER, VERNON J., acting assistant surgeon, now at New York City, is relieved from further duty on the transport "Sedgwick" and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

MCGAATH, PATRICK, acting assistant surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

OVEATON, DAVID W., acting assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

PINQUARD, JOSEPH, acting assistant surgeon, will proceed from Vineta, Ind. Ter., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

SLATER, ERNEST F., acting assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

THORNTON, JAMES W., acting assistant surgeon, will proceed from Ayrshire, Iowa, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

VAN POOLE, GIDEON M., acting assistant surgeon, will proceed from Salisbury, N. C., to San Francisco, Cal., and report to the com-

manding general, department of California, for assignment to duty with troops destined for foreign service.

MITTELSTAEDT, CHARLES B., acting assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to China.

SCHULTZE, ERNEST C., acting assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to China.

O'REILLY, Lieutenant-Colonel ROBERT M., deputy surgeon, is relieved from the command of Josiah Simpson U. S. General Hospital Fort Monroe, and will turn over the quartermaster's property for which he is responsible to Major Wm. J. White, quartermaster, and dispose of the property of the medical department under instructions from the Surgeon-General of the Army.

The following changes in the stations and duties of officers are ordered: Major ROBERT J. GIBSON, surgeon, is relieved from further temporary duty at San Francisco, Cal., and will proceed to that city and report to the commanding general, department of California, for assignment to duty as attending surgeon and medical superintendent of the Army transport service in that city, to relieve Major WILLIAM H. ARTHUR, surgeon. Major Arthur will proceed to Taku, China, and report to Major-General Adna R. Chaffee, commanding the United States forces in China, for assignment to duty.

Changes in the Medical Corps of the U. S. Navy, for the week ended August 4, 1900:

WOODS, G. F., medical director, detached from the Naval Hospital, New York, August 18, and ordered home and to wait orders.

BASIN, H. J., medical director, ordered to duty in charge of the naval hospital, New York, August 18.

VOX WEDEKIND, L. L., passed assistant surgeon, detached from the "Indiana," and ordered to the naval hospital, Chelsea, Mass., for treatment.

ELMER, N. E., assistant surgeon, ordered to the Boston Navy Yard, August 1.

GORDON, F. T., pharmacist, warranted pharmacist from July 28, 1900.

RICHARDS, T. W., passed assistant surgeon, detached from the "Natchias," when put out of commission, and ordered to the "Indiana."

DELANCY, C. N., assistant surgeon, ordered to additional duty at the naval hospital, Newport, R. I.

STUART, A., assistant surgeon, detached from the "Yankton" and ordered to temporary duty on the tug "Fortune" at the New York Navy Yard. August 4.

Changes in the U. S. Marine-Hospital Service, for the week ended August 2, 1900:

WHITE, J. H., surgeon, to proceed to Mullet Key Detention Camp, Florida, as inspector. July 27.

WILLIAMS, L. L., surgeon, to proceed to Stapleton, N. Y., as inspector of unseizable property. July 31.

SMITH, A. C., passed assistant surgeon, leave of absence granted by Bureau letter of June 30, revoked July 27.

WICKES, H. W., passed assistant surgeon, Bureau letter of June 26, granting leave of absence for 15 day, amended so that said leave shall be for 4 days only. August 1.

GREENE, J. B., passed assistant surgeon, granted leave of absence for 23 days. August 1.

MATHEWSON, H. S., assistant surgeon, granted leave of absence for 1 month from September 5. August 1.

WALKLEY, W. S., acting assistant surgeon, granted leave of absence for 2 days. August 2.

RYDER, L. W., hospital steward, granted leave of absence for 15 days from August 1. July 30.

Tuberculous Infection.—Edward R. Baldwin (*Yale Medical Journal*, March, 1900) discusses the means of infection by tubercle-bacilli, and how the dangers may be lessened. Direct transmission of the germ from mother to fetus has been conclusively shown, but is believed to be rare. The germ cannot develop except in susceptible soil,—this is transmitted. About one-half of all persons afflicted with tuberculosis have tuberculous relatives. Long exposure, such as living with persons afflicted with tuberculosis, appears to be responsible for fewer infections than is commonly thought,—especially when the ordinary precautions are taken. The most common means for conveying the germ are handkerchiefs, sputum, soiled hands, beard, and moustache, contamination of food by coughing. But the germ appears to be ubiquitous, and the proper treatment looks to the proper power of resistance of the individual. Spitting in public places should be prohibited. Mouth-breathing should be corrected. Handkerchiefs should be made of cheap material, never washed, but destroyed. [M.B.T.]

Foreign News and Notes.

GREAT BRITAIN.

Bristol Lunatic Asylum.—The new wing of the Bristol Lunatic Asylum is now completed. It consists of 4 wards, which will provide accommodation for 150 female patients, and also rooms for the nursing staff. A small hospital for infectious diseases, fitted with 6 beds, 3 for each sex, has also been added. The institution will now afford accommodations for about 1,000 patients. The estimated cost of the new building is £45,000.

University of Birmingham.—Sir James Chance has given £50,000 to the endowment fund. Lord Calthorpe and his son gave land which is valued at £20,000. The new university has been fortunate in the friendship of those who have made large donations. Mr. Andrew Carnegie gave £50,000, and an anonymous donor a similar sum. The total amount promised in land and money reaches about £400,000, of which amount one-half has been furnished by six donors.

Plague in London.—The Marine Hospital Service has received the following dispatch from Past Assistant Surgeon Thomas: "There have been 4 cases of plague and two deaths from plague in London. Diagnosis confirmed by bacteriologic examination." Health Officer A. H. Doty, of New York, received the following cable from Dr. Murphy, of the City Council, at London, in relation to the existence of bubonic plague: "None in London. Two occurred last in native crew from East, in hospital mouth of Thames."

Results of Antityphoid Inoculation.—The Director-General of the Army Medical Department is reported to have stated that the results of inoculation for typhoid fever, while it afforded some protection against contracting the disease, rather increased the risk of death when contracted, but that this only applied to the men, as both the incidence and case mortality among officers appeared to be increased by inoculation. Recent statistics of Professor Wright, of Netley, show that both attacks and deaths from typhoid fever were 7 times less in the inoculated than in the uninoculated. It is not known whether this applied equally to officers and men separately.

The Extinction of Rabies.—It appears that the Board of Agriculture, of Manchester, has now no muzzling orders in force. In 1895 as many as 672 cases of rabies were reported, but they have gradually decreased till last year when there were 9. The county of Lancaster suffered specially, having nearly a fifth of the total number of outbreaks. There were only 5 cases in 1898 and none since, so that we may hope to have done with the disease unless there is reimportation. The restrictions as to the movements of dogs into and out of the country seem, in some cases, unnecessary, but it is as well to err on the side of caution and safety even at the cost of occasional private inconvenience and annoyance.

The Cork and Kerry District Lunatic Asylums.—In the Cork Asylum there are 1,496 inmates, which is 239 over the standard limit; while in the Killarney Asylum there is still a small margin of accommodation available, as the number of patients was 526 and the number for which there is accommodation is 683. In his report the resident medical superintendent of the Cork Asylum makes the following instructive observations on the causes of insanity: "A further explanation for the steady increase in numbers must, I think, be set down to heredity. In many of my annual reports for the past 25 years I have laid stress on this fact, but some things cannot be said too often, and as the composition of asylum boards has within the last year so materially changed I think no harm can be done by again referring to the matter. Emigration tends to remove the fittest, those best able to withstand the battle of life, from our midst, leaving at home the delicate, the neurotic, and many liable to transmit to posterity the seeds of disease; the result is that at least 35% of cases of insanity in this country are directly traceable to heredity."—[*Lancet*.]

Belper Isolation Hospital.—At a meeting of the committee of the Belper Union Isolation Hospital representative of the contributing districts, some very extraordinary statements were made with regard to the management. The hospital was opened for the reception of patients in March, 1899. It is stated that the medical superintendent resigned in November and that the new superintendent then appointed resigned after a short period. Another medical superintendent was then appointed, and the meeting to which we have referred had before it a letter from him making various complaints as to the general administration of the hospital by the matron; among other allegations made by him is that a dress worn by the housemaid was sent by the matron to be repaired by a convalescent patient, and that the dress was given back to the housemaid without disinfection, and that at the time the letter was written this girl had come under treatment for the disease. Letters of complaint were also read from nurses employed in the hospital, one of whom stated that she had to employ a ball syringe for giving nutrient enemata for syringing the throat also. Medical men will recognize that these statements are of a serious character, and will hope that the matron will be able to give some satisfactory explanations at the adjourned meeting of the committee.

Centenary of the Royal College of Surgeons of England.—The proceedings in connection with the Centenary Festival of the Royal College of Surgeons of England began July 25. Prof. C. Stewart gave demonstrations to the Fellows, members and guests in the museum of the college, and at the same hour Dr. T. G. Brodie gave lantern demonstrations at Examination Hall, in illustration of the work done under his supervision as director of the laboratories of the Conjoint Board. The August Council meeting of the college was held in the afternoon, the president, Sir William MacCormac being in the chair. Dr. Frederic Shepherd Dennis was introduced and after signing the by-laws and making the required declaration was admitted a Fellow of the College. The president stated that the vacancy in the Board of Examiners in Dental Surgery caused by the death of Mr. Storer Bennett, July 19, would be filled up at the quarterly Council meeting in October. The Council appointed Mr. H. G. Howse and Mr. A. Pearce Gould to represent the college on the Senate. Professor Pachoutine, president of the Imperial Military Academy of Medicine of St. Petersburg, presented to the Council an address of congratulation on the centenary of the College. Addresses of congratulations were also received from Professor Sklifosovsky on behalf of the Imperial Clinical Institute of the Grand Duchess Helena Pavlovna, from the Royal College of Physicians of London, and from the Royal Institute of Public Health. In the evening a conversation was held at the College when the English surgical and scientific world was well represented. On the morning of July 26, Professor Stewart and Dr. Brodie continued their work of demonstrating and in the afternoon Sir William MacCormac delivered the address of welcome. Among other things he said that "a knowledge of the history of our art and science tends to make us juster judges both of our own work and that of others. When we search the history of the development of scientific truth we learn that no new fact or achievement ever stands by itself, no new discovery ever leaps forth in perfect panoply as did Minerva, from the brow of Jove. Absolute originality does not exist, and a new discovery is largely the product of what has gone before. Again and again we may read in words of some half-forgotten worthy the outlines of an idea which has shown forth in later days as an acknowledged truth. We see numerous instances of this in the history of surgery. Some fellow-worker in years long past has discovered a new fact or indicated the path leading to a fresh truth. It is forgotten, and a century later something nearly the same, or mayhap a little better, is discovered afresh. The psychologic moment has arrived, and the discoverer reaps the reward not only of his own labors but of those of his predecessors as well. The countless trials and experiments which ended in the general use of ether and chloroform in surgery—that trebly blessed discovery of a sure relief from pain—were guided by the experience of previous trials, half successful, half failures. Science knows no narrow national boundary. It is the common property of us all. We desire to sympathize with our fellow-workers

abroad and to appreciate their work, as we trust and believe that they appreciate ours. In this address I have ventured to urge that we are much beholden to those who have gone before. In but a few years all who are now present will also belong to the past. Let us hope that, as we have not altogether forgotten those who preceded us, we, too, may be remembered a little by those who are to follow."

CONTINENTAL EUROPE.

Canned Meat for Troops.—Consul Pitcairn, at Hamburg, Germany, writes as follows to the State Department: "The Government authorities at Kiel are compelled to buy canned meats whose import was to be excluded on account of alleged impurities dangerous to the health of consumers, at a high price in foreign countries, because of the inability of Germany to supply home demands. In consequence of this exclusion the provisioning of troops for China has been greatly interfered with."

Light-Therapy in Russia.—The Dowager Empress of Russia, who, like her sister the Princess of Wales, takes the greatest interest in Professor Finsen's method of treating lupus by means of light, has founded an institute in St. Petersburg on the lines of the one in Copenhagen. Dr. Sarapin, a Russian physician, who at the instance of the Empress, has studied the method under Professor Finsen, is placed in medical charge of the new institute, and a Danish lady has been engaged as superintendent.

Dr. Tez's typhoid extract has been tried at the University Hospital, Zürich, in 8 cases, which were chosen among the worst cases in the first or second week of the disease. After injections they rapidly improved and were free from fever within 4 days. In one other severe case which had lasted 3 weeks and in which the temperature ran up to from 103° to 105° F. continuously the injections of this serum were successful in 7 days, an ensuing relapse being also treated successfully. No deleterious effects were observed.

Tuberculin Injection for Diagnostic Purposes.—Though not an advocate of tuberculin injections for therapeutic purposes Professor Eichhorst, of Zürich, strongly recommends them to secure diagnosis in doubtful cases with pulmonary and other symptoms. The injection of one milligram of Koch's old tuberculin must be followed by a feverish reaction to secure a positive diagnosis of tuberculosis. Should no reaction follow, 3 and eventually 5 milligrams may be injected at intervals of from 2 to 3 days. A case of morbus Addisonii and a case of pseudoleukemia were thus diagnosed as based on tuberculosis.—[*Lancet*.]

Sanatorium for Tuberculous Patients.—The first annual report for 1899 of the Canton of Zürich's Sanatorium for Consumptives in Switzerland offers several points of interest. This sanatorium is situated at Wald at an altitude of 907 meters. The heliograph marked in the 4 winter months 465 hours of sunshine. There are 88 beds, of which an average of 72 were continually occupied. 319 patients were admitted and remained an average of 104 days, 36.4% belonging to the first stage (Dr. Turbin's scale), 26.3 to the second stage, and 37.3 to the third stage. Out of 76 patients in the first stage 48 were cured and 22 were eminently better. Of those in the second stage (55) none were cured and 35 were eminently better. Of those in the third stage (78) only 13 were eminently improved. These statistics go far to prove that only cases in the first and also the beginning of the second stage promise good results.—[*Lancet*.]

The First International Congress on Medical Ethics or Deontology.—In the Palace of Congresses, Paris, July 23, more than 200 medical men, coming from all parts of the world, met to inaugurate the first international congress of medical men who have gathered together solely for the purpose of discussing how to organize the profession so as to take an active part in the economic struggles of the day. Dr. Lereboullet, President of the Congress, expressed his thanks to all who in France and abroad had helped to render the Congress not only possible, but successful and representative. He pointed out that the time was propitious, for the questions at issue had now reached the domain of practical politics. He denounced quacks, the sale of secret

medicines, and unprofessional advertising, as contributing, as well as the societies that organize contract-work, to degrade the profession morally and to lower the incomes physicians might legitimately hope to earn. All these evils could only be met by the organization of strong medical unions for the purpose of defence and of educating the profession to a knowledge of its economic position. Honorary presidents were then selected from each nationality, and the general secretary, Dr. Jules Glover, gave a short account of the origin and scope of the Congress. On July 24, the first paper presented was written by Dr. Cuylitz, of Brussels, on the **Relations of medical men with benefit societies.** In Belgium there were 556 benefit societies in 1895, and in 1899 they had increased to 2,928. He estimates that out of the 6,670,000 persons that constitute the population of Belgium, 3,000,000 receive medical aid in some way or other, and do not pay the usual medical fees. He says the evil is rapidly increasing and insists that organization can only be met by counter-organization. In the afternoon, Dr. Schwalbe, of Berlin, opened the discussion on the **Conditions of practice enjoyed by medical men in other than their own country.** Some States, notably Denmark, were very hard on foreign practitioners. Great Britain was very lenient. **Hospital abuse** was the subject of a paper by Dr. Paul Thierry, of Paris. He claims that the evil—namely the use of hospitals by those who can afford to pay fees—is rapidly increasing. Physicians are frequently to blame, for they readily give letters of recommendation for treatment at a hospital to patients who should be independent. On July 25, Dr. Descourt, of Paris, read a paper on the **Illegal practice of medicine.** He considers that in Paris alone from 15,000 to 20,000 consultations are given daily by others than qualified practitioners. In regard to the **Formation of medical unions** a most encouraging report was presented by Dr. Ernest Jendrassik, of Budapest. The final paper was given by Dr. Grasset, of Montpellier University, in which he explained what is meant by the term "deontology."

The First International Congress of the Medical Press.—The inauguration ceremony of the Congress took place July 26, 1900, in the Press building at the Exposition, with M. Milleraud, the Minister of Commerce, in the chair. About 300 representatives of the medical press of the world, particularly of Europe, were present, among whom could be seen Posner, of Berlin; Ceccherelli, of Parma; La Torre, of Rome; Petersen, of St. Petersburg; Tijace, of Liege, and the editors-in-chief of the *Lancet* and of the *British Medical Journal*. At half-past two Professor Virchow, of Berlin, took his seat together with Drs. Cornil, Richet, Le Dentu, Garel, and Lucas-Championnière, and Dr. Bonnafy, Surgeon-General of the Navy. The President, Dr. Cornil, welcomed Professor Virchow and all the members and delegates of the Congress in an address in which he traced the history of the progress of medicine. The Minister of Commerce then welcomed the guests on the part of the city of Paris, and Professor Landouzy did the same for the Faculty of Medicine. Professor Virchow spoke a few words in French, in which, with a voice full of emotion, he congratulated the Association of the French Medical Press for its idea of organizing an International Congress of the Medical Press, and said that he was particularly happy about the event, because almost 60 years ago he had initiated an International Scientific Association of the same kind. Dr. Blondel reviewed the work of the Organizing Commission of the Congress, and M. Victor Mennier welcomed the members of the Congress on the part of the entire French press. The officers were then elected as follows: President, Prof. Cornil; vice-presidents, M. Bichet and M. Lucas-Championnière; secretary-general, Dr. Blondel; treasurer, Dr. Cézilly. The honorary presidents are: MM. Virchow, of Berlin; Posner, of Berlin; Fraenkel, of Vienna; Spatz, of Munich; Love, of St. Louis; Matthews, of Louisville; Vonnescio, of Bucharest; Volin, of Stockholm; Hansson, of Christiania; Valledos, of Madrid; Baccelli, of Rome; Bossi, of Gènes; Ceccherelli, of Parma; Gallet, of Brussels; Podwysowski, of Kiev; Ehlers, of Copenhagen; Tigerslid, of Stockholm; Sprigge, of London. The honorary vice-presidents are: MM. Landouzy, of Paris; Burnville, of Paris; De Muraeas, of Paris. The secretaries are: For England and the United States, MM. Smith and Fasset, of St. Louis; for Italy, MM. André Ceccherelli and Landi; for France, Drs. Romme and Regnier; for Germany, Drs. Rick

and Schober. The list of official delegates of foreign governments is: Mexico, Drs. Mentizabal, Pana, and Villareal; Norway, Dr. Rasmus Hansson; Belgium, Dr. C. van Aubel; Roumania, Dr. T. Jonnesco; Ecuador, Drs. Ricardo, Cucalon, Vivanco, Rodriguez, and Zambrant; Canada, Dr. de Martigny; United States, Dr. Alfred Osheimer. The members and delegates were then conveyed down the river to the Hotel de Ville, where they were received by the President, Vice-President, and Secretary-General of the City Council of Paris, as well as by the Prefect of Police. A luncheon was served here, and the members of the Congress were ready for the serious work to come, in the next two days.

MISCELLANY.

Plague in Turkey.—For some months past plague has been present in portions of the Turkish Empire, but has nowhere given rise to anything of the nature of a severe epidemic. In Smyrna only 17 cases have been reported in two months.

Ambulance Corps to Remain.—The Transvaal government sent an urgent appeal to the directors of the Dutch Red Cross Society to extend the stay of the ambulance corps from Holland in South Africa. The directors held a meeting and decided to maintain the ambulance service in the Transvaal until January 1, 1901.

Obituary.—MALCOLM THOMAS LYDE, at Radhanpur, Bombay Presidency, July 11.—W. LEWIS HUGHES, of Carmarthen, July 17.—ARCHIBALD H. F. CAMERON, at Chipping Camden, Gloucestershire, July 18, aged 71 years.—ALFRED SHEWEN, of Sidney, July 18, aged 57 years.—WILLIAM CHARLES STONE BENNETT, at Maidenhead, Berks, July 18, aged 43 years.—JAMES ROGERS, of Aberdeen, July 23.—DENNIS BARRY O'FLYNN, of County Cork.

Physician a Probable Victim of Massacre.—Among the medical victims of the Pekin massacre it is probable that Dr. J. J. Matignon, physician to the French Legation, must be included. He was well known for his writings on Chinese medicine and similar subjects. He was born in Eyrenesse in the Gironde in 1866, and took the degree of doctor of medicine at Bordeaux in 1892. Dr. Matignon's wide scientific knowledge and professional skill and his personal character had gained for him the esteem and confidence of the whole European colony.

The War in South Africa.—From a military point of view the progress toward a final settlement seems to be very slow. The cold weather seems to have had a beneficial influence in checking the progress of typhoid fever. The reports are much more assured in regard to it. With the limited railway transport at Lord Roberts' command, and its insufficient amount of rolling stock and worn-out locomotives, and the long distance that have to be traversed, the difficulties in supplying the army can be readily imagined. The South African Commission has begun its inquiry at Burlington Gardens, under the presidency of Lord Justice Romer.

The Medical Service in India.—To the question as to whether the services of more than one medical man had been available at most of the large famine camps, containing from 20,000 to 30,000 people, at any time during the famine or since the outbreak of cholera, Lord George Hamilton replied: "I have not received details as to the individual distribution of medical officers and medical subordinates at the different relief camps and relief houses. The famine codes contain full instructions for strengthening the medical staff in famine districts, for provision of hospital accommodation on relief works, for posting a medical officer or a subordinate qualified for independent charge to each hospital, and for the duties of such medical officers. The instructions as to engaging additional medical officers and subordinates from outside the regular service when need arises are full and clear.

Chemistry and Classicism.—To think that chemical analysis should upset our reverence for classical antiquity! Are we to be thankful because Dr. Dambergis, who presides over the science of pharmaceutical chemistry in the university at Athens, has been subjecting the waters of the springs adjacent to the temple of Esculapius at Epidaurum,

to his test tubes? The professor found that the waters contained those exact proportions of alkaline salts best suited to persons suffering from gout or rheumatism. There must have been dyspeptics in the classical age. When the votive tablets were read, it may be seen that the old Greek took the waters for the same troubles we suffer from. Of course there were cures 2,000 years ago, just as conditions are improved by a visit to Vichy or Kissingen to-day. But where does the God of Health come in? The probability is that Hippocrates knew more than he told, and was a scoffer at heart.

—[*New York Times.*]

Hints to Contributors to the Medical Press.—Professor Virchow, the editor of the *Archiv für pathologische Anatomie*, has addressed some words of counsel to the contributors to that periodical and to medical authors generally, explaining several points which it is desirable that writers for the medical press should always keep in mind. It would be difficult to find a higher authority on this subject than Professor Virchow, the patriarch of the savants and editors of Germany. His remarks are not intended for authors of books, who are at liberty to write as they like; they have been published exclusively for the benefit of contributors to medical weekly, monthly, or quarterly journals. He says that it is one of the elementary principles of journalism that the successive numbers of a journal must be issued at a certain time and in a certain size. Contributors must therefore endeavor to write concisely, taking up as little space as possible and avoiding all superfluous matter. Descriptions of cases, experiments, and necropsies when sent to editors for publications are often so voluminous that it is impossible to use them without serious inconvenience. The publications of series of cases, etc., in the form of tables is a great annoyance both for the editor, the printer, and the readers. Controversies as to priority are often offensive in style and lacking in the courtesy due to professional brethren. Finally, contributors ought to abandon the custom of quoting long passages from other authors with the object only of showing their knowledge of medical literature.—[*Lancet.*]

An Alleged Hospital Scandal.—A considerable sensation was caused not long ago by an article in the *Archiv für klinische Medizin*, wherein Dr. Strubell, an assistant in the Jena Medical Clinic, had described certain methods used by him in the treatment of a case of diabetes insipidus. Dr. Strubell endeavored to combat the disease by limiting the daily quantity of drinking-water to a very small amount, the effect being that the patient suffered very much from thirst and procured water secretly. Dr. Strubell accordingly locked the man in a room with barred windows and kept the key himself. The sufferings of the patient were described in an unfeeling manner by Dr. Strubell, who mentioned that the man was found to have drunk from a waste-pipe near the window; he was so tormented by thirst that he drank dirty water out of the washing-tub and even his own urine. Dr. Strubell's proceedings were very severely blamed, especially because the tenor of his communication might induce readers to believe that the patient was subjected to this treatment not for curative but for experimental purposes. The columns of the newspapers were filled with articles and letters on this question, and of course unqualified practitioners, homeopaths, and others joined in the general chorus of blame which was raised against the whole medical profession. Professor Stintzing, chief physician of the Jena medical clinic, said that he was responsible; that the treatment had been tried for curative purposes; that the patient had been informed of the inconveniences he might experience; that he nevertheless consented to be treated in this way; that he was at liberty to leave the hospital whenever he chose, but that he remained for two months and afterwards returned of his own accord, and up to the time of his death was always grateful to the physicians of the clinic.

Gastrointestinal Diseases of Infants.—Bergy (*University Medical Magazine*, July, 1900) voices a strong protest against the use of formaldehyd as a preservative of milk on account of the deleterious effects of the drug upon infants, which are practically starved through inability to digest milk so prepared; he also cautions against overfeeding and against the omission of antiscorbutic substances from food. [M.B.T.]

3.—Buck gives a general idea of the progress which surgery has made in the past 35 years. In his student days "laudable pus" was the delight of the surgeon, and while healing by first intention was sometimes seen, especially in wounds about the face, it was exceedingly rare. When occurring about the head or face it was attributed to abundant blood-supply. The hemostatic forceps was unknown. All ligatures were left with long ends lying without the wound. All wounds were dressed wet and covered with oiled silk. Patients, as a rule, were not bathed. The only anæsthetic used was chloroform, and no instruction was given concerning its administration. He speaks of his association with and memory of John Hilton, and his advice to students to let no opportunity to examine a rectum pass unused. The author never uses the ligature nor cautery, but rather the clamp, in operations for hemorrhoids. He does not introduce sutures in recent lacerations of the perineum, but prefers to keep the patient's legs approximated for 2 or 3 weeks, keeping the bowels loose, and irrigating the vagina daily. He feels greatly indebted to 3 men whom he never saw, Lister, Tait, and Gamgee. Lister was practically the father of aseptic and antiseptic surgery, and he was ever ready to adopt any improvement on his own methods. Tait taught us abdominal surgery, and Gamgee taught us the value of dry, absorbent dressings. The author believes in making abdominal incisions sufficiently large, and in irrigating the abdominal cavity. He speaks of the wonderful improvement often following the simple opening of the abdominal cavity of those suffering from tubercular peritonitis. He advocates intravenous injections of saline fluids, not only to combat shock, but any condition of diminished intravascular pressure. The after-treatment of abdominal operations is discussed. He prefers to give no food by the mouth for 24 hours or longer, but an enema of beef tea every 6 hours; no morphia unless absolutely necessary to relieve pain. His favorite aperient is calomel $\frac{1}{10}$ grain every quarter of an hour. [A.B.C.]

1.—Manson's second lecture on malaria and the malarial parasite deals principally with the morbid anatomy and the diagnosis of the disease. The pronounced and rapidly evolved anemia of malaria is due to the very large number of parasites found in the central circulation. The organism is not normally found, except in very small numbers, in the peripheral circulation. The periodicity of the disease may be explained, (1) by the habit of the parasite to live a more or less definite number of hours; and (2) by the diurnal rhythm in the periodicity of the physiologic processes of the human body. Pernicious attacks of malaria have been rather neglected by English writers, but are more thoroughly treated by the French. The most common type of pernicious malaria is the form known as pernicious comatose malaria, which resembles apoplexy; a second form bears a close resemblance to sunstroke, and is characterized by hyperpyrexia. Children in tropical countries frequently have epileptic seizures as the first indication of malaria. In adults, on the other hand, aphasia has been noted as a primary symptom. These attacks are due to the fact that the capillaries in the brain are crowded with malarial parasites. In some districts malaria presents the clinical picture of cholera. A practitioner in a tropical country ought always to suspect that any sudden and inexplicable attack, such as blackwater fever, may be malarial in origin. On the other hand, he should not conclude that every case of tropical disease that cannot be diagnosed positively is malarial in origin. Certain physicians in temperate climates seem to think that everyone who has passed through the Suez Canal, who has visited Rome, or who has lived in a tropical country is the subject of malarial infection. There are 3 pathognomonic tests for malaria, (1) a periodicity of 48 or 72 hours; (2) the effect of quinin properly administered, and (3) the discovery of the parasite in the blood. A periodicity of 24 hours in a syndrome cannot be depended upon in the diagnosis of malaria, since there are so many other conditions that present a quotidian periodicity. When there is an idiosyncrasy against quinin, methylene-blue may be given in doses of 3 or 5 grains 3 or 4 times a day. [J.M.S.]

2.—Chavasse presented a patient, aged 27, who had had both legs removed at the hip-joint. She had suffered from tuberculous caries of the tarsal bones of the right foot and in October, 1895, Symes' amputation at the ankle-joint was done; tuberculous osteitis occurred later at the end of the tibia, and in October, 1896, Smith's amputation was done at the knee-joint. The last stump never properly healed but became the seat of another tuberculous deposit and on May 29, 1897, Chavasse removed the femur at the hip joint; healing was extremely protracted and it was 6 months before the stump was sound. In April, 1899, she came for treatment, the left foot and ankle being very edematous and signs of fluctuation being obtained on the outer side of the ankle-joint; a large tuberculous ulcer had existed for 3 months on the lower third of the leg, the knee-joint presented the usual symptoms of tuberculous disease. The left leg was removed at the hip-joint and healing was again protracted but eventuated favorably. Chavasse has used only 2 methods of operating. In the first, anterior and posterior skin-flaps were shaped from without inward and the muscles and vessels divided high up, as close as possible to the pelvic bones, by circular incision. He considers this theoretically the best method in case of malignant neoplasm, although it undoubtedly increases somewhat the shock, while the high division of the muscles necessitates direct compression of the aorta. He has had great success whenever he has used it. The second method is known as the external racket operation, a combination of the vertical and circular incisions. This he has employed in most of his operations, varying the incisions slightly to meet the necessities of the individual case. Of the 15 operations performed on 14 patients 11 of the operations were successful and 4 patients died, a mortality of 26.6%. These cases were taken just as they occurred in practice without selection of patients. In 3 out of the 4 fatalities he thinks that deferring of the operation too long was the factor that caused the fatal issue; he quotes the figures of Estes and Wyeth with a mortality respectively of 14.2% and 12.3%, and thinks that with the improved modern technic in suitable cases there is no longer any excuse for procrastination and that surgeons are justified in urging operation when previously they merely recommended it. In early operation there is every prospect that the imme-

diate mortality will, in future, be greatly reduced even below Wyeth's figures. [M.B.T.]

3.—McWeeney reports the case of a man of 40, who complained of pain in the lower part of the chest, swelling of the neck, cyanosis, dyspnea, and collapse. The swelling of the neck was extensive, extended to the face and chest, and was due to subcutaneous emphysema. The man was of alcoholic habits and had been drunk nearly every night for 20 years. He used to vomit every morning and was much given to dry retching. On the evening before his death he had eaten tinned salmon, and the next morning had retched more than usual. He went to his customary work, but his neck became swollen, and on that account and because of the chest-pain and dyspnea he went home and to the hospital. At the necropsy a linear rupture of the esophagus nearly 1.5 cm. long was found on the anterior surface of the esophagus, just above the diaphragm. The epithelium in the neighborhood of the rupture was fairly well preserved; the subepithelial tissue was much damaged and had lost its staining power; the muscular coat was quite thick and well developed; the fibrous coat was necrotic, where it had come in contact with the extravasated fluids, and presented numerous bacterial forms. McWeeney has collected 16 other cases of rupture of the apparently healthy esophagus from the literature, which he has arranged in tabular form. He concludes that the factors causing the condition are: (1) Softening of the coats of the esophagus; and (2) sudden increase of pressure from within. The softening is partly due to intravital digestion, and partly to inflammatory infiltration. The intravital digestion may be accounted for by a circulatory disturbance, or by the retention of peptic matters in the gullet from prolonged retching. The increased pressure from within is due to the violent propulsion of the gastric contents into the lower part of the esophagus, while its upper outlet is obstructed by the contracted muscle. [J.M.S.]

4.—The authors report the case of a man of 28, a lawyer, who had been run over by a loaded wagon 7 years before. Two of the wheels passed over the thorax breaking 5 ribs and splintering a sixth; this was followed by an illness of 14 weeks' duration after which the patient began to complain of extreme weakness and anemia with periodic attacks of pain and vomiting. The attacks occurred at intervals of a week or a month and lasted from 7 to 14 days. They were accompanied by fever and sometimes by diarrhea. The blood-count showed 2,000,000 red blood-corpuscles, 54,000 leukocytes, and 30% hemoglobin. The urine examination was of negative value and a subsequent blood-count showed red corpuscles 1,000,000, 1 leukocyte to 450 reds, and 20% hemoglobin. Megalocytes and microcytes were present, but no nucleated reds were seen. An operation was decided upon for the relief of an obstructed bowel. There was a slight stricture of the small bowel just below the transverse colon with a kink in the small intestine. The patient died after the operation. At autopsy the transverse colon was found to be adherent to the small intestine and the stricture was found to be due to the contraction of an ulcer produced by the crushing of the mucous membrane where the cart wheel had pressed the intestine against the vertebrae. The serous coat of the duodenum had been crushed and healed and the upper extremity of the right kidney had been crushed and replaced by fibrous tissue. The ethmoidal air-cells were full of pus and all these factors combined to cause the pernicious anemia. There were characteristic pigment changes with large excess of iron in the liver and kidneys and intensely deep color of bile, denoting excessive hemolysis. The teeth were badly decayed and there were pus sacs at the roots of many of them. [J.M.S.]

5.—Clarke reports the case of a woman, of 22, who had had an attack of muscular rheumatism at the age of 18, followed by left-sided pleuritis with effusion. The patient complained of weakness, dyspnea, precordial pain, and edema of the ankles. During the period of treatment for these symptoms she had a sudden chill and her temperature rose to 103°. The temperature remained high for 4 days and then fell to normal, where it remained for about a week, when it again rose and prevailed over a very irregular course for 9 days. The heart presented a systolic apex murmur, a loud systolic murmur in the pulmonary area, and a faint diastolic murmur at the right base. Bacteriologic examination of blood taken from the median basilic vein gave negative results. A diagnosis of acute ulcerative endo-

carditis was made and treatment with antistreptococcic serum was instituted. Injections were given from December 31, 1899, to February 9, 1900, sometimes every day, at other times every other day, and once there was an interval of 5 days between 2 injections. The doses varied from 10 cc. to 20 cc.; usually 15 cc. was given. The patient recovered, and the cardiac examination showed the apex in the fifth interspace, in the nipple line, and a loud, blowing systolic murmur heard all over the precordium and in the back, but loudest in the aortic area. [J.M.S.]

6.—Handford speaks of the varieties in the symptoms and physical signs and varieties in causation of acute pneumonia. A puzzling symptom in lobar pneumonia that is rare is a low temperature. A case is reported in which the highest temperature recorded was 100.5°. Among the varieties in causation may be mentioned infection with the pneumococcus, *Bacillus pestis*, the typhoid bacillus, and the influenza bacillus. A series of 6 cases in one family is recorded in which the pneumonia appeared to be of the influenzal type, and to be transmitted from one to the other. [J.M.S.]

7.—Stephenson reports a case of rodent cancer of the cornea in which he operated, burning the ulcer with the galvanocautery under cocaine-anesthesia. Extreme care was used not to interfere with the clear cornea that lay in front of the pupil. Some edema and ecchymosis of the eyelids followed, as well as marked redness of the globe. Nine weeks after operation the lower half of the ulcer had cicatrized in a smooth and satisfactory way, but the remainder was roughened, uneven, and permeated by fine vessels. The operation was repeated, the galvanocautery being freely applied to the roughened portions of the cornea. The ulcer had completely healed 4½ months later, and with presbyopic correction the patient could read slowly the smallest type on Jaeger's test-card. To judge from the refraction, the operation had slightly altered the curvature of the affected cornea. [M.B.T.]

8.—Broadway reports 4 cases of puerperal eclampsia which present some points of interest. Case 1 was remarkable for the high temperature, 105.2° F., and the length of time this persisted, although there was no septic cause for it. He was called to see the patient, a strong, healthy woman of 19, the fifth day after delivery, the convulsions having begun on the third. He found her lying in a comatose condition with dilated pupils, temperature 106.2°, and pulse 140. He gave a hypodermic injection of 2 grains of pilocarpin nitrate, an enema of 1 ounce of magnesium sulfate, and 1 dram of potassium bromid, and ordered her kept on milk and soda-water, feeding her every half hour. There was no recurrence of the convulsions, though she remained unconscious several days until her temperature was reduced to 102.4°, when she became conscious and ultimately recovered. Case 3 began with convulsions the second day after delivery, but these soon yielded to a treatment similar to Case 1. In Cases 2 and 4 the convulsions accompanied or preceded delivery, and were relieved after an instrumental delivery. [W.K.]

9.—Turner reports the case of a child aged 3½ admitted for an irreducible swelling on the right side of the scrotum resembling a hernia above a hydrocele. On operation a cyst was found containing no gut and not connected with the peritoneal cavity, below it were 2 testicles. The upper one had a normal tunica-vaginalis and a distinct cord of its own and the lower and larger one was in the usual position of the testis with the sac of the tunica-vaginalis the seat of hydrocele; the left testis appeared normal. The case is of interest from the fact that the possibility of a third testis has been denied until very recently. [M.B.T.]

10.—Carter reports 4 cases of chorea, 3 of which occurred in girls, aged 13, 6, and 7 years respectively, and the fourth in a married woman, aged 25. The patients were given 15 minims of solution of arsenic three times a day until vomiting occurred, when the dose was reduced. During the administration of the drug the patients were kept in bed and on a good diet. Eighteen days was the average residence in the hospital of the 4 cases reported. [J.M.S.]

6. A Case of Enlargement of the Liver and Spleen Succeeding Chronic Catarrhal Cholangitis. STANLEY S. CORNELL.
7. Glandular Complications of Acute Follicular and Acute Suppurative Amygdalitis when Accompanied with Grip. WENDELL C. PHILLIPS.

1.—Beck says, **fracture of the metacarpal bones** is of much more frequent occurrence than was commonly supposed, now that we have the Röntgen-rays to examine them carefully. Many of the cases which were once thought to be dislocations are now shown to be fractures. In regard to treatment he says, if the immobilizing dressing is perfect, the formerly displaced fragments must be found in exact apposition, when skiagraphed through the dressing. Various experiments showed us that the metacarpal fragments are invariably held in place by elastic pressure. For this purpose two rubber drainage tubes of moderate size are chosen, which are lightly pressed into the adjoining interosseous spaces, so that they fill them up to a certain extent. They are kept *in situ* by adhesive-plaster strips. Thus the recurrence of the displacement is prohibited. The whole is surrounded then by a moss splint, a material which, after being dipped in cold water, adapts itself to the contours of the hand like a plaster-of-paris splint, over which it possesses the great advantage of being absorbent and much lighter. It frequently takes longer for these bones to unite than is commonly supposed. The dressing should never be left off until the skiagraph shows there is complete union. [A.B.C.]

2.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, No. 3, p. 104.

3.—Carstens says **appendicitis** is of more frequent occurrence than was formerly supposed. In all abdominal troubles we should look to the appendix as a possible source of trouble. Most cases of appendicitis are easily diagnosed but a few rare cases present difficulties. Beginning typhoid fever, ovarian or tubal trouble, cholera morbus, gallstones, extrauterine pregnancy, movable kidney, hysteria, etc., may all present symptoms simulating appendicitis, but ordinarily there should be no trouble in excluding any of them. The fever and pulse in appendicitis vary so much that we are often deceived in our prognosis, but the diagnosis we should certainly make. When the infection is limited to *Bacillus coli communis* the temperature is low. With mixed infection, that is, with staphylococcus, and streptococcus the fever is high and the pulse rapid. If we bear in mind that in most cases the patient first complains of pain in the region of the stomach with more or less nausea, and has a high temperature, but notice that, as often happens in such cases, the pain in the region of the stomach and the nausea subside within 24 hours, and that the only soreness complained of is in the region of the appendix (always assuming that opium has not been given), then we shall not make a mistake very often in diagnosing appendicitis. **Operate** when the diagnosis is made except (a) when the environments are bad; (b) when no experienced operator or proper facilities are at hand, and (c) in mild first attacks. [A.B.C.]

4.—In a very good paper on the **nature and etiology of hysteria**, Mix locates the seat of disturbance in the cerebral cortex. The manifestations are always functional in character and may be (1) deadening of sensory excitability of the cerebral cortex resulting in hypesthesia, anesthesia, hypalgesia, or analgesia; or a deadening of the cortical motor discharge, resulting in paresis or paralysis. (2) There may be an intensification of the perception manifested by hyperalgesia and hyperesthesia; or an intensification of the energy of the motor discharge, resulting in spasms and convulsions, often reflex in character. (3) There may be confusional interpretation of entering impulses, manifested by paresthesia; or confusion in the motor discharge, resulting in hysteria, ataxia and contractures due to imperfect distribution of motor impulses to groups of opposing muscles. The author assumes that hysteria has beneath it, as an underlying nervous defect, a perversion or confusion of the normal relationships of the neurosis. In the diagnosis of the condition it should be remembered that

every case of nervous disease should be approached with 3 ideas: that it may be functional; that it may be organic; that it may be a combination of both. One's first duty is to look for signs that cannot be functional, but that must be organic. The development of hysteria is, as a rule, gradual. The causes of the disease are predisposing and exciting. Of the predisposing causes heredity plays the most important part. Race is closely connected to heredity; the worst cases of the disease are found in the Latin races, in the Slavs, and in the Jews. Hysteria usually appears at about the age of puberty. The majority of hysterical patients are females, although the disease is common in men. Protracted and exhausting constitutional diseases predispose toward hysteria by weakening nervous control, so that a slight exciting cause may suffice for a hysterical outbreak. Diseases of the sexual organs are probably only of slight importance as exciting causes. Faulty education and home training is a last and very important predisposing cause. The exciting causes are psychical trauma, physical trauma, suggestion, and various toxemias, such as alcoholism, lead-poisoning, etc. Psychic trauma, physical trauma, and toxemias are merely special methods by which the one great exciting cause, suggestion, operates. [J.M.S.]

5.—Sheffield classifies **vulvovaginitis in children** as follows: A. Catarrhal vulvovaginitis, that may be due to (1) want of cleanliness, (2) to chemic irritation. B. Traumatic vulvovaginitis, that may be due to (1) masturbation (?), (2) mechanic injury, (3) indecent violence. C. Parasitic vulvovaginitis, that may be due to (1) oxyurides, (2) saprophytes, and (3) pathogenic microorganisms, especially the gonococcus. The author believes that it is much more probable that masturbation is a result rather than a cause of the disease, since there must be an irritated state of the erectile tissue with the inflammation of the other parts of the genitalia. In the treatment of the condition the author uses protargol solution as the safest remedy. In gonorrheal vulvovaginitis he uses a 2% solution; in other forms a 1% solution. The child is placed in the dorsal posture and the legs are spread wide apart. The exuding pus is wiped away with absorbent cotton and then a 5% solution of sodium bicarbonate is injected, $\frac{1}{2}$ ounce at a time, until the accumulated pus is removed. This is to be followed by the injection of $\frac{1}{2}$ ounce or 1 ounce of the protargol solution, which is to be retained for about 5 minutes. This process is to be repeated from 3 to 5 times in 24 hours. When the urethra is infected, the following formula is made into 12 crayons, each of which should be 2 inches long and $\frac{1}{4}$ inch in circumference: 12 grains each of protargol and iodoform, 6 drops of Peruvian balsam, 1 grain of extract of belladonna, and a sufficient quantity of cacao butter. One of these crayons may be introduced into the urethra once or twice a day. One of these crayons may be placed in the vagina at bedtime. [J.M.S.]

6.—Cornwell reports the case of a girl, aged 20 years, who had a syphilitic family history, and whose mother had died at the age of 60 years, of "jaundice." The patient complained of sudden pain in the back in June, 1899, which began in the sacrolumbar region and radiated through the abdomen toward the stomach. Since then the pain has returned at intervals of 1, 2, or 3 days. The first attack of pain was followed by jaundice, and the menstruation ceased. The attacks of pain have been accompanied by chilly feelings, followed by fever, and sometimes by sweats. The liver and the spleen were enlarged; the patient was deeply jaundiced and much wasted; she vomited solid food; she was constipated; and after alternate periods of improvement and relapse, she died. There was no autopsy. The case is diagnosed **enlargement of the liver and spleen succeeding chronic catarrhal cholangitis**. [J.M.S.]

7.—Phillips has found **simple inflammatory and suppurative involvement of the lymph-nodes very common as sequels of tonsillar affections of an influenzal character**. The author believes that absorption from the infected tonsils through the lymph-vessels was the cause of the condition. The disease has involved both the superficial and the deep cervical lymph-nodes. In one case, in which a bacteriologic examination of the pus from a suppurating lesion was made, streptococci were present. The cases on which the paper is based have seemed to be more severe than usual. [J.M.S.]

1. Cancer of the Stomach and Intestines. B. FARQUHAR CURTIS.
2. Hydrotherapy in Pneumonia. SIMON BARUCH.
3. The Use of Hypnotism in General Practice. E. H. MARTIN.
4. Some Points Bearing on the Medical Treatment of Appendicitis. CHARLES ROSEWATER.

1.—Curtis limits his paper to the consideration of **cancer of the stomach and intestines**, omitting the rectum. The mere size of the tumor in cancer of the stomach is not an indication of such extensive involvement of the glands or of such extensive adhesions as to forbid operation; tumors of the stomach may reach a large size and involve a large part of the organ without very extensive adhesions and without extensive infection of the glands. The modern technic enables removal of portions of the colon, of the liver, and even of the pancreas in these operations without serious increase of risk; some of the longest surviving cases after operation had secondary involvement of other organs. Enlarged glands may not be carcinomatous and even when the glands are infected with carcinoma a wide removal may be successful. Each case should be judged on its own merits, just as is done in cancer of the breast and other organs. The majority of the patients who died from recurrence after **pylorectomy**, not only enjoyed a period of freedom from the symptoms, but lost strength gradually, dying with less suffering than those who have not been operated upon. The chances of cure by operation depend upon early diagnosis. When a tumor is present it may be discovered accidentally before any stomach symptoms have developed, but it is often impossible to determine the real condition of affairs without opening the peritoneal cavity and examining the contents. Unfortunately a very large proportion of cases of cancer of the stomach present no palpable tumor on physical examination, at best only showing dilation of the organ and late symptoms; chemical examination of the stomach contents, although not absolutely reliable, is more valuable as a means of diagnosis. The indications for operation in cases of septic malignant disease are the presence of tumor, dilation of stomach, obstructive vomiting, marked mechanical changes in gastric contents, hematemesis, and severe gastric pain. Cancer is very often preceded by a chronic ulcer of the stomach, or develops directly upon the base of such ulcer. It is only with the development of modern methods of diagnosis and of modern surgical treatment of benign lesions of the stomach that the coexistence of a beginning carcinoma was discoverable. The clinical history in many cases will show that a grave lesion of the stomach must have preceded the cancer by years; many cases of chronic ulcer run a latent course, giving no sign until pyloric stenosis develops. Curtis cites 3 cases in his own practice in which the symptoms previous to operation proved the prior existence of ulcer. **Gastroenterostomy** will have little or no effect in relieving pain when this is the prominent symptom of the cancer for the reason that pain seldom originates in the stomach itself, but is generally due to the pressure of enlarged retroperitoneal glands on the nerves. Malignant tumors of the intestines are quite rare with the exception of those of the rectum; the sarcomas are often more frequent in the small intestines than in the large, but are so rare as to be of little surgical importance; primary carcinoma of the small intestine is also rare, the most frequent situations for these tumors being the sigmoid flexure, the splenic flexure and the ileocecal valve. Tumors of considerable size are likely to be of colloid material. The annular tumor contains a large proportion of fibrous tissue and the intestinal wall involved is contracted. The epithelial growth is very slow, the annular lesion often not extending an inch; even when symptoms of constriction have been present for a year or more the glandular involvement is equally slow. As in small tumors of the stomach the symptoms are largely, sometimes entirely, the result of mechanical obstruction, an early diagnosis of carcinoma of the intestine is seldom made and often late operations may effect a permanent cure or greatly prolong life. The mortality of **resection of the intestine** is serious but is constantly being reduced and in simple cases should not exceed that of pylorectomy. **Resection of the cecum** gives the best results. When the obstruction of the bowel is

complete, or nearly so, and the patient is in poor condition, the only proper method of treatment is to relieve the obstruction by the formation of an artificial anus, leaving the treatment of the tumor to a later period. **Intestinal anastomosis** is suitable for many cases of tumors of the intestine which can not be removed, but it should not be undertaken in the face of an acute intestinal obstruction; in the face of such obstruction the intestinal wall above is likely to be in bad condition, the point of anastomosis is likely to be near the diseased part of the bowel and in many cases it becomes involved in the disease later. [M.B.T.]

2.—Baruch considers the **indications in pneumonia** to be (1) strengthening the heart, (2) fortifying the nervous system, (3) elimination of toxins, and (4) reduction of temperature, deepening of inspiration, and the production of sleep. He uses hydrotherapy in the form of wet compresses about the chest in adults; as a full bath (at 95°–80° F.) or cold effusions (70°–60° F.) in the bronchopneumonias of children. He insists that mild cold is a stimulant, not a depressant, and produces general stimulation and especially arteriolar contraction, thus lessening the work of the heart. The compresses are made of three folds of old linen wrung out of water at 60° F. or as high as 95° F. if the fever be high and if there be much excitement. Chilling and cyanosis should always be avoided. The use of ice water internally (about 4 fluidounces at 45° F. every 2 hours) materially increases the secretion of urine. Cold is not a curative agent but fulfils the indications. [D.L.E.]

3.—Martin somewhat enthusiastically recommends **hypnotism** as being superior to drugs in a series of conditions which are exemplified by insomnia, the nausea and pressure pains of pregnancy, and "wrenched back." He also considers that it is a very helpful adjuvant to drugs and other treatment even in such grave acute diseases as pneumonia. He wisely says, however, that it should be used only when one thinks that the case demands it. [D.L.E.]

4.—Rosewater thinks that much can be done for **appendicitis without the aid of a surgeon**. The conditions in the special case must be well studied, but when the physician or patient decide against operation he recommends a calomel purge, followed by a mild saline, and a large colonic injection of salt-solution, unless there is danger of rupturing an abscess. HCl should be applied locally and opium should be avoided. The diet should be nonirritating even for months after an attack. Matting of the bowels and other organs may be to some extent avoided by the use of ammonium iodid and copious draughts of hot water. [D.L.E.]

1. The Treatment of Summer Diarrhea in Infants. CHARLES GILMORE KERLEY.
2. On Methods of Closure of Abdominal Incisions. MAURICE H. RICHARDSON.
3. The Consumptive in Los Angeles. WM. H. DUKEMAN.
4. The Evolution of the Modern Physician. WILLIAM ALFRED ELLISTON.
5. The Surgeon in the Nineteenth Century. FREDERICK TREVES.

1.—Kerley gives a brief description of the various types of **summer diarrheas**. He has found as a result of autopsies made upon 226 children dying of this condition that the lesions correspond to the duration of the illness. In the most acute toxic cases the gross alterations are slight. In the prolonged cases there is considerable ulceration. Treatment consists of elimination and diet. The former is secured by calomel in divided doses, or castor oil. In some cases the movements are infrequent, not more than 3 or 4 times per day, but are exceedingly offensive and contain large quantities of mucus. These cases require the most active purgation. The diet should be modified as soon as the symptoms appear. Milk should be stopped at once, no matter in what form it is given. If there is vomiting, the stomach should be washed and then later a little water administered. If this is not retained lavage must be employed. The foods used are barley water or flour water (two teaspoonfuls of either to a pint of water, boiled twenty minutes, and strained. At 100° F. a diastatic preparation is added). When the child recovers and milk is again given it should be modified and

not too strong. Other drugs that are useful are bismuth subnitrate and opium. The former is given in doses of 12 to 20 grains per hour. Opium is never given excepting in those cases when the movements are very frequent and when there is fever and prostration. Irrigation should be employed in cases in which the stools are infrequent and in cases where there is blood or mucus. About a pint is all that is required and to it may be added a little boracic acid or normal salt. General hygiene should be carefully observed, the clothing should be comfortable, and the child kept as cool as possible. [J.S.]

2.—Richardson, in discussing the relative advantages of layer sutures and the through-and-through sutures for closing abdominal sections, says dead spaces are unavoidable with the layer method. These dead spaces provide a place for fluids to accumulate and hence infection and hematomas are much more likely to occur. This method, however, possesses the theoretical advantage of accurately approximating the several layers of the abdominal wall. The author, however, is of opinion that the clinical facts do not prove that a firmer cicatrix is formed by this method of suturing than by the through-and-through method. He prefers a combination of the two methods. First the through-and-through sutures are passed through the abdominal wall and the edges of the wound brought near to each other, the suture ends being held by the assistant. Now as many rows of the layer sutures as desired—usually one or two—are placed, bring the wound edges together. Later the ends of the through-and-through sutures are tied. He believes this method combines all the advantages of both methods. Non-absorbable suture-material is used, silk for buried sutures and silkwormgut or silver wire for external wounds. The non-absorbable suture-material adds mechanical strength to the closed wound while the cicatricial tissue is forming and contracting. The plan of threading the suture from each end and passing the needle from within outward is preferred, because of a lessened liability to stitch-abscesses. The few cases of suppurating wounds the author has had have most all been the result of the layer-suture method necessarily employed in radical cure for inguinal hernia. Ventral hernias through cicatricial tissue are very rare, and are due more to indiscretions on the part of the patient than to any method of suturing. For three months following an abdominal incision the patient should engage in very little exercise that puts a strain on the abdominal muscles. [A.B.C.]

3.—Dukemann calls attention to the great error that many consumptives make in going to Los Angeles where they are obliged to occupy small, ill-ventilated rooms and to engage in very confining occupations in the town. He thinks their presence is a great detriment to the regular citizens. He gives some general advice, the most important of which is that all patients should live in the country, should endeavor to get well, take much exercise, and observe the ordinary precautions of those suffering from a contagious disease. He considers the serum treatment the least valuable of all the therapeutic measures suggested for consumption. [J.S.]

4.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 226.

5.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 183.

Boston Medical and Surgical Journal.

August 2, 1900. [Vol. cxliii, No. 5]

1. Asphalt Pavements; Their Nature and Desirability. CLIFFORD RICHARDSON.
2. The Transportation of Disease by Dust. HAROLD C. ERNST.
3. Effects of Dust Upon the Lungs. VINCENT Y. BOWDITCH.
4. The Effects of Dust on the Upper Respiratory Tract. SAMUEL W. LANGMAID.
5. Recurrent Luxation of the Ulnar Nerve. F. J. COTTON.

1.—Richardson, in an article read before the Boston Society for Medical Improvement, gives a concise and clear history of the employment of asphalt for paving, together with a description of the sources of supply and the nature of the substance itself. He believes that the ordinary lake asphalt, such as that found in the island of Trinidad, unquestionably the best for paving purposes, and that the mixture of sand renders it equally satisfactory for a foothold for horses as any other form of pavement. He describes the

method of laying the pavement in 3 parts, the base, the binder, and the asphalt surface, the second being designed to prevent the latter from sliding. It has the following advantages over other pavements: Its surface offers the least resistance to traction consistent with a good foothold for horses; it is impervious to moisture; it offers no irregularities for retaining dust; produces practically no detritus itself; it is easily cleaned and is as noiseless as possible. The first cost is considerable, but as it is usually guaranteed for five years, it in the end is probably the cheapest form of pavement. Another marked advantage is the readiness with which it may be repaired. It sustains the heaviest traffic, increases the value of property, and in comparative studies has shown that less dust can be collected from asphalt surfaces than from any other. It diminishes the number of repairs required by vehicles. The amount of saving in this respect for the City of Philadelphia is \$100,000,000 per annum (?). It apparently reduces the death-rate very considerably, does not prevent the escape of illuminating gas from leaking drains, and in all respects is at present the most desirable form of paving. [J.S.]

2.—Ernst has studied dust. He quotes the work of Germano, who studied in relation to it the typhoid and diphtheria bacilli and the streptococcus and pneumococcus, besides a number of others. All of these showed that most of the bacteria could not resist prolonged drying, and Coolidge therefore concludes that it is the irritant particles in the air that are most dangerous. [J.S.]

3.—Bowditch calls attention to the extremely dirty condition of Boston due to the filthiness of its streets. He has collected a twenty-pound butter firkin full of various kinds of filth from his own doorstep in the course of 4 hours. [J.S.]

4.—Langmaid calls attention to the fact that after a high windstorm which creates a dusty atmosphere, an epidemic of sore-throat is very common. He believes that the quantity of dust depends largely upon the nature of the pavement. Other mucous membranes are also likely to be irritated. [J.S.]

5.—Cotton details 3 cases of recurrent luxation of the ulnar nerve, saying that this condition, although it has been definitely described, is not often mentioned, perhaps not always recognized. The first was in a woman of 25, who fell, striking her elbow; she had much pain on the inner side of the elbow on motion and a thick cord was felt lying in front of the internal condyle; on extension this cord slipped back upon the epitrochlea to the normal position of the ulnar nerve, and the nerve in luxation came forward well in front of the epicondyle. The arm was put in a splint at an obtuse angle and a pad placed over the internal condyle to guard against luxation of the nerve. Four months later she could use the arm nearly as well as ever and complained only of occasional pains in the hand. The nerve still slips out of its normal place when the elbow is flexed, but slips only inward to the tip of the epicondyle, not in front of it. The second case was in a girl of 11, following a fall upon the elbow; the ulnar nerve slipped out of place, with flexion of the elbow when an angle of 60° of upper arm and forearm was reached, moving inward and forward a little anterior to the internal epicondyle; the nerve-trunk was not obviously thickened. The arm was put up in an internal angular splint at a right angle. There was gradual improvement until an approximately normal condition was reached, except that the subluxation still occurred in flexion. The third case, also the result of a fall, occurred in a boy of 10, and was really only a subluxation. The patient did not return after the first examination. Cotton is of the opinion that the nerve-symptoms, not the lesion in itself, should first be considered in deciding between conservative and operative treatment aimed at the reformation of the groove to contain the nerve. [M.B.T.]

4. Myofibroma Uteri. HERMANN J. BOLDT.

the temporal and auditory region. The upper lid was much swollen and edematous, and there was chemosis of the ocular conjunctiva. Ophthalmoscopic examination showed the retinal veins to be enlarged and tortuous. There was a marked bruit in the temporal region. When the left common carotid artery was forcibly compressed for a short time, the affected eye slowly sank into place. Digital and mechanical compression upon this artery was tried for 11 days, but the condition became worse and the bruit so intense as to be almost unbearable to the patient. The left common carotid was ligated, the eye resumed its normal position, and gradually the swelling of the lids subsided. The eye became totally blind, there being present a condition of absolute secondary glaucoma. Oliver is of opinion that a head-crush, which was received when the patient was 4 years of age, most probably caused either an **aneurysmal varix**, situated between the petrous and the cavernous portions of the internal carotid and the corresponding cavernous sinus, or a **varicose aneurysm**, in which there was an intervening sac between the two vascular channels. The recent blow upon the diseased region, in a debilitated subject, increased the opening into the venous structure, so as to give as its most prominent ophthalmic sign an orbital varix. [C.A.O.]

5.—Arneill, after experimenting with Ehrlich's diazo reaction, says the results of his observations have been to confirm in most particulars the statements of Ehrlich. They also agree with the results published in 1893 by Warthin. The fact that during the past 8 years the test has been made in the same way in his clinical laboratory makes the author's results trustworthy. He says, in deciding upon the clinical value of the Ehrlich diazo reaction, we can fairly discard the work of all investigators who have not performed the test in accordance with the directions laid down by Ehrlich, or who have not considered the **pink foam** as the important factor in the test. In this list are included the names of Petzoldt, Petri, von Jaksch, Munson and Oertel, and Edwards. These statistics, presented by numerous investigators who have performed the test correctly, are overwhelmingly convincing as to the value of this reaction in the diagnosis and prognosis of typhoid fever, and the prognosis of disease such as pneumonia, diphtheria, septicemia, and especially tuberculosis. The author states that all cases of tuberculosis giving the diazo reaction continuously for several days may be considered in the third stage of the disease. In such cases the prognosis is grave and the patients will not be benefited by a change of climate. Out of 22 cases of typhoid fever, 19 gave the diazo reaction; 3 which failed to give the reaction were very mild. [C.A.O.]

6.—Chadbourne describes the case of a woman of 36 who had had typhoid fever and inflammatory rheumatism of the lower extremities, and who at the age of 31 began to have epileptic seizures which appeared to be of the type of idiopathic grand mal. She complained of dyspnea, became cyanotic, had to be propped up in bed, and had marked edema of the feet and puffiness of the face. The heart-dulness was enlarged to the left, with a blowing murmur at the apex. The woman suddenly died and necropsy showed a complete obliterating chronic pericarditis. The heart was extremely flabby and there were minute atheromatous spots in the aorta and coronary arteries. In the examination of the whole fresh organ it was discovered that both the **mitral and tricuspid orifices were so narrow** as to admit only the tip of the index finger, the edges being thick, rigid, and almost cartilaginous in consistency. All the chambers were much distended without much hypertrophy of the ventricular walls. In view of the postmortem findings the author is inclined to view the epileptic attacks as belonging to a type of convulsions known as "cardiac epilepsy." [C.A.O.]

7.—Steele, after an exhaustive review of the literature on the subject, finds 61 cases of **retroperitoneal sarcomas**. After making a study of these cases he comes to the following conclusions: 1. Retroperitoneal sarcomata, while rare, occur with sufficient frequency to warrant more attention from the standpoint of diagnosis than they have heretofore received. 2. Males appear to be somewhat more predisposed than females (60 to 40%). The condition is more common in the first, fourth, fifth, and sixth decades of life. Traumatism does not seem to play much of a part in their causation. 3. It is a quickly-growing tumor, the average duration in 30 cases being 87 months. 4. The tumor gener-

ally originates in the lumbar region (57%). The next most frequent seat is the central portion of the posterior wall of the abdomen, about the attachment of the mesentery (41%); 2% grow from the pelvis. Lateral tumors are more frequently on the right than the left side. The tumor is prone to degeneration, and such degeneration is oftenest hemorrhagic in character, but may be puriform or myxomatous. Metastasis is not common, but when it occurs, the liver and lungs are oftenest affected. In the majority of cases the growth involved the intestine and the softened central area tended to rupture into the gastrointestinal tract or the peritoneal cavity. 5. The onset is insidious. The earliest manifestations are functional disturbances of the digestive tract. The first symptoms that are characteristic are those of pressure upon the lumbosacral nerves and upon the venous supply of the lower extremities, manifested by neuralgic pains or edema of the feet and legs. 6. In the earlier stages the physical examination is difficult; in the middle stages the colon is pushed up and lies upon the anterior surface of the tumor. In the lateral growths the small intestine is pushed to the opposite side of the abdomen, and lies in an irregular circle around those occupying the median position. This arrangement of the bowel is very characteristic of all retroperitoneal growths. The tumor may fluctuate and may move with respiration, or be movable by palpation. 7. The pressure symptoms and evidences of intestinal obstruction are the most valuable points in differential diagnosis. It is often impossible to distinguish the growths of the retroperitoneal space from those of the kidney and suprarenal capsules by physical examination alone. The difficulty of diagnosis is increased when the growth fills the abdominal cavity. An exploratory incision is the only sure method. Surgical interference offers the only opportunity for prolonging the patient's life. [C.A.O.]

Berliner klinische Wochenschrift.

1. The Nourishment of Infants and Infants Diseases. ADOLF BAGINSKY.
2. What Are Our Opinions with Regard to Getting Rid of Infectious Diseases, Particularly Tuberculosis. W. DÖNITZ.
3. The Treatment of Nevus and Similar Congenital Conditions. E. HOLLANDER.
4. The Pest in the Light of Later Investigations. P. FROSCH.

1.—An interesting review of the history of the development of **infant feeding**. [D.R.]

3.—Hollander finds, as the result of considerable experience in the treatment of birthmarks, that cauterization with **superheated air** is the best method of treating growths which it is impossible to extirpate. This method is much preferable to the painful, repeated puncture with the thermocautery, which has been recommended by some surgeons. There is no loss of blood, the scar is hardly noticeable, unless the **nevus** is extensive, and the method is applicable to all parts of the body and on the mucous membranes. When the air-stream strikes the parts they first become pale, they then shrink and dry to a leathery consistency and appearance. The after-treatment is that usual for any granulating wound. No very definite directions as to the use of the method are given. [M.B.T.]

4.—There are **three forms of plague: bubonic, pulmonic, and dermal**; the pulmonic form is prognostically the most unfavorable. Its diagnosis is often very difficult; the great gravity of the disease, the profound prostration of the patient, and the rapid death (in from two to three days), should arouse suspicion. The poison in the bubonic form usually enters through small lesions of the skin, although there are some who hold that infection may occur through the unbroken epiderm. Plague septicemia and plague pyemia are not independent forms, but are due to the entrance locally of the bacilli; in the pyemic form metastatic deposits of bacilli are found in various internal organs; lung, liver, spleen, brain, etc. The lesions are the size of a hazelnut, yellowish-white or grayish, are surrounded by an inflammatory zone, and harbor innumerable bacilli. There is every reason to believe that there is a toxin produced in plague; the marked nervous symptoms and the occurrence of hemorrhage into the tissues constitute strong

evidence. It is also proved by the findings in the fetuses of plague-infected mothers. Although bacterially sterile, these have shown the characteristic visceral lesions of plague, viz: the hemorrhages into the organs. There is no special *facies pestica*. The disease as a rule sets in acutely after a period of incubation averaging five days. The most dangerous form of plague, so far as the hygienic combat against the disease is concerned, is the pulmonic form, on account of the fact that innumerable bacilli are contained in the secretion of the lungs. Many of the lower animals are susceptible, only the birds having so far shown themselves refractory. Rats and guineapigs are so sensitive that the mere application of the smallest quantity of culture to the intact skin invariably causes their death from plague. As rats and other rodents are probably spontaneously susceptible, they constitute one of the chief dangers of the spread of the plague. It may be that the disease is maintained endemically in certain localities through the medium of rodents. In an endemic plague-focus in the Himalayas there exists a species of *Arctomys* that is subject to an epidemic disease closely resembling the plague in man. Epidemics usually begin in an insidious manner with a few scattered cases, and gradually increase in intensity. They subside in the same way. A relation between the disease and the soil, climate, altitude, temperature, and season cannot be discovered; nor does age, sex, race, or occupation have any influence upon the mortality. The hygienic conditions, however, are of great importance. The dissemination of the bacilli through insects is possible, but probably does not play an important role. Different states have taken active measures to combat the disease, and a congress was held in Venice to settle upon questions of quarantine. Frosch is a believer in prophylactic vaccination against the disease. [D.R.]

1. The Demonstration of Bone Structure by Röntgen-Ray Pictures. JULIUS WOLFF.
2. Combating Tuberculosis as a General Disease. WILHELM WINTERNITZ.
3. The Occurrence of Peculiar Crystals in the Bones of Rachitic Children which were Treated with Suprarenal Substance. STOELTZNER and SALGE.
4. What Are Our Opinions as Regards Getting Rid of Infectious Diseases, Particularly Tuberculosis. W. DÖNITZ.

2.—Winternitz believes that **hydrotherapy** is of great value in the prophylaxis and treatment of tuberculosis, and sums up his conclusions as follows: 1. Prophylaxis: The increase of the resistance of all those threatened with tuberculosis by cold baths, effusions, or douches. 2. In the sanatoriums and people's baths provision for hot, warm, and cold, automatically-regulated shower-baths, steam baths, etc. 3. Sanatoriums in all hospitals, with provision for cold and carbon dioxid douches. A trained staff to give cold rubbings and apply chest compresses. 4. The providing of all phthisis sanatoriums with simple devices in the sleeping-rooms for giving cold or carbon dioxid douches. By the hydrotherapeutic method he claims to have achieved arrest or relative cure in 80% of the cases of chronic *afebrile phthisis*; in *phthisis florida*, in 32% more or less prolonged arrest and relative cure. In the incurable cases the method produces comfort and awakens hope of cure. [D.R.]

3.—The authors describe the occurrence of **crystals** in the bones of 3 cases of *ricketts* that had been treated with suprarenal extract. The crystals are soluble with difficulty in alcohol, readily soluble in water, and have a remarkable affinity for silver salts. [D.R.]

1. Condition of the Urine after Palpation of the Kidney. C. MENGE.
2. A Special Form of Chronic Icterus. BETTMANN.
3. The Treatment of Joint Effusions by Hot Air. RUDOLPH KLAPP.
4. A Case of Idiopathic Distention of the Esophagus. GUTTENTAG.
5. A Case of Tuberculous Cerebrospinal Meningitis Cured. M. HENKEL.

6. Koplik's Spots by Measles. KARL MANASSE.
7. Agglutination of Intestinal Bacteria by the Blood-serum in Typhoid Fever. F. KÖHLER and W. SCHEFFLER.

1.—The author found **albumin and blood in the urine** in small quantities **after palpation of movable kidneys**. The appearance of the abnormal constituents depends (1) on the forcibleness and the duration of the palpatory pressure; (2) on the general nutrition of the patient; (3) on the tension of the abdominal walls; (4) on the degree of nephroptosis; (5) on the sensitiveness of the palpated organ. The author seems to be of opinion that many cases of cyclic or periodic albuminuria are connected with pressure upon the kidneys. These intermittent forms of albuminuria are most frequent in childhood and at puberty, especially in lean individuals. The albumin is usually present only in the daytime after the patients have left the bed and assumed an upright position; in other words, at a time when the kidneys descend lowest and are subject to the pressure of the clothing. [D.R.]

2.—Bettmann's case tallies with those described by Hayem, under the term "*ictère chronique infectieux splénomégalique*." The patient was a merchant of 29, who had had jaundice for a number of years. The bowels were never clay-colored. There was no bile in the urine. The liver was not enlarged, but there was an enormous **splenic tumor**. No definite cause could be found for the condition. An interesting point was that the patient seemed to be subject to **paroxysmal hemoglobinuria**, and the author suggests that this may have played a part in the production of the splenic tumor. Regarding treatment, tonics seemed to be indicated; potassium iodid and arsenic were of no value. The question of splenectomy was negated on account of the fact that the splenic tumor was probably merely the result of the effort of the spleen to store and elaborate the hemoglobin set free in the serum. It was, in other words, a so-called *spodogenic splenic tumor*. [D.R.]

3.—A report of a number of cases of **joint effusion** benefited by the **hot-air treatment**. Experiments on animals are reported in which it is shown that when saline solution is injected into the peritoneal cavity, and the animal subjected to heating, the solution is much more rapidly absorbed than under ordinary conditions. [D.R.]

4.—Guttentag reports an interesting case of **idiopathic dilation of the lower end of the esophagus**. The patient was 17 years old, and first noticed the beginning of his ill health 5 years before. It began with difficulty in swallowing, and recently there developed vomiting of uncurdled milk which he had drank many hours before. A soft stomach-tube was easily passed for 40 centimeters, when it seemed to enter a dilated portion of the esophagus, from which could be emptied some 50 cubic centimeters of liquid contents which did not contain free hydrochloric acid. With a little difficulty the tube could be passed 8 centimeters further, when it was found to enter the stomach, as shown by the contents containing free hydrochloric acid. Inflation of the stomach with carbon-dioxid showed that this organ occupied its normal position, the greater curvature reaching to within 2 finger-breadths above the umbilicus. The patient could empty the esophageal reservoir by pressing firmly over the sac. [G.B.W.]

5.—The author reports the **recovery** of a case of undoubted **tuberculous cerebrospinal meningitis**, tubercle-bacilli having been found in the fluid obtained by lumbar puncture. [D.R.]

6.—**Koplik's spots** are often valuable as an early symptom of measles, but they may be present without measles following or they may be absent when measles exist. [D.R.]

7.—The author's conclusions are as follows: Colon-bacilli are often agglutinated by the serum of normal individuals. Frequently the serum of typhoid fever patients which **agglutinates typhoid bacilli** does not agglutinate the colon-bacilli cultivated from the stools of the same patient; at times it does agglutinate them. The serum of typhoid fever patients may not agglutinate the colon-bacillus, while the serum of a healthy individual may do so. The conditions under which the serum of typhoid patients agglutinates those colon-bacilli isolated from their stools, and those under which the serum of healthy persons agglutinates colon-cultures are entirely unknown. The view of Pfandler that the

serum of human beings during the course of life acquires the power to agglutinate intestinal colon-bacilli has not been proved. A differentiation between the typhoid bacilli and the colon-bacilli through the serum-reaction is not possible. [D.R.]

Deutsche medicinische Wochenschrift.

June 23, 1900. [26. Jahrg., No. 25.]

1. Examination of the Behavior of the Milk Bacteria in the Milk Thermophore. DUNBAR and W. DREYER.
2. Danger of Conveying Tuberculosis Through Milk and Milk Products. LYDIA RABINOWITSCH.
3. Fat Emboli. HUGO RIBBERT.
4. Concerning Iodipin. VICTOR KLINGSMÜLLER.
5. A New Pathologic Club-shaped Bacterium of the Lymph. E. LEVY and H. FICKLER.
6. The Significance of the Oliver-Cardarelli Sign. SIGMUND v. RITOOK.
7. Rare Complication in Tracheotomy. E. THOMAS.

1.—The authors investigated the value of the **milk thermophore** in the limitation of the growth of bacteria in milk. They decided that after allowing the milk to stand 10 hours in the thermophore no growth of bacteria is seen in the milk. On the contrary, in pasteurized milk, or raw milk, the bacteria decreased decidedly in number, and often no cultures of living bacteria were obtained. Therefore, there is no danger of any change in the milk when it is kept in the thermophore. They consider this instrument a valuable one for preserving milk temporarily for the use of children. It is one that may be readily used by nurses, etc. [D.L.E.]

2.—Rabinowitsch investigated 8 samples of milk specially prepared for children. They were not sterilized. In 3 instances the milk came from herds in which the **tuberculin-test** is regularly used and affected animals are excluded from the herd, while in 5 other cases the tuberculin-test was not regularly carried out. In 3 of the former the bacilli were regularly absent, and in 3 of the 5 herds of the latter class virulent tubercle-bacilli were repeatedly found. Rabinowitsch also found streptococci in considerable number repeatedly in special milk for children. She has several times found tubercle-bacilli in kefir, and thinks that this preparation should be made only from pasteurized milk or from milk from cattle that have been tested with tuberculin. Bacilli were absent from 2 specimens of plasmon examined, but they were found in both the specimens of sana (an artificial preparation of cow's fat). Rabinowitsch therefore decides that these investigations show even more forcibly than before the necessity for the use of tuberculin-tests in cattle which supply milk. [D.L.E.]

3.—Ribbert believes that **fat emboli** are the result of shocks and blows against the bones and not of direct injuries of the veins following upon fractures. The fracture itself, he believes, has very little to do with the occurrence of fat emboli the blow being the actual cause through the violent disturbance of the bone-marrow which sets free fat emboli and results in their lodgment in the veins and subsequently in the small arterioles or capillaries. He has regularly found emboli in every case of trauma that was associated with severe contusion of the bones, and he found that dropping rabbits from a moderate height upon the floor, while associated with no fracture, was practically always associated with fat emboli. He thinks that fat emboli frequently result in human beings even after jumping from a moderate height, though they are of no clinical consequence as a rule under these circumstances. [D.L.E.]

4.—The author has in all used subcutaneous injections of **iodipin** in about 100 cases. The results were extremely successful, and the conclusion that he reaches is that the subcutaneous use of iodipin is an extremely valuable one. It is an easy method and the effect is certain, energetic, and protracted. [D.L.E.]

5.—The bacterium described is believed to belong to the diphtheria group, and to be one of the class commonly called **pseudo-diphtheria bacilli**. The authors place it in the group of the actinomycetes. They have no definite statements to make as to its relation to vaccinia. The cultural and morphologic characteristics are described at length. [D.L.E.]

6.—Ritook reports a case of aneurysm of the innominate artery in which there was marked pulsation of the larynx both laterally and vertically which could be both seen and felt. Pulsation, however, was from beneath upward, and not from above below. In another case he found the tracheal tug and the **Cardarelli symptom** with no other associated symptoms of consequence excepting stenotic breathing. The postmortem showed primary tuberculosis of the bronchial glands. It is intimated that these glands were adherent on one side of the aorta and on the other side to the left bronchus. This, however, is not definitely stated. Another case, which is of much interest, proved to be a left-sided circumscribed pleural effusion, which disappeared almost entirely after aspiration and the subsequent use of salicylates. This effusion had caused a decided tracheal tug. The explanation of this was that the fluid collected in the circumscribed area, and the costomediastinal space had crushed the aorta down upon the left bronchus, and had thus given rise to the tug. The author insists, however, that these cases do not show that the symptom lacks value. Such opportunities for error are extremely rare. [D.L.E.]

7.—The complication of tracheotomy reported by Thomas consisted in a form of cicatricial contraction of the sternohyoid muscles which pulled the larynx so far downward that it was surgically impossible to approach the trachea. At the operation, which was being performed for diphtheric stenosis, the larynx was the only available portion of the respiratory tract, and this was consequently opened, but the opening so high up failed to give sufficient relief, so that the patient died in a very few minutes. The postmortem showed the true state of affairs. [G.B.W.]

Sundry French Journals.

1. Endotheliomas of the Bone. L. THEVENOT. (*Revue de Chirurgie*, May 10, 1900. 20me Année, No. 5.)
2. Splenomegalic Biliary Cirrhosis. CHAUFFARD. (*Sem. Méd.*, May 23, 1900. 20me Année, No. 22.)
3. The Identity of the *Bacillus Lactis Aerogenes* and the *Pneumobacillus* of Friedländer. GRIMBERT and LEGROS. (*Sem. Méd.*, May 23, 1900. 20me Année, No. 22.)

1.—In concluding his paper on **endothelioma of the bone**, Thevenot states his belief that with his case only about 14 cases have been seen thus far reported which deserve to be so classified, and in which thorough histologic examination was made. Probably many earlier observations of aneurysms of the bone deserve this name, but histologic examination was lacking. The permanent results are seldom reported, and it is impossible to give any definite statements with regard to prognosis. The patients usually die of general extension of the disease. In case of doubt an early conservative operation is recommended. [M.B.T.]

2.—Chauffard divides the cases of **hypertrophic biliary cirrhosis with splenic involvement** into 3 classes. 1. Those in which the spleen and the liver seem to be attacked simultaneously and to an equal degree, which may be termed splenomegalic hypertrophic biliary cirrhoses. 2. Those in which the spleen is undoubtedly diseased before the liver and to a greater degree; they are thought to be instances of hepatitis of splenic origin and may be known as metasplenomegalic hypertrophic biliary cirrhosis. 3. Those in which the hepatic lesion precedes and appears to be the cause of the change in the spleen; these may be known as presplenomegalic hypertrophic biliary cirrhosis. [J.M.S.]

3.—The study of the morphologic and biochemic characters of four typical specimens of the **Bacillus lactis aerogenes** has led the authors to admit the complete identity of that organism with the **pneumobacillus** of Friedländer. The bacilli that have been studied are immobile; they do not stain by Gram's method; they do not produce spores; they become encapsulated in pus, in the blood, and in the serous exudates of inoculated animals; they are facultative anaerobic organisms; and their cultures in 3% peptonized water never produce indol. Baked albumin is not modified by them and milk is rapidly coagulated by acidification, without alteration of the casein. The bacilli in question ferment glucose, lactose, saccharose, and dextrin with the production of ethyl alcohol, acetic acid, lactic acid and succinic acid. [J.M.S.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Cannabis Indica.—Lewis (*Merck's Archives*, July 1900) states that he has found cannabis indica most efficient in relieving the various neuroses accompanying pregnancy and the climacteric, and believes that for allaying the violent nerve-storms of the artificial menopause it is without an equal. In dysmenorrhea, not due to anatomical or inflammatory causes, no drug acts so promptly and with fewer after-effects. The drug is very useful in profuse menstruation, decreasing the flow without completely arresting it, as ergot frequently does.

Lithemia.—Bruce (*Treatment in Practical Medicine*) recommends the following antacid and stomachic mixture:

R.—Bicarbonate of sodium 15 grains.
Aromatic spirits of ammonia 10 minims.
Compound infusion of gentian to make 1 ounce.

Three times a day, 5 minutes before meals.

Alternative and tonic mixtures like the following are sometimes serviceable:

R.—Fowler's solution 3 minims.
Tincture of nux vomica 5 "
Ammonium carbonate 4 grains.
Spirit of chloroform 8 minims.
Infusion of quassia to make 1 ounce.

Three times a day immediately after meals.

The Treatment of Appendicitis.—Gaub (*Pennsylvania Medical Journal*, July, 1900) reports 124 cases of appendicitis, with 15 deaths, a mortality of 12.1%. Two patients were in extremis on admission. Thirteen patients were not operated on for various reasons. Of 109 cases in which there was an operation, there were 12 deaths, a mortality of 11%. From the study of the cases presented, the writer concludes:

1. A typical cure by nature is the exception.
2. Nature may adapt herself to the pathologic conditions present, to the patient's comfort and longevity.
3. The first attack of appendicitis usually determines the outcome with regard to fatality.
4. Any type of appendicitis may lead to a fatal issue.
5. In 50% of the cases the process proceeds to abscess formation.
6. We may expect a mortality of 10% in abscess cases operated late in the disease.
7. Cases of acute septic peritonitis, complicating gangrenous appendicitis, have always been fatal.
8. In abscess cases death is due to rupture, metastatic abscesses or toxemia.
9. At the present time we are unable to map out the clinical course of the disease from the symptoms, etc., at its onset.
10. Early operation offers the best results in appendicitis.
11. Progress in appendicitis must aim at the early recognition of the intensity of the infection, as typified in a gangrenous appendicitis.

Pulmonary Tuberculosis.—Foxwell (*Essays in Heart and Lung Diseases*) states that when there is great exhaustion and the sputum clings about the throat and trachea, so that the patient experiences an agonizing dread of being choked, the application of lemon and glycerin to the fauces is useful, and that the following mixture does more than any medicine of which he knows towards maintaining life and producing euthanasia:

R.—Spirits of ether }
Aromatic spirits of ammonia } of each.... 30 minims.
Tincture of orange 10 minims.
Camphor-water to make 1 ounce.

To be taken every 6, 4, or 2 hours.

Cacodylic Acid.—Frassi (*Gazz. degli osped.*, March 18, 1900) has studied the action of cacodylic acid in chlorosis and tuberculous affections. The treatment was carried out for a long period. The drug was given hypodermically, the strength of the solution being gradually increased. At first the injections were given every other day, but later, daily. The injections did not excite pain, and were never followed by symptoms of intoxication. In chlorosis the treatment

was always followed by a gain in weight, and a marked increase in the elimination of urea, while at the same time the quantity of urine was diminished. As in the case with arsenic, cacodylic acid diminishes the oxidation of the hydrocarbons, and increases the decomposition of the proteids. In tuberculosis the general effect of the drug was more noticeable than the local action. As regards the action of the drug on the blood the author finds that while the hemoglobin is constantly increased, the influence on the number of cells is much more marked. Iron, on the other hand, affects the hemoglobin more than the number of cells. Arsenic is, therefore, more cytoplasmic in its action than hemoglobinoplastic. When administered hypodermically, cacodylic acid is eliminated in the urine, from which it is recovered unchanged.

The Bath-Treatment of Typhoid Fever.—Bäumler (*Sonderabdr. aus Deutsch. Archiv f. klin. Med. and British Medical Journal*, June 14, 1900) gives the results obtained in 1,019 cases of typhoid fever by the cold-bath treatment in the medical clinic of Freiburg-in-Breslau. The mortality, which was 9.32%, or, excluding cases which were moribund on admission, 7.9%, contrasts favorably with Sydney Philip's estimate, made in 1898, that the average death-rate from typhoid fever was still 18%. Baths act not so much by lowering the temperature as by improving general nutrition through the circulation and nervous system. Several factors influence the circulation; the peripheral vessels contract, the difference between the arterial and venous blood pressure, on which depends the rate of flow in the vessels, is accentuated, and the heart is stimulated mechanically; at the same time the respirations become deeper. For any permanent benefit to be obtained it is essential that the baths should be repeated frequently, so that the flow of blood from the peripheral to the central parts and from the central to the peripheral continues uninterruptedly. It is an open question whether the bath-treatment has any influence on the mortality from intestinal perforation, and on the mortality from hemorrhage it has almost certainly none. Apart from intestinal lesions the greater number of deaths (27.3%) were due to pulmonary complications, though bronchial catarrh was certainly less common than in cases treated without baths. The reason for this is that, owing to the comparatively good general condition of the patient, descending tracheobronchitis from the inhalation of infected material from the upper air-passages—and this is the commonest cause of bronchial catarrh in typhoid fever—is avoided. It is most important to give the patient a drink of water after every feed in order to remove any remnants of milk or other decomposable material. As a rule the heart stands repeated baths excellently, and they are not generally contraindicated in cases complicated by nervous tachycardia, or by a rapid pulse due to pulmonary changes (emphysema, fibrosis, or chronic bronchitis) even when accompanied by great cyanosis. The same is true of cases complicated by anemia and fatty degeneration of the heart, though naturally caution is necessary. Practically, then, the only contraindications are abdominal pain and collapse, and when peritonitis, perforation, or hemorrhage are suspected. The actual technic used at Freiburg is as follows: Whenever the temperature in the axilla reaches 103° F., a bath at from 82.4° to 75.2° is given. The patient remains in it with his head resting on an air cushion until he begins to feel cold, generally from 8 to 10 minutes, the skin, especially over the extremities, being rubbed constantly. After the bath he is wrapped in a dry sheet and covered with blankets; a hot-water bottle is placed at the feet. Some wine is given before the bath, and immediately after it more wine and hot soup. If there is great mental dulness, delirium, or pulmonary catarrh with atelectasis, or bronchopneumonia, cold water at 50° F. to 59° F. is poured over the patient for a short time at the end of each bath. Whenever possible, one bath should be given during the night. If the first bath is well borne, and the patient's strength is maintained, the temperature of the baths is soon reduced to 68° F. The diet should be liquid, and not too much alcohol should be given; large quantities relax the arteries and have the same action as the typhoid toxins. When there is great cardiac weakness, camphor is very useful and ammonia may be tried. Antipyretic drugs are only harmful. The patient should be made to drink large quantities of fresh cold water all through the illness.

Original Articles.

MILITARY SURGERY.

By W. C. BORDEN ("EDRO"), M.D.*

Captain Medical Department U. S. Army; Professor of Surgical Pathology and Military Surgery, Georgetown University, Washington, D. C.

MILITARY surgery may be defined as the application of surgical methods, under the conditions which obtain in war, to the treatment of traumatisms made by military weapons.

In military surgery three main factors present themselves for consideration: First, the character of the traumatisms inflicted in war; second, the treatment to be adopted; third, the conditions under which the patient is placed during treatment. The practice of military surgery therefore demands of the military surgeon a knowledge of these factors and of their relation to each other.

It may at once be stated that of these factors two are of preeminent importance in modern military surgery. These are the character of the wounds inflicted by the small-caliber compound bullet now so largely used, and the effect of the application of the principles of aseptic and antiseptic surgery to the surgery of war. The first derives its importance from the fact that the great majority of wounds in war are due to rifle fire; the second, to the fact that aseptic and antiseptic methods are applicable to all wounds however inflicted, and that the application of these methods has as greatly affected the treatment, progress, and prognosis of the traumatisms of war as they have surgery in general.

It is necessary, therefore, to consider the character of wounds received in war, both in their immediate and remote effect, their course and treatment, and the conditions under which the patient is likely to be placed, during the time of treatment. Traumatisms which might be treated conservatively in civil practice, often require radical operations under the environment and conditions incident to military surgery; and, on the other hand, injuries which, in civil practice, would require immediate surgical intervention, are frequently best treated expectantly, under the conditions which obtain in the field. The latter is well illustrated in the difference which obtains in civil and military surgical treatment of gunshot wounds of the abdomen. With the resources of the civil hospital and surrounded by aseptic safeguards, the civil surgeon uniformly opens the abdominal cavity wherever penetration of this cavity by gunshot is suspected; while the military surgeon, having in view the frequent recovery of such cases when treated expectantly, and knowing the almost absolute certainty of producing infection under the conditions which obtain in field hospitals, does not usually resort to laparotomy unless death without operation may be considered certain.

While the conditions incident to environment are practically similar for all classes of wounds received in war, in that all are received in the field and have to be treated under the restrictions imposed by the location and the supplies at hand, the traumatisms themselves may be divided into two great classes, in accordance with

the weapons by which they are inflicted. This division arises from the fact that one class of wounds, and that comprising the greater number, is characterized by peculiarity of form, complication, and course of healing, while the other class does not differ markedly from the traumatisms often observed in civil life.

To the first class belong all bullet wounds; first, those made by the small caliber compound bullet; and second, those made by revolver and shrapnel bullets. Of this class those made by rifle-bullets are the most important, as they are by far the most numerous, and as they produce traumatisms having special characteristics.

To the second class belong all wounds made by missiles of large caliber, by fragments of shell, by indirect missiles, by bayonet, lance, saber, or like cutting or puncturing weapons. The wounds of this class furnish the minority of cases and are all characterized by being more or less lacerated, or by having a considerable extent of skin-surface involved and of being almost invariably infected, thus necessitating their being treated as infected wounds and by the open antiseptic method. The comparative infrequency of this class of cases is shown by the following table, in which the percentage of wounds inflicted by small arms, artillery, and side arms, is given for four recent wars:

TABLE I.—PERCENTAGE OF WOUNDS BY DIFFERENT ARMS.

WARS.	SMALL ARMS (percent).	ARTILLERY (percent).	SIDE ARMS (percent).
American Civil ¹	90.1	9.8	0.37
Franco-German ²	94	4.7	1.3
China-Japan, Third Division, Second Army Corps ³	90.8	7.6	1.5
Spanish-American (U.S. Regu- lars) ⁴	92.2	7.8	0.0

It may therefore be estimated that considerably more than 90% of all wounds in war are inflicted by rifle bullets. This proportion will vary in different engagements. In siege operations and in attacks on fortifications the percentage of wounds from artillery fire will be above the average, as in the storming of Paris, where 36% of the German loss was from this cause (Rawitz). On the other hand, in general engagements the wounds from artillery fire and side arms will be few and nearly all the casualties will be due to rifle fire, as in the battle of Colenso in the Anglo-Boer war, where 97.5% of the wounds were due to rifle fire and but 2.5% to shell injuries. For this reason consideration of the ballistics of the modern military rifle in relation to the traumatisms produced by it is of the greatest importance.

THE MODERN MILITARY RIFLE.

The modern military rifle is the result of the gradual evolution of firearms which has for its end greater precision, long range, greater penetration, flat trajectory, rapidity of fire, and small weight of ammunition. The result is a class of weapons all of which are practically identical in the particulars above named.

These rifles (Table II) weigh approximately from 8 to 10 pounds; are of magazine type, carrying from 5 to 12 rounds in the magazine; vary in caliber from 6.5 mm. to 8 mm., and use smokeless powder varying from 1.94 to 2.74 grams for each charge. The projectile is a compound bullet consisting of a lead or hard lead core swaged into a casing of cupro-nickel, or cupro-nickel

* The paper signed "Edro" was awarded the Sander prize (a gold medal) for the best paper on military surgery, submitted for competition at the annual meeting of the Association of Military Surgeons of the United States, held in New York City, May 31 to June 2, 1900. The committee of award consisted of Brig.-Gen. J. D. Griffith, Surg.-Gen. N. G. Mo., Medical Director Geo. W. Woods, U. S. Navy; and Major A. C. Girard, Surgeon U. S. Army, and all papers were submitted to the committee with their *nommes de plume* only.

steel. It (Figure 1: 1, 2) has a caliber of from 6.7 mm. to 8.19 mm.; a length of from 30 mm. to 31.8 mm.; a weight of 10.34 grams to 15.8 grams; and a muzzle velocity of from 1,968 to 2,395 feet per second.

FIG. 1.—Photograph of lodged, undeformed and deformed bullets removed from Spanish-American war cases; natural size. 1. Undeformed Krag-Jorgensen. 2. Undeformed Maunder. 3, 4, 5, 6. Maunder bullets deformed by ricochet. 7. Brass-jacketed Remington, caliber 42. 8. Shrapnel bullet, soft lead.

With this weapon and projectile the danger zone has been greatly increased, the range being practically point blank up to 600 yards, while the weapon is capable of inflicting a mortal wound up to a distance as great as 5,000 yards.

The compound bullet used with this weapon has 4 properties of great importance: (a) high velocity; (b) great section density; (c) cylindro-conoidal form; (d) great resistance to deforming violence. These properties combine to give it great penetrating power; while its velocity at the time of impact has a marked effect upon the amount and form of traumatism which it produces in animal tissues, and its velocity and resistance to deformation combined, make it much more liable to ricochet with sufficient violence to produce marked traumatisms even after violent ricochet impact.

Result of the Use of the Modern Small-Caliber Rifle.—Upon the adoption of the modern military rifle by different nations, much speculation was indulged in and many experiments were undertaken to determine its effectiveness as a weapon of war and the effect of its projectile upon the human body. Of these it may be said that the experiments of Demosthenes⁶ and of von Coler and Schjerning⁶ upon living animals at actual ranges were the most satisfactory.

But while these experiments gave in part the physical traumatic effects which might be expected of the compound bullet, the physiologic effects and the results from the standpoint of surgical therapeutics could only be determined by its use in actual war. These we now have as a result of experience in the Spanish-American war and reports from the Anglo-Boer war, so that we may now consider ourselves in position to act with intelligence and authority in this department of military surgery.

TABLE III.—SHOWING PROPORTION OF KILLED TO WOUNDED.

	KILLED.	WOUNDED.	RATIO.
With old smooth-bore weapons; Blenheim (1704) to Waterloo (1815) 13 great battles. ⁷	91,732	222,699	1 to 2.43
With improved rifled breech-loading weapons; Crimea (1856) to Liizaine (1871) 23 great battles. ⁷	81,831	322,171	1 to 3.96
With modern small-caliber rifle; Spanish-American War. ⁸	.280	1,577	1 to 5.6
Anglo-Boer War up to February 17, 1900. ⁹	1,407	5,303	1 to 3.7

Reports from the Anglo-Boer War up to the present writing indicate that the ratio of killed to wounded, 1 to 3.7, is fully equal to that of the older weapons; the average since the adoption of rifled arms being 1 to 3.96. The ratio of killed to wounded was somewhat lower in the Spanish-American War, being 1 to 5.7, but this was undoubtedly due to the long range at which much of the fighting was done. Different wars, like different battles, will give a different ratio of killed to wounded; the difference being due, not only to the form of weapon used but to the terrain, methods of attack and defence, and many other factors. Thus in the American Civil War the ratio was 1 to 4.7, while in the Turko-Russian

War, in which practically similar weapons were used, the ratio in the Russian Army was 1 to 2.01, and in some battles the killed even exceeded the wounded in number. The conclusion reached, therefore, is that *as many deaths upon the battlefield may be expected from the use of the modern small-caliber rifle as from the older fire-arms.*

Far different, however, is the mortality of the wounded. The percentage of the wounded who die has been greatly reduced since the adoption of the small-caliber rifle.

TABLE IV.—NUMBER OF WOUNDED, NUMBER DIED OF WOUNDS, AND PERCENTAGE OF RECOVERIES AND DEATHS AMONG THE WOUNDED IN RECENT WARS.

¹ Statistics from *British Medical Journal* of March 3, 1900.

This great percentage of recoveries of the wounded is due to two factors: (a) the treatment of the wounds by modern aseptic and antiseptic methods; and (b) the peculiarities of the traumatisms produced by the small-caliber compound bullet. The wounds produced by this missile are usually either almost immediately fatal or of such character as to make the probability of recovery very great except in the case of wounds of certain regions or organs, as will be pointed out hereafter.

THE TRAUMATISMS PRODUCED BY THE UNDEFORMED COMPOUND BULLET.—The character of the traumatisms from the compound bullet varies with (a) the velocity of the bullet at the time of impact, and (b) with the structures of the tissue wounded.

With certain tissues, skin, muscle, fascia and adipose tissue, its effect is practically identical at all ranges. It perforates these tissues cleanly and directly, cutting whatever lies in its way, be it artery, vein or nerve. The spongy bones, as those of the face, carpus, metacarpus, and epiphyses of long bones in young subjects, or bones softened by disease, it generally perforates cleanly or with little shattering, at all ranges.

Upon the shafts of long bones or bones composed of compact tissue, upon organs with fluid contents (stomach, intestines, bladder,) and organs of spongy texture containing large quantities of fluid (brain, liver, spleen, kidneys,) the compound bullet at long range produces its minimum amount of traumatism, *but in these tissues and organs the destructive effect of the bullet increases in proportion to the shortness of the range until, at about 600 yards and under, it will smash the shaft of a femur or a humerus to fragments,¹⁰ and upon the brain, liver, kidneys, spleen or stomach, unless the latter is empty, will act practically with explosive violence.*

From this wide difference in the traumatic effects produced by the compound bullet it is easy to understand

why the wounds made by it are so frequently immediately fatal, or, on the other hand, give such excellent opportunity for recovery.

Much has been written of the so-called *explosive effect* of this bullet, and this effect is of the greatest importance. It means simply the results of the lateral transmission of energy imparted to the tissues by the rapidly moving missile. If energy were transmitted only in a line directly in front of a bullet, the bullet would make clean-cut perforations in all organs or tissues through which it passed and immediate fatal results would arise only from direct wounds of bloodvessels, perforations of the heart, or impingement of the bullet upon some vital part of the central nervous system. Lateral transmission of energy, therefore, is a factor of the greatest importance, for the majority of severe traumatisms and immediately fatal effects are due to it.

This transmission of energy to an extent sufficient to cause extensive solutions of continuity occurs to marked extent only in certain organs and tissues and in these only when the velocity of the missile is great.

As this destructive effect occurs only in certain organs and tissues, it must follow that it is because these best transmit the energy imparted by the bullet; and as the structures which transmit this energy with trauma-producing violence are either compact bone or organs containing fluid, or those practically saturated with fluid, it seems most probable that this energy is transmitted in two ways: either through the transmission of vibration by the closely-knit, compact bone-tissue or through the incompressible fluid in fluid-saturated or fluid-containing organs. In compact bone, with the missile at high velocity, by the suddenness of the shock, the bone is disrupted, and the osseous particles, acting as secondary missiles, are forced outward, increasing the disruption and traumatism by lateral transmission of the energy imparted.

In fluid-containing organs or fluid-saturated organs, the impact of the bullet when at high velocity is so sudden and violent that its energy is transmitted in all directions by the molecules of the incompressible fluid and disruption in all directions occurs.

With the bullet moving at lower velocity the shock in bone or organ is less, the disruption consequently less, and with still lower velocity the ball may enter and pass through the same tissue or organ with practically no lateral destructive effect. In a broad way the result may be likened to the difference in effect produced by throwing a bullet into water contained in an open leaden vessel or firing it into it. In the first case the bullet will enter, making slight commotion and that mainly upon the surface of the water, while if the bullet is fired into the water, the containing vessel, even though open at the top, will be completely destroyed through the lateral transmission of energy by the incompressible fluid. (Figure 2.)

The penetrating and perforating wounds made by the small-caliber bullet are seldom infected.

The aseptic quality of these wounds was noted by Senn¹² in the Cuban campaign, who called attention to the necessity for, and value of, immediate protection of the wound, in order to prevent infection.

Foreign material or pieces of clothing are rarely carried into the wound, and when carried in are usually so small in amount that if they produce suppuration it is generally superficial.

According to Makin¹³ the frequency with which portions of clothing are carried into the wound depends

considerably upon the material. In khaki, from its hardness, the bullet generally makes a clean slit, but loss of substance from a flannel shirt or the Highland kilt is more common.

Effect of the Compound Bullet on the Soft Parts other than Fluid-containing and Fluid-saturated Organs.—In these tissues, as before stated, the bullet produces but little damage, the lesion being mainly confined to the line of

FIG. 2.—Showing effect produced by firing into a leaden vessel open at the top and containing water.—Stephenson.¹¹

its course. The skin, connective tissues, adipose tissue and muscle, from their loose and open structure and from not being fluid-saturated, transmit lateral impulses but feebly and consequently escape the extensive traumatic effect produced in dense bone and fluid-containing or fluid-saturated organs when the bullet is at high velocity.

The entrance and exit wounds made by the compound bullet are quite small and very similar in appearance. They are generally circular in shape, are usually from 0.75 to 1.25 centimeters in diameter and are usually slightly depressed and covered with a black scab. (Figure 3.)

In some cases, after a few days, the edges of the wound have the appearance of slight superficial necrosis or infection.¹⁴ When the bullet enters quite obliquely, the wound of entrance is generally oval in outline. In some cases the wound of exit is slightly lacerated or is slit-like, and heals with a scar difficult to detect.¹⁵ With the old, slow moving, lead bullet, the exit wound was generally much larger and much more lacerated than that of entrance, but with the modern compound bullet the wounds are so similar that it is frequently difficult to determine by which the bullet entered. Under an antiseptic dressing the wounds, unless infected, heal within a week or ten days without suppuration.

The course of the bullet and consequently the track of the wound is almost invariably in a straight line. When undeformed, the bullet is rarely deflected from its course, even by bone.

The track of uncomplicated flesh-wounds heals readily, but, according to Makin,¹³ the resulting cicatrix in the deeper parts of the wound is often of extreme density and may produce impairment of the function of a limb by involving tendons or tying the whole thickness of the traversed muscular structures together. This report of Makin is made early after the healing of these wounds and it is probable that in the majority of these cases muscular exercise will cause yielding of the cicatricial bands as it does in cases of subcutaneous cicatricial formation following deep-seated abscesses.

Bloodvessels and nerves are easily cut or severed by the compound bullet. The comparatively slow-moving lead bullet formerly used, frequently showed these structures aside and passed them without severing or

wounding them. With the small-caliber bullet the case is entirely different. From its high velocity, this missile does not slip by these structures, but severs, perforates or makes clean-cut lateral wounds. Undoubtedly one of the causes for the immediate high mortality among those struck by the compound bullet is from wounds of bloodvessels. The necessity for the immediate arrest of hemorrhage in wounds of important arteries by the compound bullet is apparent, for from the clean-cut nature of the wounds, bleeding is bound to be rapid and profuse, and first aid upon the firing line should be practised to the greatest extent possible under the conditions which obtain there. Relative to this proneness of the compound bullet to wound the bloodvessels, Treves,¹⁶ speaking of his experience in the Anglo-Boer war, remarks upon the number of traumatic aneurysms which have come under his observation and states that he has seen aneurysms of this variety of the brachial, femoral, popliteal and posterior tibial arteries, several varicose aneurysms of the thigh and an aneurysmal varix in Scarpa's triangle. In a case of large arterio-venous aneurysm in Hunter's canal with great swelling of the thigh he placed a temporary ligature on the common femoral, opened the sac, discovered the holes in the artery and vein, and ligated the artery above and below the wound and the vein on the proximal side only. Before the incision was closed the temporary ligature was removed. The case did well.

It is evident that wounds complicated by injury to bloodvessels will frequently have to be dealt with by

FIG. 3.—Entrance and exit wounds by Mauser bullets. 1. J. M., Private 1st Vol. Cav., entrance left cheek; exit right side of neck; range 200 yards; recovery. 2. H. B., Private 6th U. S. Infantry, entrance right breast; exit back, 1 inch to right of spine; traumatic pneumonia; recovery. Photographed by E. J. Meyer, Acting Assistant Surgeon, U. S. A., at U. S. A. General Hospital, Fort Monroe, Va., and reported by him to the Surgeon-General, U. S. Army.

military surgeons, and that ligation of the vessels under aseptic precautions will be indicated and will be followed by excellent results.

Secondary hemorrhage, however, will be rarely met with, as this complication is so frequently due to infection, a condition which will be much less common than formerly both from the generally aseptic nature of the wounds made by the modern bullet and from the fact that infection, when it does occur, is now generally readily controlled by antiseptic methods.

Wounds of the nerves will also be a frequent complica-

FIG. 4.—Multiple wounds. From photographs by Edward J. Meyer, Acting Assistant Surgeon, U. S. Army. 1. J. A., private, Co. H., 16th Infantry; missile passed through thigh and lodged in penis. 2. J. D., private, 6th Infantry; multiple wounds both thighs.

tion of wounds by the small-caliber bullet as well as will traumatic neuritis due to involvement of nerves in resulting cicatrices, or to degenerative changes set up in the nerve by traumatic injury. Dent¹⁷ gives several interesting cases of neuritis which came under his observation in the hospitals at Toynberg, Cape Colony. He relates a case in which pain, hyperesthesia and paralysis led to operative exposure of the ulnar nerve to relieve it from suspected cicatricial involvement, but the cicatricial track of the missile was seen to involve neither the nerve nor any of its branches. He instances other cases in which the nerve was not severed, yet distinct symptoms supervened. He concludes that from the high velocity of the bullet it may entail what the Germans call a violent *Erschütterung* of the nerve-trunk by passing in its immediate vicinity without directly wounding the nerve, but leading to rapid degenerative change and referred neuritis.

In cases in which the symptoms are due to involvement of a nerve in the cicatrix, operation under aseptic precautions will be indicated, and by liberating the nerve, improvement may follow, as in a case cited by the same writer. Where important nerves are severed they should be sutured by one of the methods used for this purpose, in order if possible to prevent paralysis of the parts distal to the traumatism.

Multiple wounds from the great penetrating power of the small-caliber bullet are common, as for instance the arm and forearm, the elbow being flexed; or the bullet may pass from side through the arm or chest or through both thighs (Figure 4).

In the case of multiple wounds by the same missile, the second wound of entrance is sometimes larger than the first and is more likely to be slightly infected, probably from infection of the bullet by passing twice through the skin and through several layers of clothing. That the compound bullet does not always become infected in this manner and that it is not extremely liable to become infected under such circumstances, is shown by a case which came under my personal observation,

that of Lieut. W. C. S., 6th U. S. Cavalry, in which the bullet passed through the body of a man standing in front of that officer and then passed through his arm and chest. Symptoms of lung-involvement appeared, but there was no infection of any of the wounds and the officer returned to duty in a few days.

EFFECT OF THE COMPOUND BULLET ON BONES.—In fractures of the bones by rifle bullets, the extent of the fracture, its form, and the amount of comminution are governed: (a) by the part of the bone struck; (b) by the velocity of the missile; and (c) by the angle of incidence. As all these factors can hardly be identical in any two cases, bone-lesions are bound to vary within certain limits. Of principal importance in these factors is the part of the bone struck, especially when the velocity of the missile is great. The physical qualities of the cancellous tissue of the epiphyses are so different from those of the compact tissue of the shaft of the long bones that, under conditions of violent impact, different traumatic results occur according to whether one or the other of these parts are struck.

FRACTURES OF THE DIAPHYSES OF LONG BONES.—When the shaft of a bone is struck at short range extensive comminution is produced, whatever the angle at which the bullet may impinge against the bone. The bullet in these cases produces an explosive effect in accordance with the reasons already given (Figure 5).

This effect is not confined to the bone alone; the bone-fragments driven out into the surrounding tissues act as secondary missiles, produce extensive traumatism of the subcutaneous soft parts and may even be driven out through the wound of exit and into a neighboring limb. In a case of this sort which came under the observation of the writer, the shaft of the femur was shattered for 5 inches of its length and largely reduced to bone-sand. The bullet passed through both thigh and leg, and on examining the wound in the latter, bone-

FIG. 5.—Lateral transmission of energy in the shaft of a long bone. Diagrammatic, modified from Beyer. A similar effect is produced in fluid-containing and fluid-saturated organs.

sand and several fragments of bone were found which had been carried through the first wound of exit and driven into the second wound of entrance by the force of the missile.

In another case the whole of the distal part of a meta-

carpal bone was blown out through the exit wound which was but little larger than usual (Figure 6).

This lateral transmission of energy by compact osse-

FIG. 6.—Radiograph showing explosive effect. The distal part of the fourth metacarpal entirely destroyed by a Mauser bullet (short range).

ous tissue is so great that a bone may be shattered by a bullet which barely grazes it. This is shown in Figure 7, from one of my cases. In this case the passage of a

FIG. 7.—Radiograph showing comminution of the radius by a Mauser bullet (high velocity) which barely grazed the bone.

Mauser bullet at high velocity across the front of the wrist cut nearly all the flexor tendons and though

merely grazing the radius shattered it completely. (Figure 7.) The same effect is seen in "gutter" wounds of the skull and will be treated of under wounds of the head.

This shattering effect decreases with the velocity of the bullet until it appears only where the angle of incidence is perpendicular to the shaft and the impact of the bullet is median. In cases where these factors are present, marked comminution may occur even when the velocity of the bullet is considerably reduced.

This is illustrated in Figure 8, which shows comminution of the femur the result of the passage of a bullet directly through it from before backward, the range being something over 600 yards.

FIG. 8.—Radiograph showing comminuted fracture of femur from median perpendicular impact of bullet; mid-range.

Cape Town Hospital Foul.—Rudyard Kipling, testifying before the South African Hospital Inquiry Commission August 1, said he found little fault generally, except with the Woodstock Hospital at Cape Town, which was horribly foul.

TRANSMISSION OF TUBERCULOSIS THROUGH THE MEAT AND MILK-SUPPLY.*

By JOHN J. REPP, V.M.D.,

of Ames, Iowa.

Professor of Pathology and Therapeutics, and Veterinarian to the Experiment Station, Iowa State College.

It is not long since the matter of transmission of tuberculosis through meat and milk was apparently settled, and the discussion of the subject was not considered of much importance. But within the past two or three years so much has been said and written upon this question both by those who by their knowledge of the subject are warranted in expressing themselves and by those not so warranted, principally the latter, that much scepticism has arisen, in consequence of which the subject has again been brought prominently before the public and its discussion has become a matter of vital importance. Whether the reason for this revival of the question has been a good one or not, I shall attempt to discover by reviewing the knowledge we possess on the subject. No amount of heated talk and speculative rehearsal will aid the solution of the problem in the minds of those who have been trained to think and to reason. Nothing but cold facts and logical inductions and deductions will suffice for these. It is my desire to view this subject from a plane on which nothing but facts and reason shall have position.

For the sake of clearness the subject may be treated under two general subdivisions, viz: (1) Transmission to Animals, and (2) Transmission to Man.

The meat and the milk of the bovine species only shall be considered.

I.—Transmission to Animals.

A. BY MEAT.

The portions of the body not commonly used for food, such as the brain, large lymphatic glands, spleen, bladder, uterus, lungs, testicles, mammary gland, skin, shall be excluded. The tongue, muscles, small intermuscular lymphatic glands, digestive tube, liver and kidneys are included.

No reference will be made to experiments in which the material inoculated or fed is not such as we have chosen to consider, or in which the character of material is not stated, of which classes there are a great many experiments which by their positive results demonstrate that tuberculosis can be transmitted from animal to animal of the same or of a different species.

1. By Artificial Methods.

Arloing¹ inoculated the muscle-juice of ten tuberculous cows into guineapigs and the result showed that the muscle-juice of two of the cows was infecting, 3 out of 10 guineapigs, 30%, inoculated from these two cows becoming tuberculous.

Galtier² infected two rabbits with the juice of the flesh of a tuberculous cow. It is noteworthy that two calves and two pigs fed on flesh from the same cow did not contract the disease.

Nocard³ produced tuberculosis in 1 case out of 21, 5%, by injecting juice of the flesh of 21 cows condemned at the abattoirs on account of tuberculosis.

Woodhead⁴ produced tuberculosis by injecting into the peritoneal cavity of two rabbits the raw juice from

the intercostal muscles of a tuberculous cow, after the tuberculous pleura had been stripped off.

Veyssi re and Humbert⁵ inoculated two rabbits with 1 cc. of flesh-juice from a tuberculous cow in very good condition, and both became tuberculous, 100%.

As closely related and perhaps directly concerned it may be asserted that Bang⁶ found the blood of 2 out of 20 highly tuberculous cows infecting when inoculated, 10%.

Several experimenters got entirely negative results from inoculation with the blood of tuberculous cattle.

2. By Natural Methods.

Nocard⁷ failed to produce tuberculosis in any of several litters of kittens which he fed with meat of cattle condemned on account of tuberculosis.

Perroncito⁸ had like negative results in case of 18 young pigs fed from three to five months on the flesh of condemned cattle.

John ⁹ fed 35 animals with the raw flesh from animals attacked with tuberculosis and 8, or 22.5%, became tuberculous.

Gerlach¹⁰ fed 46 subjects in the same manner and 6, or 13.1%, contracted the disease.

Peuch¹¹ caused 2 young pigs to consume 5 pounds of raw flesh, without bone, in 10 days, and in 2 and 3 months respectively these animals presented discrete glandular tuberculosis, 100%.

In speaking of the transmission of tuberculosis to animals through meat we must not lose sight of the fact that in the process of removal of the tubercular organs not ordinarily used as food, and which are for this reason not considered here, and in the cutting up of the carcass, some of the food parts of the carcass may be smeared with material rich in tubercle-bacilli. Such contaminated meat would of course be much more highly infectious. It is also to be noted that the muscles of swine and their intermuscular lymph-glands are more apt to be tuberculous than is the case with similar bovine structures. An examination of the literature to which I have had access indicates that but very little experimentation has been done to determine the infectiousness of those organs and tissues of tuberculous animals which are used for food. Much experimentation has been done with tissues other than food-tissues, but chiefly for the purpose of determining the general infectiousness of the disease. If these experiments with the food-tissues should be extended, there is no reason to doubt that they would indicate that this is a more extensive source of infection than is at present apparent. Also, none of the experiments cited, nor any other so far as I can learn, have been made with the liver as the object fed. German slaughter-house statistics¹² collected during 1888 and 1889 show that in all tuberculous cattle examined the liver showed the disease in 2% of cases. If a series of experiments were made by feeding this organ a much higher rate of infection would be observed. It will be noted that this is classed as a food-organ.

The experiments referred to nearly all have to do with the meat of highly tuberculous cattle. In these cases it is quite probable that the tubercle-bacillus was carried into the muscular system through the blood-vascular system, it being a well-recognized fact that in generalized tuberculosis the blood contains the microorganisms of the disease. It is quite unlikely that the food-organs and tissues in mild, localized cases would contain the bacillus, unless it might be the liver, with a possible rare occurrence in some of the other organs or tissues

* Read before the Iowa Tuberculosis Convention, Des Moines, Iowa, January 9, 1900.

under consideration. The food-organs or tissues of these mild cases ought not to be found infectious unless contaminated from nonfood organs or tissues in slaughtering or dressing. We have no evidence to show that the food-parts of these mild, localized cases would be unsafe for food-purposes if the nonfood organs and tissues and all tuberculous food-tissues were removed at the time of slaughter, provided that no contamination by smearing would take place.

It is well known that heating to a temperature of 158° F. and maintaining the temperature at this point for 15 minutes will devitalize the tubercle-bacillus. With this in view we are led to say that thorough cooking will render inert any tubercle-bacilli which may be in any way connected with a piece of meat. But the cooking must be so thorough as to subject the interior of the piece of meat to this heat for this length of time. Toussein¹³ found broiled steak infected after heating its interior to 176° F. It is presumed that he did not maintain this heat long enough. Woodhead¹⁴ found that rolls of meat weighing over 4 pounds which he had smeared with tuberculous matter were not sterilized by ordinary roasting and boiling.

John¹⁵ in 62 experiments administered notoriously tuberculous flesh after it had been submitted to cooking in boiling water for ten to fifteen minutes, and 35.5% of the animals became affected.

B. BY MILK.

This will be understood to mean milk and all of its products, as: skim-milk, buttermilk, cream, butter, cheese. The right is reserved to refer to any of these products as milk. The number of experiments and observations showing that tuberculosis may be transmitted from animal to animal of the same or different species through the medium of the milk of tuberculous cows is very great. In order to reinforce the assertion by the facts in the case a number of experiments and observations will be presented.

1. By Artificial Methods.

There is no attempt made in the following presentation to separate the experiments made with milk of cows with healthy udders from those made with the milk of cows with diseased udders, but attention is invited to the fact that the milk of cows with healthy udders is in a large number of cases infectious for animals.

Ernst¹⁶ reports that out of 88 guineapigs inoculated from 15 cows, 12, 13.6%, became tuberculous; of 90 rabbits, 6, 6.6%, became tuberculous.

Hirshberger¹⁷ produced tuberculosis in 14 out of a number of rabbits inoculated with the milk of 29 tuberculous cows with sound udders.

Bang¹⁸ by inoculation of guineapigs and rabbits found the milk of 9 out of 63 cows with apparently healthy udders infectious. On microscopic examination post-mortem 3 of these cows showed slight udder lesions.

Peuch¹⁹ produced tuberculosis in all 4 rabbits inoculated from the milk of a cow with tuberculous udder. A two-months-old pig fed five days with 4½ quarts of milk from the same udder did not show any lesions of tuberculosis when killed 56 days later.

Ravenel²⁰ experimented as follows: Five grade cows which did not show udder infection were selected and 10 cc. of the milk of each was at different times inoculated into the peritoneal cavity of 88 guineapigs, of which 11, 12.5%, became tuberculous. No preparation of the milk was made, but it was taken just as it came

from the cow. In another series of 52 guineapigs given the whole unprepared milk of the entire herd of 5 cows no tuberculosis developed.

Russell²¹ inoculated 17 guineapigs with 0.5 cc. to 4.0 cc. of milk of 7 different tuberculous cows only 1 of which showed tuberculosis of the udder. The 2, 11.8%, of these 17 guineapigs which were inoculated with the milk of the cow with tuberculous udder developed well-marked tuberculosis, although only 2.0 cc. and 1.0 cc., respectively, of milk was used.

Delépine²² injected the sediment obtained by centrifugation of 36 samples of country and town dairies into the subcutaneous tissues or the peritoneal cavity of 65 guineapigs and produced tuberculosis in 1 of them, 0.15%.

Schroeder²³ inoculated 40 guineapigs with the sediment resulting from centrifugalizing 19 samples of dairy and dealers' milk. Four died of intercurrent disease, and out of the 36 remaining 1 developed tuberculosis, 0.28%. Nothing is known of the cows from which the milk was obtained. In another series 32 guineapigs were inoculated intraperitoneally with centrifugalized milk of 15 cows either known to be tuberculous or which gave a tuberculin-reaction. Of these 1 developed tuberculosis, 0.3%. In still another series the centrifugalized or untreated milk of 4 cows whose udders were not diseased was injected into 16 guineapigs, each receiving intraperitoneally 5 doses on as many different dates. None of them developed tuberculosis.

Bollinger²⁴ produced tuberculosis in experimental animals with the milk of a cow with tuberculous udder, also with the milk of a cow with nontuberculous udder.

May²⁵ injected the milk of 6 cows, 1 of which had a tuberculous udder, and found the milk of the tuberculous udder infectious.

Stein²⁶ obtained by the same method 4 positive results out of 14 injections with milk from sound udders, 28.57%.

Nocard²⁷ inoculated the milk of 54 cows and obtained infection with 3 which had diseased udders.

Kanthack and Sladen,²⁸ in examining 16 sources of the milk-supply to the colleges in Cambridge, England, inoculated 80 guineapigs with the result that 23, or 25.55%, died of tuberculosis. Of these 23, 13 were inoculated from the creamy layer and 10 from the sediment. Of the 16 dairies examined 9 were infectious, 56.25%.

The Director of the Jenner Institute of Preventive Medicine²⁹ found by animal inoculation that the milk of 17 out of 100 samples was able to produce tuberculosis, 17%.

Adami³⁰ reports that he and Martin, in inoculating the milk from 10 tuberculous cows whose udders were free from tuberculosis, produced tuberculosis in 2 guineapigs out of 29 guineapigs and 26 rabbits inoculated intraperitoneally, 3.6%. A calf fed 5 months with the milk of the cow that produced the disease in these 2 guineapigs did not develop the disease.

The work of Rabinowitch and Kempner³¹ is very interesting as adding strong evidence to that already obtained of infectiousness of milk of tuberculous cows, even though the udder be sound. The experimenters used the milk of 15 cows which had reacted to the tuberculin test, in 10 of which the milk was found by inoculation of guineapigs to be infectious, 66.3%. Of the 10 cows 1 showed clinical evidence of udder tuberculosis and another showed it on microscopic examination post-mortem. Two other cows were only slightly affected as

determined by clinical examination, and still two others showed no symptoms of the disease. The inoculations were made into the peritoneal cavity with a combination of the sediment, obtained by centrifuging, and the fat layer. Butter was made from the milk of 1 of these 10 cows, and by inoculating guineapigs with it tuberculosis was set up in 3 out of 4 guineapigs inoculated, 75%.

Obermüller³² reports that Brusaferro has obtained positive results with 9 samples of butter; Bang from 1 specimen from a tuberculous cow; Roth from 2 out of 20 samples from diseased cows and from the market. He also reports that as a result of his own experiments he succeeded in producing tuberculosis in 4 out of 41 guineapigs inoculated from 10 different samples of butter.

2. By Natural Methods.

Bang³³ reports autopsy on 34 milk-fed calves, 24, 70.6%, of which showed lesions of tuberculosis evidently produced by the ingestion of milk containing tubercle-bacilli. Since then this author has made numerous similar observations.³⁴

Law³⁵ fed 3 calves of healthy parents on the milk of 3 tuberculous cows with apparently sound udders with the result of producing tuberculosis in all 3 calves, 100%.

Ernst³⁶ fed 21 healthy calves on milk of tuberculous cows with healthy udders and 8, 38%, of them became tuberculous.

Ernst³⁶ fed 48 rabbits from one to three months on the milk of healthy udders, and 2, 4.1%, were infected with tuberculosis.

Bang³⁹ says, "In Denmark, the swine are almost always fed with skim-milk, buttermilk, and whey, in addition to grain, and formerly it was noticed that when these milk-foods were given raw the swine almost always suffered from tuberculosis, where this disease was prevalent among cows. Since attention has been directed to this danger, tuberculosis in swine has greatly diminished in my country."

Hills and Rich⁴⁰ record the observation made by one of them that 5 swine, born of apparently healthy parents, and fed on skim-milk from a creamery partly supplied by tuberculous cows, were found tuberculous on autopsy. Also that many of the pigs fed on the milk of a herd of 91 cattle, 78 of which were tuberculous, were found tuberculous on postmortem examination.

Russell⁴¹ fed 2 pigs, beginning at six weeks of age, from August 23 to November 10, on separator slime received from the college creamery. None of them became tuberculous.

Bang⁴² says: "In Denmark milk is often given to young or to sick horses, and in those parts of the country where this custom is frequent, tuberculosis is not rare in the horse."

McFadyean⁴³ says: "In a considerable proportion of cases there was a distinct history of the animal's having been fed with tuberculous milk. Now, when one reflects that certainly not one horse in several hundreds is at any period of its life fed on cow's milk, the frequency with which tuberculosis has been met with in horses that had been so fed becomes very striking."

The foregoing states briefly most of what has been carefully done and recorded by way of experimentation and observation to prove that tuberculosis is communicable to other animals through the medium of the milk and the food tissues and organs of tuberculous neat cattle. In addition there might be added other obser-

vations of less definite shape, but no less true and convincing, as for example, the great lessening of tuberculosis among calves of tuberculous dams which are separated at birth and fed on sterilized milk or the milk of sound cows, as has been so abundantly shown by Bang in the prosecution of his suppressive measures in Denmark. Reference might also be made to numerous observations of veterinarians pointing to the transmission of tuberculosis from tuberculous cows through their milk to calves and swine. Enough has been done to prove beyond the peradventure of a doubt that tuberculosis may be transmitted through the milk and the food structures of tuberculous animals to the animals that consume these products or are inoculated with them. Upon this all students of the subject agree. This much has been proven. But these facts do not decide the important question at issue, viz.: whether or not tuberculosis is transmissible from animal to man, nor would they if they were multiplied *ad infinitum*. They only furnish a basis from which we may reason. For this purpose they are invaluable, as they establish the premise that the meat and milk of animals do at times contain living, virulent tubercle-bacilli.

II.—Transmission to Man.

A. BY MEAT.

1. By Artificial Methods.

There is no evidence of any sort on this point.

2. By Natural Methods.

The evidence on this score is only presumptive. However, it is well known that since ancient times legislation and sanitary regulations have been moulded around the presumption that the meat of highly tuberculous animals is dangerous as human food on account of the risk of conveying the disease to man through this medium. At this time every civilized nation that has any legislation or sanitary regulations in regard to the meat of tuberculous animals, provides that such meat shall either be condemned or that it shall be sold under declaration. These laws and regulations are based upon the analogy between tuberculosis in animals and the same disease in man and the fact of the intertransmissibility of this disease among the various species of animals. Whether this evidence warrants such restriction on the use of meat or not, has not yet been positively demonstrated, and on account of the impracticability of direct experiment with human beings we will almost certainly never be able to make such demonstration. The question must be decided upon the evidence we already have, and upon the additional evidence of the same character which from time to time may be added. The rarity of tuberculosis among the Jews who are so careful about their meat-inspection, and the high mortality from tuberculosis among certain North American Indians, referred to by Dr. Holden, who eat the various parts of diseased cattle raw, appear to indicate that there is danger of tuberculosis-infection of man from meat.

Of course, cooking of meats as it is usually practised effectually disposes of most of such danger as would exist if meat were eaten raw and without any attempt at sterilization. On the other hand there is not one whit of evidence that tuberculosis is not to some extent transmitted from animal to man through ingestion of meat. All the evidence we have indicates that such transmission occurs to a limited extent.

B. BY MILK.

1. *By Artificial Methods.*

No evidence.

2. *By Natural Methods.*

The evidence of transmission in this manner consists of recorded observations which have been made in case of human beings who have used the milk of tuberculous cows.

Olivier⁴⁴ reports that in a young ladies' boarding school 5 girls, the children of healthy parents, died of tuberculosis of the intestines. The cow which had for years supplied the school with milk was found to have generalized tuberculosis including the udder.

Two daughters of a Scotch family of good health who were brought up on milk of tuberculous cows died of tuberculosis. Two sons in the same family who did not use the milk remained healthy.⁴⁵

Stang⁴⁶ reports the case of a five-years-old boy of sound parentage and ancestry who died of tuberculosis. The cow whose milk this boy used was found badly tuberculous.

Deimne⁴⁷ reports the cases of four infants in the Children's Hospital at Berne, the offspring of sound parents, that died of intestinal and mesenteric tuberculosis. He was able to exclude all other sources of infection and to decide that they had been infected by the ingestion of the milk of tuberculous cows.

Hills⁴⁸ mentions the case of a child 21 months old, of a friend of his, which drank the milk of a highly tuberculous cow for one week while on a visit to his uncle, and three months later this child died of intestinal tuberculosis. Other sources of infection could be excluded. A second child brought up on sterilized milk is still healthy.

Hills⁴⁹ also reports the death of a boy 4 years old at Yonkers, New York, from tubercular meningitis. The infection was traced to the milk of 2 cows of whose milk this boy had drunk and which proved on autopsy to be tuberculous.

Ernst⁵⁰ reports the death of 3 children of one family from tuberculosis. These children had used the milk of a cow which later died of advanced tuberculosis including the udder.

Stalker and Niles⁵¹ report that 5 persons between 20 and 30 years of age of healthy ancestry died of tuberculosis within a period of two years. On the farm where these deaths occurred they found 17 cattle suffering from tuberculosis and other cattle had previously died of this disease.

Leonhardt⁵² reports the death from tuberculosis of the meninges, intestines, and mesentery of 2 children fed on milk of a tuberculous cow.

Sontag⁵³ reports the case of a six-months-old child of healthy parents which died of tuberculosis and which had been fed on the milk of a tuberculous cow.

Hernsdorf⁵⁴ has reported the case of a child dead of intestinal tuberculosis which had been fed on the milk of a tuberculous cow.

Rich⁵⁵ reports that a young man of healthy parents who died of tuberculosis had used plentifully of the milk of a herd of 74 cattle, 65 of which were tuberculous, some of them markedly so. Also, another young man died of tuberculosis. Two months later Rich destroyed 80 cattle out of the herd of the family, that is, about 90% of the entire herd. Also, a young woman died of tuberculosis, and a month later the cow whose milk she had used died of advanced tuberculosis.

Thorne⁵⁶ reports that 22 physicians out of 339 practicing in Ohio replied in the affirmative to the question, "Have you been able to trace any cases of tubercular disease to the milk of unhealthy cows?" and that 33 replied affirmatively to the question, "Have you had reason to suspect the origin of tubercular disease in older children or adults to be in the milk- or meat-supply?"

This series of experiments and observations has been selected from literature with the greatest care. Any reports which appeared not to be well authenticated or of a doubtful nature have been excluded. Besides this mass of positive evidence there is much more, that, while not so positive, is not less convincing. It appears that the evidence collected by Thorne from physicians in Ohio is especially valuable, not only in itself, but because it indicates what might be learned by addressing the same series of questions to the physicians of all the States of the Union.

Still further corroborative evidence is offered in the fact that such great numbers of bottle-fed children die of abdominal tuberculosis, and in the fact that tuberculosis of adults is decreasing in many places while tuberculosis of infants and small children does not show this marked decrease and is, in fact, increasing. Death from tuberculosis in all its forms in England and Wales has decreased 39.1% in the past 35 years. The greater part of this diminution was in the lung forms of this disease; for the same period the intestinal form has decreased only 8.5%. It is noteworthy that in the same period the increase in abdominal tuberculosis in children under one year has been 27.7%. Northrup⁵⁷ and Still⁵⁸ have presented statistics of autopsy in children which show that the pulmonary form of the disease is most common; that is, that the pulmonary lesions are primary, thus refuting the conclusion of most other pathologists also based on autopsy. This difference of conclusion can hardly be accounted for except upon the supposition that it is due to a difference in judgment among pathologists as to what is a primary and what a secondary lesion. This is a point on which the pathologist must exercise great care. He must not in this connection overlook the fact that, even though the most marked lesions appear in the thoracic cavity, this does not exclude primary infection by way of the digestive tract, because, as is well known, the infective agent has easy channels of passage from the abdominal cavity into the thoracic cavity by way of the thoracic duct and the vena cava.

Theobald Smith⁵⁹ calls attention to this migration of the disease as having been observed by him and others (Spengler) experimentally. Even assuming the conclusions of Northrup and Still to be correct, although they are contrary to the opinions generally held, there is still left a large percentage of cases to be accounted for by intestinal infection, and enough to warrant the most earnest crusade against the source of such infection.

However, neither animal inoculation, with its unmistakable results so far as the animals themselves are concerned, nor the recorded observations of almost doubtless transmission to man through the milk and meat prove with the positiveness of a demonstration that tuberculosis is transmissible to man through the milk. Yet, to nearly all students of this subject this is convincing proof, and we find the results of it in the protective legislation which everywhere abounds.

We have still further and more valuable evidence both in fact and in reason.

Whether or not tuberculosis of animals is transmis-

sible to man depends upon whether or not the tubercle-bacillus of the animal species is *pathogenic* for man. If this could be demonstrated, we would have a positive proof that would be beyond all question. We know that the tubercle-bacillus of the bovine tribe exists in the meat and milk products of these animals in many cases where they are tuberculous, and we know that man consumes these products thus bearing the bacillus. Therefore, if the pathogenicity of this animal tubercle-bacillus for the human species can be proved, the question is no longer debatable. The following examples are offered to the reasoning mind for the value they possess. In my opinion they are capable of supplying the evidence we need.

Tscherming,⁶⁰ of Copenhagen, attended a veterinarian who had cut his finger in making a postmortem on a tuberculous cow. The wound healed, but there remained a swelling which soon ulcerated and refused to heal, so that the whole tumefied mass had to be cut out. The microscope revealed the distinct tuberculous process and the presence of the characteristically staining bacilli.

Pfeiffer⁶¹ attended, at Weimar, a veterinarian named Moses, 34 years old, of good constitution, and without hereditary disposition, who, in 1885, cut his right thumb deeply in making a postmortem on a tuberculous cow. The wound healed, but six months later the cicatrix still remained swollen, and in autumn, 1886, the man had pulmonary tuberculosis with bacilli in his sputa and death occurred in 2½ years after the wound. Postmortem revealed tuberculosis of the joint of the wounded thumb, and in the lungs extensive tubercles and vomicae.

Law⁶² reports that a young veterinary friend of his who was inoculated in the hand in opening a tuberculous cow, suffered from a tumefaction of the resulting cicatrix, with tubercle-bacilli.

Rich⁶³ reports that a man cut his finger on a spicule of bone while making a postmortem examination of tuberculous cows, and that in a few weeks he developed a tuberculous joint, and a few months later showed unmistakable signs of phthisis.

Ravenel⁶⁴ reports the case of a veterinarian who cut the knuckle of his finger while making a postmortem examination of a tuberculous cow. The wound healed badly, remained swollen, and showed decided tendency to ulcerate. Removal of the cicatricial mass was practised and the tissues sent to him for examination. They showed typical tubercular lesions, with giant-cell formation.

I am well acquainted with this case myself and believe it to be an undoubted case of direct transmission of tuberculosis from cow to man by inoculation. This veterinarian told me that he did not become alarmed about the wound on his finger until he noticed a swelling and tenderness of the lymphatic glands on the inside of the elbow.

Further evidence than this is not on record so far as I have been able to ascertain. Whatever our conclusions may be they must be drawn from this evidence together with some corroborative evidence of another character which will be referred to later on. Those who are in search of more convincing evidence of the pathogenicity of the bacillus of animal tuberculosis for man must be informed that it is not to be had without direct experimental inoculation or experimental feeding of members of the human species with tuberculous products of animals. That this is not likely to be done it

is needless to state. It is not impossible that some one may apply to tuberculosis experiments of the same nature as those described by Arning,⁶⁴ in which a criminal was inoculated with leprosy material. Certainly this sort of experimentation might be done in case of criminals, but such experimental work can never be done in case of children. Hence the relation between the milk of tuberculous cows and children will never be decided on any evidence so positive as this. So far as adults are concerned, will not some of those who hold such a firm belief in the noninfectiousness for man of meat and milk of tuberculous animals offer themselves as willing subjects for rational experimentation? On account of their attitude in this matter it would be unreasonable (to their minds) and to say the least unkind in them not to demonstrate to the world that their position is correct when it could so easily and so safely (in their opinion) be done. I seriously doubt if any of those who say there is but little danger, or but slight danger, of transmission of tuberculosis from animals to man through meat and milk would show the courage of their professed convictions by personally using as food the meat or the milk of animals known to be tuberculous, much less would they submit themselves for experimentation.

Adami⁶⁵ considers as doubtful the conclusion that there has been a causal relation between the milk used and the tuberculosis of the persons using it, or between the wounds received while making autopsies and the subsequent tuberculosis in cases such as those cited in this article. He bases his opinion on the fact of the impossibility of *total* exclusion of all other sources of infection. This nonexclusion of all other sources of infection has been construed by some whose judgments are not to be considered valuable as an argument against the transmissibility of tuberculosis from animal to man, but when a scientist like Adami is unwittingly misled into giving countenance to such sophistry it is time to call attention to it. One who puts forth such a statement as an argument does not realize the abyss of fatalism into which he would plunge science in all attempts at discovering the source of infection in case of any of the infectious diseases; especially would this be the case in such a chronic disease as tuberculosis. If the argument were valid, it would apply to all diseases. It is not possible to absolutely and totally exclude all other sources of infection in any case. To do this would demand on the part of the experimenter and observer a knowledge of all possible sources of infection, other than the one under consideration, that might be active in a given case; and further, a knowledge of altogether hidden and entirely unknown causes which might act. Unless this were done the same objection might be raised, viz: The other causes have not yet all been excluded: there may be some source of infection of which neither you, nor I, nor any one else has any knowledge. *Reductio ad absurdum!* All we can do, and all that it is necessary to do, is to exclude all known or probable sources. We must decide upon an anchorage somewhere which the light of scientific knowledge points out. If we have done this, and get positive results in a sufficient number of cases, we have a legitimate right to draw conclusions accordingly. In the cases referred to it is to be considered that we have practically excluded all other sources of infection. Science does not require that more be done.

Some work has been done to ascertain whether or not there is any difference of morphology, character of culture, or virulence between the tubercle-bacillus derived

from man and that derived from animals, with the hope of incidentally shedding some light on the question of the transmissibility of tuberculosis from animal to man. It was taught by the earlier investigators from Koch forward with few exceptions that the bacilli from these two sources were virtually similar. This belief was held and taught until the recent experiments of Smith,⁶⁶ Pearson,⁶⁷ and Dinwiddie⁶⁸ were made and which show that the bovine tubercle-bacillus is distinctly more virulent for the species of animals thus far experimented upon than is the human bacillus, with a few exceptions in which no difference in virulence was seen. Theobald Smith is probably the only one who has made a comparative study of the bacilli from the bovine and the human source in culture and under the microscope of sufficient extent to be of any value. He has noticed some points of difference, but none that so far as we know, have any bearing upon the question under consideration. It is true that if there is a marked difference between the bacilli from the two sources it may in time be found out that, by a careful study of the bacilli themselves, we shall be able to differentiate cases of human infection from cases of bovine infection in man by an examination of the respective bacilli. However this may be, such a stage has not yet been reached. It may be that the cultures of human bacilli which Smith studied were all made from cases of human infection, and that the bacilli were adapted to the human system for generations. If a study of human bacilli from a case of supposed bovine infection could be studied side by side with bovine bacilli, the differences which Smith found might not be present. This seems to be a fertile field for investigation. It is not unlikely that the bovine tubercle-bacillus, by passing through the bodies of several persons, or even one, may be so modified as to present under study the characters which we ascribe to the human bacillus. Weight is added to this opinion by the experiments of Nocard⁶⁹ in which he succeeded by means of cultures *in vivo* in transforming the human bacillus into one of the avian type.

Neither the work of Smith, Pearson, nor Dinwiddie adds or pretends to add anything positive to our knowledge of the transmissibility of tuberculosis from animal to man through the meat and milk. All evidence we have from this work is that afforded by an interpretation of the results and the use of them as a basis for reasoning about what the result would be if the terms of the experiment should be reversed and human beings were inoculated with bovine bacilli. By such an examination of these results we find that they are rightfully interpreted as antagonistic to the idea that tuberculosis is not communicated from animal to man through the meat and milk. Smith's experiments have, evidently because of careless reading, been used by some writers as proof of a nontransmissibility from the animal to the human being. On the contrary, Smith's experiments do not indicate this, nor does Smith claim that they do. This author says, after announcing his experiments, without any reference to these experiments, "It seems to me that, accepting the clinical evidence on hand, bovine tuberculosis may be transmitted to children when the body is overpowered by large numbers of bacilli, as in udder-tuberculosis, or where certain unknown favorable conditions exist." As to numbers of bacilli it may be said that they have been found in milk, even from nontuberculous udders, by microscopic examination. Only one drop can be examined at a time by the microscope. If there is but one bacillus in each drop there would be at

least 5,000 in a pint of milk, which is about the daily allowance for an infant. Whether or not Smith would consider this an overpowering number, he gives us no hint. What the "unknown favorable conditions" are is only to be surmised. Smith concludes his article by saying,⁷⁰ "if in this brief summary I have presented nothing but problems to be solved and doubts to be entertained, I feel quite," etc., thus indicating that he has proved nothing, but that he has only pointed the way toward the proper field of investigation, something he has certainly done. Dinwiddie does not touch upon these points.

Now, what is the evidence *against* belief of the transmissibility of tuberculosis from animal to man? There is no valid argument, no observation, no proof. Writing has been done which shows that a few people will climb over all the evidence which is presented here, and which is conclusive to most minds, apparently unable to appreciate it, and call for *direct* evidence, a demand which in its very essence betrays on the part of the person making it an unfamiliarity with the whole subject, and condemns him as, because of this unfamiliarity, disqualified to speak authoritatively on the subject. Those who continuously call for proof, which they are unable to recognize when given, and who give none in return in support of their own conclusions, are unworthy of reply.

The work of Smith, Pearson, and Dinwiddie already referred to, which points to the conclusion that the bovine tubercle-bacillus is more virulent⁷¹ for a number of species than the human tubercle-bacilli and equally virulent⁷² for others, certainly warrants us, if we draw any conclusion at all with reference to man, that the bovine tubercle-bacilli are more virulent for man also. The extreme susceptibility of man to tuberculosis, indicated by the large percentage of the human race suffering from the disease, would further point to the soundness of such a conclusion. Manifestly the opposite conclusion would be eminently unfair. It has been intimated by Conn⁷³ that "if the human bacillus is only slightly pathogenic for cattle it is at least likely that the bovine variety may not be very dangerous to man." What nonsense! It would be as reasonable to say that, inasmuch as the American soldiers who at one time during the Philippine War were armed with Springfield rifles which were of short range were not dangerous to the Filipinos, neither were the Filipinos, at that time armed with long range Mauser rifles, dangerous for the American soldiers.

I consider that there is another point worthy of notice. It is this: In the comparisons of the virulence of bovine and human tubercle-bacilli which have been made by Smith and Dinwiddie they have compared the bacilli of human *sputum* with the bacilli of bovine *tissues*. Now, especially in view of the fact that Smith has pointed out that he has observed the sputum bacilli to be more saprophytic in nature than the bovine bacilli which he examined, is it not probable that this is the case, and that the bacilli of human *tissues* may show themselves more parasitic in nature than the *sputum* bacilli, and of equal virulence with bovine bacilli from tissues? It seems to me that if we use tissue bacilli on the one hand, we should use them on the other. Pearson has done this in his experiments, as yet unpublished, as I happen to know because I assisted in instituting the work. However, even here many difficulties present themselves and many errors can creep in. Comparisons can be made with cultures only, and not with the tissues themselves for reasons which are apparent to all. This whole subject is one surrounded with difficulty.

It may be stated *en passant* that students of this subject of transmissibility of tuberculosis by meat and milk, whether they be individuals or commissions appointed to study the matter, are almost unanimous in their opinion that there is danger of such transmission, and that this danger is great enough to call forth protective legislation and regulation against these sources of danger. What evidence has brought them to such conclusion? Practically that which has been presented in this paper.

SUMMARY.

The evidence presented here is:

1. That tuberculosis may be transmitted to animals through their eating the meat of certain other animals which are tuberculous or by their being inoculated with it.
2. That tuberculosis may be transmitted to animals through their ingestion of the milk of certain cows which are tuberculous, or by their being inoculated with it, both when the udder of the cows is diseased and when it is healthy.
3. That, therefore, the meat and milk of certain tuberculous animals contain living, virulent tubercle-bacilli.
4. That the tubercle-bacilli of cattle are pathogenic for man.
5. That, therefore, the meat and milk of certain tuberculous animals is capable of producing tuberculosis in human beings who use these products as food.
6. That there is no evidence that the converse of these conclusions is true.

PRACTICAL CONCLUSIONS.

1. In Regard to Meat.

The meat of all food animals, especially cattle, is unfit for food when the animal is highly tuberculous; but is safe for food when the animal is only slightly or moderately tuberculous, especially so if the meat is well cooked, provided the tubercular tissues are eliminated.

2. In Regard to Milk.

a. The milk of a cow with tuberculous udder is always dangerous for food unless it is well sterilized.

b. The milk of tuberculous cows with healthy udders is sometimes dangerous for food unless well sterilized. We cannot tell except by experiment, which is impracticable as a routine matter, when such milk is dangerous and when it is not. Hence the milk of tuberculous cows without disease of the udder should always be looked upon with suspicion, and either not be used or be used only after sterilization.

c. Tuberculous cows may be kept for breeding purposes provided they are isolated, even from their own offspring, and their products sterilized before use; or,—

d. They may be slaughtered for food under conditions imposed by the conclusion stated above in regard to meat.

GENERAL CONCLUSION.

All legislation and regulation should favor the disposition of tuberculous animals as suggested above, so far as meat and milk are concerned.

MÜTTER LECTURES OF THE COLLEGE OF PHYSICIANS
OF PHILADELPHIA.The Surgical Treatment of Congenital and Pathologic
Disfigurements of the Face.

By JOHN B. ROBERTS, M.D.

Professor of Surgery in the Philadelphia Polyclinic.

LECTURE IX.—The Operative Treatment of Deformed or
Deficient Ears.

(Abstract.)

OPERATIONS for the relief of aural disfigurement have received very little attention until within the last six or eight years. This is rather remarkable because the deformities are quite conspicuous and the operations for their relief free from serious risk. It is the more strange because Italians of the time of Tagliacozzi and earlier did plastic operations upon the ear, and it is said by Szymanowski that such operations are mentioned in Sanscrit writings.

The ears of prize-fighters often receive injuries which result in permanent cicatricial deformity. Sexton called attention some years ago to the fact that the ancient Greeks must have been familiar with deformed ears in

boxers, because the characteristic disfigurement is, according to him, shown in statues representing ancient Greek pugilists.

The external ear is quite often the seat of incised and lacerated wounds which require accurate suturing to reproduce the normal outline. The auricle may be

FIG. 1.—Congenital deformity of ear, treated by elliptical incision and bending of the cartilage.

torn almost completely from the skull and yet be easily restored to its position by a few sutures. Completely detached portions should be cleansed and sutured into position, even if some time has elapsed since the accident. Union may sometimes be obtained even in these unfavorable cases.

Sloughing after frost-bite is a not unusual cause of aural disfigurement. Plastic operations may improve the appearance of the organ. A common injury is laceration of the lobule from earrings having been torn out of the ear by children, grasping at the trinket, while being carried by their mothers. The fissure so made may be easily closed, even if cicatrization has previously occurred, by freshening the edges of the cleft and applying sutures. I have operated when the ear has had several such cicatrized tears in its lobule. A similar plastic operation is necessary after the removal of the keloid growths that occasionally result after piercing the ears for earrings. A little ingenuity will greatly improve such cases, as I have proved in operating upon a good many patients.

Burns of the side of the head cause sloughing and cicatricial disfigurement. Pancoast many years ago made a new lobule to an ear by two crescentic incisions which enabled him to lift up sufficient tissue to construct a lobule.

A great loss of tissue from sloughing may need to be replaced by taking a flap from the hand, applied to the side of the head until circulation has been established. The tissue may then be cut from the hand. A large piece of tissue may be transferred from the abdomen. In such an operation the graft would first be attached to the hand, and two weeks later cut from the ab-

domen; and the hand would then be applied to the side of the head in such a way as to permit the new tissue to be attached to the region of the ear.

Irregularities of the auricle, enchondromatous nodules in the neighborhood of the ear, and fistulous openings occur as congenital defects. They are due to irregular coalescence of the branchial arches and imperfect closure of the branchial clefts. Sometimes there is a deficiency of cartilage in the pinna which allows the external ear to assume abnormal positions on account of its flaccid character. I recently operated upon the case of this sort which is shown in the figure. At other times the cartilage in the pinna may become buckled or bent during birth or soon afterwards, and asymmetrical ears result from want of correction of this abnormality. The lack of cartilaginous material may perhaps be compensated for by excising a portion of the skin back of the ear and stitching it to the side of the head. It has been suggested that a thin sheet of platinum or other material be inserted beneath the skin, to give rigidity and a proper contour to the external ear. This could perhaps be bent into shape, even after the tissues had healed over it. The deformity due to bending or buckling of the cartilage may be remedied, if the child is treated when young, by bending the organ in the opposite direction and holding it there by means of adhesive strips, or some form of spring going across the top of the head and having a pad to press upon the ear. If the deformity is slight, the contracting influence of collodion may be utilized.

Exceedingly large ears, due to a sort of hypertrophy of all the tissues, occasionally require curtailment. This may be done satisfactorily by excising a V-shaped portion of the auricle with the base of the V towards the outer margin of the organ. Careful suturing will restore the general outline and maintain the regularity of the natural elevations and depressions. The excision of a crescentic piece from the central part of the pinna, with a tongue-shaped process extending from the convex border of the crescent to the border of the pinna, makes a rather neater operation and restores more accurately the normal contour. This method was, I believe, first suggested by Dr. Parkhill. Such elephantine ears are greatly improved by these operations. Flaring or out-

FIG. 2.—Diagram of method of Parkhill for reducing size of ear. Dotted lines show piece to be excised.

standing ears are very ugly, especially when the flaring condition is associated with great size. Such ears may be brought closer to the head by the excision of an elliptical piece of tissue behind the auricle, and the in-

sertion of stitches so as to draw the cartilage nearer to the surface of the cranium. The elliptical portion removed should have its long diameter in the vertical direction and should be wide at the point where it is desired to draw the cartilage inward to the greatest extent. The portion removed should be quite large and its outer edge on the posterior surface of the pinna should extend far outwards as the amount of retraction desired is greater.

The inner border of the ellipse on the surface of the skull should be comparatively close to the bottom of the furrow between the ear and the head. By the insertion of stitches in an oblique direction the axis of the ear can be somewhat changed.

Some operators have removed only the skin and subcutaneous tissue; others have taken out the entire thickness of the pinna, including the cartilage and the skin on both the back and front. It is probably best to remove a large portion of skin and subcutaneous tissue on the posterior surface of the ear and the skull, and to excise a wedge-shaped portion of the cartilaginous structures; but the cartilaginous piece which is re-

FIG. 3.—Method suggested by Szymanowski for constructing an auricle in congenital absence of the external ear. A. Dotted lines show incisions by which the skin is raised and doubled so as to make a crude auricle. The posterior flap is thrust under the anterior one and sutured by through-and-through sutures. B. Shows incisions made at a subsequent operation to model the crude auricle into more perfect shape.

moved should be much narrower than that cut out of the skin. This method I have used satisfactorily. It is usually not necessary to carry the incision through the skin on the front of the ear.

Congenital absence of the ears may be treated by the adoption of an aluminum ear properly tinted and held in place by a spring inserted in a slit in the soft tissues. Westlake adapted such a contrivance to a man's head, and the patient was able to unlock the artificial organ and remove it. This was done by means of a spring situated behind the artificial ear.

Szymanowski has suggested the making of a cutaneous ear in these cases of congenital absence of the organ. The diagram shows the incisions for the reconstruction of a rudely shaped ear which is afterwards to be modelled by smaller incisions and proper suturing. It seems as if it might be possible to insert an aseptic piece of metal into such a cutaneous reconstruction to give it rigidity and a contour like that of an ear.

The Physiologic Action of Phenactin.—From an extensive study of the drug Horatio C. Wood, Jr. (*University Medical Magazine*, July, 1900) concludes as follows: 1. The moderate dose of phenacetin is without any distinct action on any vital organ. 2. Large doses lessen reflexes by a direct action on the spinal cord. 3. Doses of 0.5 gm. per kilo of body-weight (equivalent to a little less than one ounce for a 150-pound man) kill by arrest of respiration. 4. Doses even up to 0.5 gm. per kilo had no distinct effect on the circulation. [M.B.T.]

CLINICAL REPORT OF TWO CASES OF PARALYTIC DEMENTIA OCCURRING IN THE NEGRO.*

By W. K. WALKER, M.D.,

of Dixmont, Pa.,

First Assistant Physician to the Western Pennsylvania Hospital for the Insane.

I HAVE considered the following cases of sufficient interest to justify reporting at length, representing as they do a large and increasing proportion of patients today found in hospitals for the insane, but which, in the earliest and obscure stage of the disease must come under the notice of the general practitioner. They illustrate the two principal clinical types of paralytic dementia and are of further interest because found in a race which was practically exempt from this disease until emancipated and thus subjected to the manifold influences of civilization with its attendant evils. Today, because of greater indulgence in alcohol, increased frequency of syphilis and stress from greater psychic demands upon him, the negro is a frequent victim of this disease.

The first case under examination is one of uncomplicated paralytic dementia, *i. e.*, dementia and a progressive paralysis:

W. H., laborer, 35 years old, was admitted to the Western Pennsylvania Hospital for the Insane, March 1, 1900. Little can be learned of his family history, except that his mother has suffered from rheumatism all her life, and is now (at the age of 70) quite crippled from its results. The patient, nervous in boyhood, was taken from school at an early age because "the doctor said if he did not give up study he would go insane." Married at the age of 27, he is the father of 3 children; the eldest (a girl of 6 years) had convulsions during the period of teething. The patient freely acknowledges repeated attacks of gonorrhea but denies syphilis, and evidence that he has suffered from this disease can not be obtained. He has used tobacco freely, whisky continuously, and to excess since the age of 20. Previous to the onset of his present trouble his general health was good. Nine months ago he appeared to grow indifferent to his surroundings; became quiet and dull at home where he had previously been talkative and lively, and was easily irritated by the children. Heretofore industrious, he would leave his unfinished work and stand around in an absent-minded way. Gradually he became more stupid and dull until November (6 months after the first symptoms were noticed), when he complained of constant headache and could not sleep; since this time his memory has grown progressively worse. Sent to the store he would bring home useless articles, among them things which he could not well afford to buy. Upon one occasion he got a pair of shoes and attempted to leave the store without making arrangements to pay for them. Again, left at home to look after the children while his wife was at work, he killed a chicken and cooked it with no further preparation than removal of its feathers. He has difficulty in recalling the names of his children, and cannot remember their ages or his own. His appetite has been ravenous "never seems to get enough to eat;" he is obstinately constipated, has constant headache and sleeps but little. There has been no manifestation of violence; he is brought to the Hospital because he is such a care that his wife cannot look after him and at the same time make a living for her family. His wife states that his sexual appetite, previously manifested to an exaggerated degree, has been gradually lessening in the last 2 years, and for a month or more has practically been absent.

Upon examination he is found to be fairly well nourished, but with digestive functions imperfectly performed as evidenced in broad, flabby, and furred tongue. Heart: first sound weak, no murmurs. Pulse: irregular, frequency 86. No gross abnormality of any organ. Urine: dark amber in color, acid in reaction, specific gravity, 1.030, no albumin.

Station is good; gait slouching but not incoordinate. There

* Read before the Pittsburg Academy of Medicine, March 26, 1900.

is slight tremor of facial, manual and lingual muscles and incoordination of these upon effort to perform any complicated movement. Reflexes: Deep, are all exaggerated, more apparently upon the left side; ankle-clonus is present; the superficial are not markedly diminished. The cremasteric is plainly elicited. Dynamometer R. 95, L. 85.

Pupils are unequal—right 3 by 3 mm., left, $3\frac{1}{2}$ by $3\frac{1}{2}$ mm. The irids respond sluggishly to both light and accommodation. Ophthalmoscopic examination shows normal appearance of both optic discs.

The patient's manner is apathetic, but placid and good-natured. There is marked amnesia not only for names but for both recent and remote events. He is very feeble mentally and in a condition of dementia analogous in many ways to ordinary dementia; he has no delusions, however, nor is there marked condition of *bien-être*; at most a decided optimism manifest in the belief that he "can put \$500 in bank as the savings of next summer."

In Case 2 we have dementia and progressive paralysis with superadded insanity impressing upon the dementia certain special characteristics.

G. L., preacher, 55 years old, admitted May 2, 1899. No history was obtainable except that he had been traveling about the country collecting money for the purpose of founding a negro college in the West. Ten days previous to his admission he was found at midnight, preaching to an imaginary audience upon the streets of New Castle. Arrested and placed in the county jail, he became much excited, later raving, smashing the furniture of his cell to kindling wood and tearing his bed to shreds. He talked of great schemes for educating the negro; intended preaching in the opera house, and would in this way collect millions for the purpose. The sum of \$50 was found upon him, which he had succeeded in collecting.

Examination shows a well nourished, muscular mulatto. Station: sways slightly. Gait is unsteady and incoordinate. There is very marked twitching and tremor of facial and lingual muscles with tremor of the extremities. Voice is tremulous. Reflexes: Deep, are all exaggerated; ankle-clonus is present; superficial reflexes are diminished, cremasteric absent.

The pupils are unequal—right $2\frac{1}{2}$ by $2\frac{1}{2}$ mm., left $1\frac{1}{2}$ by $1\frac{1}{2}$ mm. Irids respond sluggishly to both light and accommodation. Ophthalmoscopic examination shows early gray degeneration of both discs.

The patient is in a condition of maniacal excitement and has delusions of grandeur; talks incessantly, shouts, sings and gives commands to those around him, saying that he is equal in power and greatness to God; that he is sent by God to educate the negroes of the West, for which purpose he has already collected \$600,000,000. He boasts of his sexual power; is the father of 50,000 children; masturbates incessantly when not restrained by camisole. In a few days he became much quieter under rest in bed, baths and hypnotics (trional), but manifested delusions of persecution; threatened to kill the rascals who were poisoning him, and developed mischievous and thieving tendencies. He soon earned the reputation of being the thief of the ward, stealing papers, books and the clothing of other patients and attempting to hide these articles under his bed.

Incidents in the course of this case were: August 3, the development of tenderness over the main trunks of the right brachial plexus of nerves followed by atrophy of all the muscles of the upper extremity; synchronously with this was developed herpes zoster of the cornea (right eye) with the characteristic herpetic eruption also upon the integument of the right brow and lid. December 8, carbuncle covering entire occipital region, measuring $5\frac{1}{2}$ inches in its greatest diameter; this large area, however, was entirely filled in by granulation and subsequent cicatrization despite progressive physical and mental deterioration which was rapid. Bedridden and helpless, the four extremities paretic, sphincters derelict, and scarcely able to articulate, he would talk incoherently of his vast schemes for educating not only the negroes of this country, but of the entire world; his room was a palace and the patients and

attendants around him but slaves to do his bidding; continued to boast of his fertilizing capacity which was now 50,000 daily, and when asked how he felt would invariably reply "never better in my life." He died February 8, 1900, of paralytic marasmus or cachexia.

In this case we have with the paresis, dementia and insanity, a succession of phenomena indicating widespread neuritic degeneration. It illustrates the apparently sudden onset so frequently noted as well as the rapid progress of the disease. It is the variable form of paralytic dementia which so many writers have given undue prominence, thereby misleading the general practitioner who often fails to correctly estimate the importance of the bodily accompaniments and the dementia which constitute the peculiar or the pathognomonic features of the disease.

In striking contrast with this is the gradual onset and development of the disease in Case 1, which illustrates uncomplicated paralytic dementia; this is generally conceded to be the form most frequently encountered at the present day and is characterized by predominance of the somatic signs, viz., facial, lingual and manual tremor, defective speech, involvement of the reflexes,—of which the deep are usually exaggerated while the superficial are diminished,—manifestations of incoordinate muscular activity (disordered handwriting, awkwardness or difficulty in performing finely adjusted movements), spasms and paresis, and defect in pupillary reaction; all these accompanied by a progressive dementia variable in degree.

In etiology Case 1 prominently presents three factors: 1. Arthritic diathesis in immediate ancestry favoring the nutritive and vascular changes underlying the subsequent pathologic alterations found in paralytic dementia. 2. Cerebral instability or vulnerability evidenced in the "threatened insanity" while attending school. 3. Exposure to the most frequent toxic cause of the disease, *i. e.*, alcohol.

Lemoine (quoted by Regis¹) is of the opinion that arthritism is the predisposing cause of paralytic dementia, for which it prepares the way, by its repeated congestions and by its overproduction of the products of disassimilation, for its later development by an exciting cause, such as intoxication; (alcohol, saturnism) or infection (syphilis, malaria); Kraepelin recently considers the first cause of this disease to be a sort of intoxication from disorders of the body metabolism, which brings about alteration in the ganglion cells.

It has been repeatedly observed that in paralytic dementia the neurotic heredity is not often strongly marked and this seems to be the opinion held by the majority of alienists at the present day. Naecke, however, lays stress upon inherited or acquired cerebral defect as a predisposing cause of paralytic dementia; in a report of the result of examinations made upon 100 male paretics² he finds a high percentage of abnormal heredity and degenerative stigmata, and concludes that the disease occurs in a predisposed brain. In the examination of cases admitted to the Western Pennsylvania Hospital for the Insane during the last $3\frac{1}{2}$ years I have not failed to obtain evidence of cerebral instability or vulnerability in all cases where the source of my information was reliable. That multiplying statistics will further demonstrate the etiologic importance of this factor I do not doubt.

Alcoholic intoxication is very generally acknowledged to be one of the causes of this disease. Kellogg writes: "The toxic origin of paralytic dementia is im-

portant; alcohol is the chief toxic agent—probably not less than 15% of the cases spring from alcoholic abuse.³

No history of luetic infection was obtainable in this case. In the unsettled state of opinion regarding its etiologic importance, we must admit that syphilis has not been conclusively proved to be the only factor in the causation of paralytic dementia; it would appear that, like its congener, locomotor ataxia, it is polygenetic in origin.

Modern investigation teaches concerning the architecture of the brain, that it is made up on the same general plan as are other complex organs; that it is subject to the same laws and suffers degenerative changes in the same manner as do other organs, whether from exhaustion due to overwork, excitement or anxiety, to disorders of metabolism (faulty production or elimination, or both), or poisons from external sources (intoxications, infections). The essential lesion in paralytic dementia begins as alteration in the nutritive state of its functional unit progressing to permanent structural change.

It is not always easy to discover the exact part played by each element in the production of a disease the onset of which is so insidious that "its origin is lost in the darkness of the past," but we may assume that paralytic dementia is the result of a series of causes acting sequentially or in combination and in varying contributive degrees.

PUERPERAL ECLAMPSIA, WITH REPORT OF TEN CASES.

By J. B. TODD, M.D.,
of Syracuse, N. Y.

In my experience cephalalgia is the danger-signal of coming eclampsia. A woman may have slight albuminuria and under proper care even recover, but if during labor and for two days afterwards the patient complains of severe pain in head there is danger of eclampsia.

In the treatment but slight reliance should be placed on diuretics, especially in digitalis and potassium acetate, which depress the heart but do not eliminate the urea. Hydragog cathartics are required to eliminate the poison or toxin and should be followed by iron and mercuric chlorid.

R.—Tr. ferri chlor. 1 ounce.
Hydrg. bichlor. 1 grain.
Ft. sol. Sig. Twelve drops in a capsule every 4 hours.

To control the convulsions there is nothing like morphin, provided it is given in sufficiently large doses. From $\frac{1}{2}$ to $1\frac{1}{2}$ grains should be given hypodermically, and the headache will be the criterion to tell you when to repeat the dose.

Whenever the patient complains of severe pain in the head give another dose, whether it has been one hour or longer since the last dose was given.

In the meantime give the hydragog, and I prefer elaterium because it may be depended upon to produce a thorough action.

I append brief notes of 10 cases which have occurred in my practice.

CASE 1.—Mrs. S., aged 17, was delivered of her first child without any trouble, but on the second day complained of headache and soon had a convulsion. I gave $\frac{1}{2}$ grain of morphin hypodermically. She had no recurrence of convulsions and made a good recovery.

CASE 2.—Mrs. H., aged 15, about 2 months pregnant, complained of headache and at 9 A.M. had a convulsion. For the time $\frac{1}{2}$ grain of morphin relieved her, but at 2 P.M. the condition returned and she soon had another convulsion. For the next 36 hours she would have a recurrence of pain in the head to be followed by a convulsion whenever the morphin became exhausted. The urine was scanty and highly albuminous; the entire body edematous. The morphin was given in increasing doses, until, from 5 to 9 A.M. on the second day, she received 4 grains and during the next 24 hours 8 grains. This quantity was not guessed at, but carefully weighed. She was not narcotized at any time, just quiet, and whenever there was a recurrence of pain in the head a hypodermic dose of from 1 to $1\frac{1}{2}$ grains of morphin would prevent the convulsion. As the kidneys did not eliminate the urea she was given elaterium, which produced a large number of watery evacuations from the bowels. The patient rapidly regained her normal condition and in 4 months expelled the placenta with the fetus macerated and absorbed. I have since attended her in 3 labors with no trouble.

This case would seem to show that it is not necessary to produce an abortion in every case of eclampsia occurring in the early months of pregnancy.

CASES 3, 4, and 5.—The next 3 cases were in women aged 29, 30 and 38. All had borne children, and in each there was headache during labor, and in each a single convulsion occurred shortly after labor, the hypodermic dose of morphin preventing any recurrence.

CASE 6.—Mrs. B., aged 19, labor at term, had a convulsion in the morning. An eclectic practitioner was called and remained with the case from 2 until 5 P.M., when he left. I saw the case at 9 P.M. She had had four convulsions and the child was dead. The woman died in a convulsion within a few moments.

CASE 7.—Mrs. S., aged 27, first child, she weighed 200 pounds. Labor had progressed through the first stage when she had a convulsion. I gave $1\frac{1}{2}$ grains of morphin and chloroform until she was unconscious, and delivered with instruments. Mother and child both did well.

CASE 8.—Mrs. H., aged 17, first child, at term, had slight labor-pains in the morning soon followed by a convulsion. I saw her at 10 A.M. She had already had two convulsions, and was semi-conscious but moaning with pain in head. I gave her 1 grain morphia sulfate and chloroform. The os was but slightly dilated, and I stretched it with fingers until forceps could be applied at superior strait. A living child was delivered and the mother made good recovery.

CASE 9.—Mrs. R., aged 31, the mother of one child, 3 years old, had slight albuminuria for 2 or 3 weeks previous to that confinement, and 3 hours after her delivery she had 8 or 10 convulsions, and was slow in her recovery. She became pregnant the second time in June, 1898, and except for being quite nervous she enjoyed good health until about the middle of January, 1899, when she began to have pain in the occiput, extending down the back of the neck.

At that time the urine was slightly albuminous, and she continued in about the same condition until February 7, when labor began. At 10.30 A.M. she was delivered of a female child, which weighed 3 pounds 5 ounces. She had headache. Her urine was scanty and albuminous, and her breath had uremic odor.

She had a convulsion at 1.30 A.M., February 8. I gave her 1 grain of morphin hypodermically and 3 grains of a 5% triturate of elaterium. The headache was relieved, but she did not sleep. At 9 A.M. I gave $\frac{1}{2}$ grain of morphin and 3 grains of the elaterium triturate. The bowels moved at 11.30 and 8 times to noon of the 9th, with large quantities of watery evacuation. The morphin, in $\frac{1}{2}$ -grain doses, was continued every 4 hours until the 10th, when she had 6 more watery evacuations. Her condition was now improved. She was put on tincture of the muriate of iron, 10 minims, and mercuric chlorid $\frac{1}{6}$ grain every 4 hours, and made quick recovery.

The babe was wrapped in cotton batting and kept on a tin water-bottle and fed every 2 hours with pasteurized milk, diluted one half, with cream added, and peptonized. At the present time it is a strong, healthy, child.

CASE 10.—Mrs. M., aged 21, in her second labor, September 9, 1899, was delivered in 2 hours. Her face was edematous and her feet swollen. Shortly after delivery she had a convulsion, and I gave her 1 grain of morphin hypodermically, afterwards putting her on iron and mercuric chlorid, and she made a quick recovery.

RECAPITULATION.—In 6 cases after labor there was a single convulsion; all recovered.

In 2 cases during labor. In one case there was a single convulsion, and in the other several. Both children and mothers lived.

In one case in the second month of pregnancy the patient carried the fetus for 4 months without the slightest inconvenience.

In one case, abandoned by an eclectic, death ensued before remedies could act.

REPORT OF A CASE OF RUPTURE OF THE PERINEUM IN COITUS.¹

By R. ABRAHAM, M.D.,

of New York.

District Physician to the Mt. Sinai Hospital; Attending Physician to the Skin and Genitourinary Department, East Side Dispensary.

I REPORT an accident which is of extremely rare occurrence. According to a recent observer² medical literature contains but 22 recorded cases of rupture of the perineum in coitus.

My patient, Mrs. X., is 26 years old and was married in the latter part of December, 1899. Prior to her marriage she enjoyed perfect health. Her menstrual periods were regular, and she never complained of pain in or around the genital organs. She never had a prolapse of the rectum; never had hemorrhoids; never had an ischiorectal abscess, nor swelling or inflammation of the perineum. At the first intercourse the hymen was ruptured and a small quantity of blood escaped. Within a period of 6 weeks subsequent to their union the young couple cohabited from 6 to 8 times. In her last coitus she experienced "some little pain." This last act was attended by a considerable amount of bleeding. This unusual accompaniment of the sexual congress was interpreted by the young husband and wife as the last blow to the hymen, or, as my patient quaintly puts it, "the finishing touch to virginity." When, however, she made her morning visit to the lavatory she was amazed to find the feces escape from two places, the anus, and at a point higher up, near the vulva. She then consulted her mother, who in turn brought her for consultation to me.

On examination the external genitalia were found well developed and perfectly normal. There was the usual vestige of a hymen. Digital examination was neither difficult nor painful. The vagina and uterus were normal. The perineal body presented a tear which extended almost over its entire width. In examining this tear it was found that the penetration and rupture of the perineum were complete and perfect, just as if both were made by design and suitable instrument. There was very little laceration about the wound. First one and then two fingers were introduced into the opening. The examining fingers entered the rectum and encountered a large mass of fecal matter. A bivalve speculum was inserted and by distending its blades and getting rid of the feces a good view of the rectum was obtained. Careful examination failed to reveal any recti-vaginal or recti-vulvar communication. The rupture was clear through

the perineum into the rectum. It was what one would call a recti-perineal fistula. A finger in the anus could easily be made to go through the artificial opening, and vice versa.

I wish I could record the treatment. It seems that the unhappy bride was so terribly overwhelmed with this unspeakable accident that when she was told the nature of it and the best method of remedying it, namely suturing, she went and never returned, though she left me in possession of sufficient data to put her interesting but unfortunate mishap on record.

Epidemic Jaundice.—The *China Medical Missionary Journal* of January, 1900, contains, on pages 63 and 64, some notes by Dr. James Boyd Neal on an epidemic of jaundice which prevailed during the autumn of 1898 in Peking and Tientsin. During the past autumn of 1899 a similar epidemic has been very prevalent in many parts of the province of Shantung. In the eastern part of the province the disease has been comparatively light; no dangerous or fatal cases having come under the observation of the writer, though he has heard of a few deaths, supposed to be due to the disease, among pregnant women. The disease begins with vague feelings of discomfort and heaviness in the epigastrium, scarcely distinguishable from an ordinary attack of indigestion, accompanied with heightened color of the urine. There is no chill nor fever to indicate the ushering in of the disease. The feeling of discomfort in the pit of the stomach increases in severity, and is prominent throughout the attack; the color of the urine continues to deepen and stains the clothing yellow, giving in every case the reaction for bile coloring-matter with nitric acid; the sclerotics show a deep lemon color, which is so marked that the Chinese call the affection the "Yellow Eye Disease," while the skin, especially of the face, neck, and body, shows marked jaundice, and becomes decidedly itchy. The foreigners who have come under the observation of the writer, have none of them gone to bed, but have gone on with their usual duties, though with great discomfort, but the natives have, as a rule, taken to their beds, and in some cases have been laid aside from active duty for a fortnight or more. Indeed the Chinese seem to have had the disease more severely than foreigners. The above is a description of the disease as seen by the writer in Eastern Shantung and on the seashore. Dr. Faries writes from Wei-hien nearer the center of the province and in the interior: "There is a continued ill feeling in pit of stomach, and then pain in stomach and back, and most obstinate constipation; ten grains calomel and jalap not affecting the bowels. When the bowels move there is a complete absence of bile. Wheat-eaters' passages are as white as chalk. The urine is scanty; high-colored, reddish, or deep yellow, and stains clothing yellow. The eyeballs become yellow, and in a severe case the skin becomes very pale and yellow. The patient becomes very anemic, and the case runs for a month. In some cases the distress in the stomach causes great nausea, and also vomiting of blood. The pulse-beats are from 58 to 70 in the jaundiced cases, and in the early stage the pulse is not rapid. The first stage sometimes ends in profuse perspiration, or there may be several sweats with chills between. Some tell of an initial chill. Pain in eyeballs is frequent. The liver seems to be the organ most affected and the last to recover. I have neither seen nor heard of an eruption. A very great many pregnant women have been taken suddenly with great distress, then become delirious in a few hours, then comatose, with eyes closed and tongue out, then they abort and die, or perhaps die before aborting; the uterus making violent efforts. Eight women died in one street in the east suburb. Some men have died of the yellow-eyed disease with dropsy they say." Nothing in the way of treatment seems to affect the course of the disease, though doses of calomel and bicarbonate of sodium relieve the constipation, which is found in some cases, and seemed, in the writer's case, taken when the passages became white, to help restore the functions of the liver. It seems to be a self-limited affection, running its course like the ordinary acute infectious disease. Some of the Chinese say that just such an epidemic of jaundice prevailed in Shantung some thirty years ago, on the occasion of a drought equal in severity to the widespread dryness which is now affecting all North China. [M.B.T.]

The Dangers of the Railroad.—That the arts of peace are not less dangerous than those of war would appear to be amply indicated by the figures of railway accidents for a year. According to the twelfth statistical report of the Interstate Commerce Commission, one among every 420 of the 417,508 men engaged in the work of railway transportation was killed, and one among every 27 was injured during the year ended June 30, 1899. Of trainmen proper, engineers, firemen, conductors, brakemen, baggagemen, etc., one was killed for every 155 employed, and one injured for every 11 employed. The total number of accidents among employes was as follows: Killed, 2,216; injured, 34,923. Of 523,000,000 passengers carried only 239 were killed and 3,442 injured. A good deal has been done to reduce to a minimum the dangers attending railway travel, but much remains that can yet be done, and the promise seems not extravagant that the time will come when there will be no more risk in traveling by rail than in any other form of progression or locomotion.

Hit by the Eclipse.—The recent eclipse of the sun does not seem to have been prolific of superstitious displays in the United States, and therefore we all the more welcome an amusing instance related by Dr. W. H. Morse in the *Albany Medical Annals* (July, 1900). According to Dr. Morse, it is the custom in Cuba for mothers to expose their young children entirely naked on the ground during the whole time of the obscuration of the sun or moon, in order to prevent their being "hit by the eclipse"—and, incidentally, by any devils that may be lurking about. If the child takes bronchitis, it is "hit;" if it escapes, it is blessed. This superstition clung to a Cuban woman living in New Jersey. She accordingly exposed her two infants, aged 3 months and 14 months, respectively, during the whole eclipse, with the result that the unfortunate innocents both took severe bronchitis. The husband, going for the doctor, announced, in terse Spanish, that "a mother and two daughters are three devils for a father." At the same time the priest was summoned, and he, being a level-headed and good-natured Irishman, lost no time in saying prayers, but took the doctor's prescription to the drug store to have filled. Fortunately no harm resulted, for the babies, after severe illness, recovered. The mother, of course, believed that they had been "hit by the eclipse," and gave all the credit for their

cure, not to the doctor, but to the priest, and especially for the splendid "holy water" which he had brought, and which was the doctor's prescription for eucalyptol!

Positive Prevention and Cure of Tuberculosis by the Nature-Cure Process, for both the Profession and the Laity. There is need for authority to revoke the privileges conferred by license to practise medicine from those who unworthily use or abuse such privileges. Charlatanism and quackery should not be tolerated, even though practised by one who holds the diploma of a recognized medical college and a certificate to practise medicine. These remarks are prompted by a pamphlet with the title that appears at the head of this note, issued by a man who appends Ph.D. and M.D. to his name and who appeals, among others, to physicians for a trial of his treatment. The novel proposition is made that "all forms of disease arise from one cause, viz.: the presence of unnatural substances in the body," and it is modestly claimed that "the methods described in this volume have proved an absolute panacea for all forms of disease, such as blindness, cancer, diabetes, Bright's disease, syphilis, insanity, epilepsy, etc., etc." Now these statements are so palpably absurd that they will not be given consideration by any one of even ordinary intelligence, and we refer to the subject only to illustrate the necessity for some means of controlling medical practice by those upon whom this privilege has been conferred. Too often the opportunity for successful treatment is lost through resort to methods that can result only disastrously, in consequence of the cupidity of men who do not scruple to make the sick, the maimed, the dying, their victims.

Mr. Brockway's Retirement.—When a man has done a great work in penology, such as the recent superintendent of the Elmira Reformatory has conspicuously done, and retires from his labors, it is a pity that his retirement should be made the occasion for criticism and controversy as to the merits of his work. It is still greater pity that his retirement should be made to appear forced. Mr. Brockway, if we are well informed, has reached a ripe age, and is entitled to repose; but as a competent public servant he should not be obliged to appear to be vacating his office under something of a cloud of misunderstanding. Mr. Brockway's name is closely identified with the system in vogue at the
